

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. ON SYPHILIS. (a)

By JONATHAN HUTCHINSON, LL.D., F.R.C.S.,
F.R.S.

It is now well recognised that syphilis stands side by side with the exanthemata, that it is a febrile disease, having quite definite stages, and that it must have necessarily from that fact a particular virus which breeds in the blood and produces the various phenomena associated with the disease. The stages have been classified, as all know, into primary, secondary, and tertiary. That classification will never be set aside, although it must be fully recognised that it is not one which can be applied with very great strictness. We know what is meant by the primary stage of syphilis, namely, the stage of inoculation or introduction of the virus, characterised usually by the formation of what is known as a primary sore, a chancre. The secondary stage is the febrile stage, during which an eruption comes out on the skin of the patient and on the mucous membranes, and during which there is a certain amount of febrile reaction. So the primary or first stage is a local one, and the second is a blood stage, in which the virus is in every portion of the blood. The secondary eruption will be accurately symmetrical, proving clearly that it is a blood disease. In the third stage, to which the name tertiary is given, the symptoms are no longer symmetrical, they no longer imply blood disease, and the patient is no longer capable of communicating the virus to anyone else. The symptoms of the tertiary stage concern the solid tissues and not the blood.

We will now consider the peculiarities which attend the inoculation, or, in other words, the primary sore. We all know that what are called chancres differ very much in their features. In book descriptions of chancres it is sometimes implied that the primary sore of syphilis is always indurated and sclerosed. There are very many exceptions to this. Syphilis does tend to produce very remarkable sclerosis in some cases, but it does not do it in all, nor does it do it in all parts. For practical purposes the most definite examples of sclerosis in connection with a primary sore may be said to be met with only on the genitals. It is said that on the female genitals you scarcely ever meet with indurated sores. That is a mistake. They are frequently overlooked and they are seldom so characteristic as those met with on the genitals of the male. On the genitals of the male we often

meet with a form of induration, especially just above the corona, as hard as cartilage, which is quite specific, and which, to those who have become acquainted with it, is pathognomonic. Fifty years or so ago, the distinction between the hard and the soft chancre was strongly drawn—that is to say, the distinction between what I prefer to call the infective and the non-infective chancre. We do not nowadays hear anybody talking about dualism in syphilis, we recognise that there are sores which are non-infective as well as those which are infective, but that there are two kinds of syphilis and that the word dualism is in any way applicable no one nowadays dreams of. In investigating syphilis we are not dealing with the introduction of a pure virus; there is no such thing as a pure culture in the case of syphilis. It is introduced in a mixed state in the great majority of instances, and it is owing to that mixture of pus and other secretions, and to the accidental way in which syphilis is conveyed, that we owe the multiplicity of appearances in the primary sores. The incubation stage, prior to the appearance of any sore, before the place which has been inoculated will inflame in any degree whatever, will be at least three weeks, probably a month, and possibly five weeks. The sore on its first appearance will be simply a little papule or red patch or spot which may be observed for a few days. It will take a week before anything in the nature of specific induration, which you can estimate with the finger, will be produced. If no sore has appeared until the end of nearly four weeks, it is probable that it will indurate within a week of its beginning to such a degree that it may be recognised as an infective chancre. In some cases other sores due to the introduction of the products of inflammation, pus and other poisons are present, and the elements which the pus may contain may produce a sore which may take precedence of a true chancre. A patient may have a non-indurating chancre which was never at any stage "hard." The absence of induration is all that we should take cognisance of; "softness" is not in itself a positive feature, not anything pathognomonic, to which we can trust. For practical purposes I warn everyone most strongly never to tell a patient who has got a sore which may possibly have been contracted by a venereal source that he has not got syphilis until a month has elapsed, because it is not till then that you can judge; the syphilis may be absolutely latent, or it may be entirely concealed by the presence of something else, such as an inflamed, sore until that period has elapsed. Hence my idea of the relationship between the non-indurated sore and the indurated. The sores

(a) Abstract of a Lecture delivered at the Medical Graduates' College and Polyclinic, October 21st, 1902.

which are not indurated are the result of various forms of pus contagion, and they may very often carry with them the virus of syphilis.

The peculiarities presented by the sores called "soft" vary very much indeed. Multiplicity is one of the features in which the non-indurated sore differs from the indurated. The secretion of pus is another. But an indurated sore may also be multiple, and four or five up to fifteen indurated sores have been noticed together. On the other hand, non-indurating sores may be single. But in proportion to the shortness of the period intervening between the contagion and the appearance of the sore so may you feel sure that the sore is not as yet syphilitic. This does not exclude syphilis afterwards, but it makes it pretty clear that that sore, as at present seen is not due to the syphilitic virus, that virus producing nothing until at least three weeks have elapsed. In the true indurated Hunterian chancre it is usual for the glands in the groin to be enlarged and to become very hard. The expression "bullet bubo" is a very proper one. The chancre may be as hard as cartilage, and the swelling in the glands of the groin may be as hard as bullets, quite movable, that is, not becoming glued together. Here again the tendency of the syphilitic virus is to cause an adhesive inflammation with fibrinous exudation, a tendency to organisation and not to suppuration, whereas in the other form there is a tendency to suppuration. But just as the sore itself is inflamed and ulcerated, so the bubo which results from it is inflamed and tends to suppurate. But none of these features of distinction must be pushed too far. The bubo of true syphilis may also suppurate, and this we witness not very infrequently. There is a chance also, of course, that the other form may not suppurate; indeed, it is only exceptional that it does so.

A useful point in diagnosis is to examine the glands. If you find hard glands in the groin the inference is there has been a chancre at the anus, on the perineum, or on the genitals, and if you find a hard bubo in the armpit that the hand has been the seat of infection. Whilst I believe that there is such a thing as syphilis without any obvious chancre, I have no doubt there is in most of these cases some trivial sore, and it must in some be trivial to a minute degree, because observant patients and surgeons often fail to identify it. In the cases of surgeons who get syphilis after having their hands exposed in midwifery practice, and who yet never recognised a chancre, I suppose the virus has probably been lodged by the side of the nail. Surgeons have become the subjects of syphilis from rather deep pricks with needles which were poisoned. In one case a surgeon had pricked himself in the thumb with a needle when operating on a syphilitic patient. The site of the prick was a little tender for some time, and then there was just the slightest brown discoloration around it, and that was all he had in the way of chancre. In a great many cases the sore is not a characteristic one; we are far too much in the habit of insisting that the primary sore of syphilis should always be a well characterised, indurated chancre. If we can have syphilis without a chancre in the case of pricks it is possible it may follow sores on the genitals which never indurate. In the diagnosis of primary syphilis we, of course, pay great attention to induration, for when it is present, it is a symptom which is beyond appeal. If there is

no induration whatever in the glands, that is another reason for doubting specific inoculation, but the omission of induration of glands is not infrequent in syphilis, and we must not, therefore, trust too much to it.

Anyone who has any doubt as to the influence of mercury upon syphilis, or upon the sclerosis produced by it, may easily convince himself. Give a patient with an indurated sore mercury and it softens in a few days, then melts away. Stop the mercury and it indurates again, resume the mercury and it again softens. As to the question whether the chancre will disappear without treatment, I believe that a primary chancre will usually disappear spontaneously in a month or six weeks, but it is difficult in the present day to get facts which help in this direction, because everybody gives mercury as soon as the disease is recognised. The induration will certainly go away except in the rarest cases after a period of induration of a few months. The secondary stage of syphilis will often begin while the primary one is still existent. It is a rule if the patient be not treated, for the symptoms of blood poisoning to begin to manifest themselves long before the primary induration has disappeared. The peculiar feature of indurated chancres is recrudescence. By recrudescence of the chancre I mean its spontaneous reappearance after a considerable period in the precise locality in which the first appeared without any fresh inoculation whatever. The induration induced is exactly like that of the original one, so that anyone who is not familiar with the fact that a recrudescence is possible would certainly be inclined to doubt his patient's statement, and to believe that he had contracted a fresh sore. There are two or three other peculiarities which the primary sore may assume; one is that it may cause not a hard ulcer but a fungating growth. This is important, because it has been this kind of sore which has been claimed as peculiar in a case of yaws. Whilst a primary chancre may sometimes never ulcerate at all, it is sometimes nothing but an ulceration. Primary chancres have been cut out in mistake for tumours because they were not ulcerating, the skin around remaining perfectly sound and soft.

It has been customary to say that the soft chancre never occurs anywhere but on the genitals, but as a matter of fact almost all sores which occur on the tongue, lips, skin, or other parts are infective. These are not all indurated. I have seen on the fingers definite induration, but in the majority of cases you must not expect to recognise specific induration in an erratic chancre.

As regards the secondary symptoms and the period of their appearance in round figures, we will say that two months must elapse before the secondary symptoms begin. The patient at that time will become a little feverish and will probably have an eruption on the skin, and that eruption will perhaps be in the first instance roseolous, an eruption which very probably may be overlooked by the patient. That eruption is quite transitory and is usually followed in the course of two or three weeks by a papular or mixed one.

With regard to treatment, I entertain no doubt that mercury may be regarded as a specific against the syphilitic virus. It removes the indurated chancre and prevents the secondary symptoms. Of the latter fact I make no question whatever. The symptom which it least constantly prevents

is the sore throat; indeed, mercury often causes sore throat, but there will be no skin phenomena whatever. The inconveniences attending the use of mercury are the salivation and diarrhoea. If a patient is dieted while he is taking the mercury he will not have diarrhoea. Every kind of fruit and all green vegetables should be forbidden, and the patient should live simply upon beef, mutton, fish, and potatoes and bread, and an opium pill can be given if necessary to prevent diarrhoea.

SOME CASES OF TUBAL DISEASE TREATED BY OPERATION.

By E. H. TWEEDY, F.R.C.P.I.,
Gynaecologist to Steevens' Hospital, Dublin.

THE following cases of grave tubal disease which have comparatively recently been under my care and operated on by me in Steevens' Hospital I consider worthy of publication. They each present features of interest, more especially from a diagnostic standpoint; and demonstrate some few of the conditions liable to be encountered when operating for the relief of symptoms induced by diseases of the uterine adnexa.

CASE I. is an instance of tubal mole. The patient from whom it was removed was last unwell on March 17th, 1902. On April 14th she suffered from a flooding, and supposed herself to have miscarried. From that time on irregular hæmorrhages occurred until she came under my care five weeks later. On bimanual examination a large, retroverted uterus with softened cervix was felt, and an egg-shaped tumour lying to the left of this was palpated.

On June 2nd the tube was removed, the uterus being at the same time stitched by its posterior wall to the peritoneum of the anterior abdominal wall.

A section, kindly prepared for me by Dr. Earl, shows clearly the nature of the tumour. The tube had not ruptured. Neither did it contain any active elements of growth.

A case such as this demonstrates how very important it is to discover some means whereby we could distinguish between a dead and a living fetus in tubal pregnancy. I am convinced that the cervix and lower uterine segment lose much of their characteristic feel in the presence of a dead ovum in utero, but as to whether a similar change occurs with a tubal mole my experience does not permit me to say.

CASE II.—Pyosalpinx of tuberculous origin, chiefly interesting because of its accidental discovery. The patient from whom it was removed was a pale-faced, emaciated woman, æt. 27, married three years, sterile, who had suffered on three different occasions since marriage from peritonitis. She stated that the last attack—a very severe one—had occurred a few weeks before coming under my care in the early part of last September.

On bimanual examination a cystic tumour, somewhat larger than the normal uterus, was felt in her right iliac region. The left tube was palpated, but neither it nor its corresponding ovary gave me the impression of being diseased.

On September 10th I operated for the removal of the tumour, which I had fully made up my mind was the cause of all her suffering.

This, however, proved to be a simple broad ligament cyst free from adhesions, or any other sign of

inflammation. The thin and much-drawn-out tube lying on the top of the tumour was at the same time removed.

On examining the other tube I found it thickened, bent on itself, and occluded at its abdominal mouth. This was unfolded, and then a probe was forced through its lumen, with a hope of correcting the sterility. Pus, however, welled up by the side of the probe, which necessitated the prompt excision of the tube. The microscopic specimen shows clearly its tuberculous origin.

Baldy states that normal tubes cannot, as a rule, be palpated, and with the experience of this case before us I am inclined to subscribe to the truth of this statement.

CASE III.—The third case on my list came under my care in Steevens' Hospital last September.

She suffered from a tumour situate in the left iliac region, very tender to the touch, and easily palpated above Poupart's ligament.

She was married for some years, sterile, and gave a history of two previous attacks similar to this one.

She had a hectic temperature for the first week after admission, rising in the evening to 102° F. It fell each morning to normal. During the second week it gradually subsided, and became normal at the end of fourteen days.

The swelling in her side progressively decreased, and on October 9th, the day before operation, was felt by bimanual manipulation to be about the size of a small orange.

The operation was undertaken only at the patient's urgent request, as she had shortly to sail for India, and feared a repetition of the inflammation.

On opening the abdomen a thickened and much bent tube was removed, which, when examined, showed no trace of purulent contents. A microscopic section of this demonstrated a small-celled infiltration, the origin of which could not be determined.

It is, I think, reasonable to conclude that this tube contained a considerable quantity of pus a short time before operation. There was no history of vaginal discharge, and the absence of adhesions between tube and intestine excluded the view that pus might have made its escape into the latter. It is, I think, difficult to account for the changed conditions here present in a manner other than that a rapid absorption of an acute abscess took place. In consequence of the fat condition of her abdomen I was much exercised in my mind as to whether I should select the vaginal or abdominal routes for operation. I am pleased to say that the latter was finally selected.

CASE IV.—Mrs. R—, æt. 29, married four years. Had twice suffered from peritonitis. The first attack six months after marriage. The second—a very severe one—occurred eighteen months ago. Her uterus was enlarged and firmly adherent in a retroverted position. The tubes did not appear enlarged, but their unelastic and brawny feel gave clear indication of disease. The woman suffered from a constant severe abdominal pain which a former curettage and free purging failed to alleviate.

Operation, November 20th.—On opening the abdomen the omentum appeared firmly fixed to the anterior abdominal wall and bladder. On its under side the small intestines were adherent to it. Its separation was most difficult, and was finally

accomplished by cutting it across. This enabled the intestines to be disentangled and the uterus to be reached. Before the latter could be brought forward it was necessary to drag the much-diseased left tube from its bed of adhesion tissue and remove it. The ovary seemed fairly normal, and my first intention was to spare it. The free oozing, however, which took place from the adhesion bed necessitated its removal.

The other ovary and tube were left behind, and the uterus fixed to the peritoneum of the anterior abdominal wall by one buried silkworm-gut suture.

This case demonstrates how much superior the abdominal route is to all others when dealing with a fixed retroversion.

The adherent omentum and intestines situate in front of the uterus would have rendered any other route abortive.

In conclusion, I have only to add that all these patients made a febrile and uneventful recovery.

THE TREATMENT OF STRABISMUS. (a)

By EDGAR A. BROWNE, F.R.C.S.

Consulting Surgeon to the Liverpool Eye and Ear Infirmary; Lecturer on Ophthalmology, University College, Liverpool, &c.

On every side in examining the progress of the mixed art and science we call Medicine, we see the two separate lines derived from empirical and scientific starting points. When the empirical observations lead to a sufficiently successful line of treatment, a false sense of satisfaction is engendered which prevents a more profound investigation. It is always more easy to accept the obvious than to search for the hidden. In the history of squint are two eras—the era of Diefenbach, who, with his followers, recognised the obvious misplacement of the eye in relation to the palpebral aperture, and remedied the deformity by cutting the (supposed) offending muscle. Subsequent improvements in technique have rendered it possible for anyone with a moderate degree of skill in ophthalmic surgery to turn an eye in any desired direction. Indeed, so successful in appearance are operations on the muscle that squint is regarded as a muscular affection, and innovations in treatment are regarded with suspicion. There is no probability that the operations for squint will be discarded in any reasonable length of time (indeed they must always remain useful in neglected cases), but they are purely empirical proceedings and are sure to give way before a rational knowledge of causation. The era of Donders is that of the slow co-ordination of exact observation of actual facts and their relative importance that constitutes science. Donders' "theory" is often spoken of, as other "theories" are, as if it were something outside the range of practice. From Donders will proceed the rational treatment of the future. He bequeathed two legacies, one a generalisation, that hypermetropic eyes squinted towards the mesial line and myopic eyes squinted out. This remains true, and the measurements afforded by the Maddox-rod of small degrees of latent squint (or heterophoria) tend to show that the rule has a wide application. But his explanation of why hypermetropic eyes squint is probably only partially true. He accurately noted the relation between accommodation and convergence, and surmised that a patient making undue con-

vergence was afflicted with diplopia, and therefore looked straight with one eye, and squinted double with the other. The second image, therefore, falling in a comparatively insensitive part of the retina, was easily suppressed. So far from this being true, one of the difficulties in treatment is to provoke diplopia, and from that basis restore binocular vision. But Donders effectually threw attention on to the optical nature of squint. The muscles are not at fault. Their contraction is due to their motor centres causing them to perform their natural functions, and we have to search for the cause that sets the centres in action. Squint is not a disease. Its onset is regular—always at the same period of life, always on the same lines, and in the same stages. It is an accident of development. The stages are (1) potentiality—a period which every child whose ocular development is not proceeding regularly may pass into; (2) periodicity—when squint takes place occasionally under excitement or strong desire to see; (3) habitual—when fixation with one eye only is the rule, but when parallelism is likely to be restored in sleep, under chloroform, &c., from this two separate developments may occur; (4) a secondary periodic stage not mentioned in books, ending in recovery; or (5) stage of permanent deformity, involving distortions of capsule of Tenon, &c., and demanding operation for cosmetic considerations. Attention had been too strongly fixed on convergence as the essential fact of squint, but it is the last link in the chain of events. An intimate relationship is found to exist between amblyopia and squint. In the vast majority of cases in the permanent stage, a pronounced amblyopia is found, affecting chiefly the central retina. There are grounds for believing that this may be wholly a faulty development; its regularity excludes disease. The hypermetropic eye is an incomplete eye, and its nervous elements may in certain cases be reasonably supposed to be that of a slow development. The sense of vision requires practice as well as natural endowment, and if from a higher hypermetropia or astigmatism one eye was more deficient in clearly-formed images than the other, it was likely to lose its instinctive desire for sharp focussing, and become poorly developed from want of exercise—like any other function. There is no sense of diplopia when there is a clear image in one eye and a blurred image in the other. The intimate relationship of squint with amblyopia is sometimes shown when central choroiditis, corneal ulcers, or even a pad on one eye will provoke a squint in a child. There is no particular reason why both eyes should be directed to the same point except for stereoscopic vision and the desire to avoid images on incongruous tracts of the retina. So when the desire is latent, the natural action of the muscles is likely to assert itself and we see an unnecessary convergence taking place. What we really see is a primary position of convergence on to the mesial line at a useless near point and conjugate deviation to the side of the better eye.

Hypermetropia is not the cause of squint, but exhibits the most favourable conditions, especially in the matter of exercising the muscles of convergence. Therefore squint may equally occur in young myopic eyes, before the internal recti have lost their preponderating power, if the other conditions are fulfilled. Squint, therefore, is a failure in a peripheral sense-organ to acquire its

(a) Read before the Liverpool Medical Institution, December 18th, 1902.

complete function leading to independent and uncontrolled action of the motor centres of the internal (and in part superior) recti. Initially nothing takes place but what is natural, but in later stages deformities and secondary changes become developed. Treatment has for objects restoration of desire for (1) distinct vision, and (2) binocular vision, and (3) diminution of accommodation effort. The obstacles to success are numerous and difficult to overcome. Prevention of squint can hardly be expected till the general practitioner co-operates with the specialist, and superintends the treatment in the homes, and supervises the ocular hygiene of children in schools.

A CASE OF PAROXYSMAL TACHYCARDIA. (a)

By JOSEPH O'CARROLL M.D., F.R.C.P.I.
Visiting Physician to the Richmond, Whitworth, and Hardwicke Hospital.

TACHYCARDIA is well known as a symptom of many organic diseases or functional disorders. Its pathology in these cases is closely bound up with the original or causative disease, and may be almost as various. But in certain cases, in which no organic disease can be detected, and in which no constant functional derangement seems to be present, tachycardia, paroxysmal in character, and alone or accompanied by symptoms which are largely subjective, may come under observation. Of these cases there is no satisfactory explanation, no ascertained causation, and no morbid anatomy to record. They do not lend themselves readily to any label such as gout, or hysteria, or neurasthenia; nor can they be referred decidedly to one sex or the other (though no doubt women suffer most), nor to the disturbances of any critical period, whether adolescence, the menopause, or senility. If there be any group of circumstances to which any considerable proportion of such cases is to be referred, it will perhaps be that which embraces fright, anxiety, overwork, or, generally speaking, acute or prolonged overstrain, whether of body or mind. But how these act in producing a liability, extending perhaps over many years, to attacks of very rapid pulsation of the heart interjected into the normal cardiac life we are quite at a loss to explain. It is just in such questions that theory runs riot; yet we can only cease to theorise when we cease to think. In such obscure conditions as idiopathic or paroxysmal tachycardia it is permissible to base theories of causation on the results of physiological experiment in animals, on the clinical observation of concomitant symptoms, and on the results of treatment.

Of tachycardia physiology can offer no reasonable explanation; it has little knowledge of any mechanism or agent by which the normal heart rate can be multiplied four times for hours or days together, without any apparent damage to the organism or the organ. We are thus thrown back upon clinical and therapeutic observation, and it is because the case I am about to relate seems to give some hints as to causation derivable from both its symptomatology and its therapeutics that I venture to bring it under your notice.

A governess, æt. 34, unmarried, was put under my care in hospital by my colleague, Dr. Harvey, on July 15th, 1901. She was a tall, healthy-look-

ing lady, highly intelligent and well educated, who had supported herself for some years by teaching. She lives alone; moves about much every day from tuition to tuition; and occupies her evenings either with literary work or with night classes. Her father is alive; her mother is stated to have died some years ago of bronchitis; and a sister died also, but my patient does not know of what disease.

The patient states that she enjoyed excellent health until June, 1887, when she first got attacks of pain in the chest. Later on in the autumn she had two further attacks, and then she had freedom from them till August, 1892. A further period of good health followed until 1898, but in that and the two following years she had several returns of the pain. In February, 1900, the attacks began to be much more frequent than previously, coming on during the first six months of the year about five times a week. She has a tendency to constipation; menstruation has been pretty normal.

On admission it is seen that she is by no means anæmic; is muscular, but not fat; there is undue gastric tympany. She is of a cheerful, non-anxious, non-introspective disposition. Lungs apparently normal. Urine normal. Heart sounds normal; area perhaps slightly increased, but her thorax is spare; pulse 44 beats in the minute, regular, and of medium tension. She describes the attacks from which she suffers as follows:— They come on with dimness, which sometimes reaches complete loss of vision; then great pain in lower sternal region, with rapid action of the heart. The pain may last from ten minutes to ten or twenty hours, the shorter period being much the more usual. These attacks bear no constant relation to meals, nor to abdominal flatulence, nor to muscular exertion. In fact, they occur usually when she is in bed, at muscular rest, and are not likely to be caused by running to catch a tramcar or train. Breathing is not interfered with, and there is no fear whatever of impending death. Involuntary micturition has never occurred in the attacks, but once or twice she has lost consciousness, from, she says, the intensity of the pain.

On July 25th, her case-sheet records that she had fifteen short attacks. "It appears," says the note, "that in a typical attack there is noticed at the outset a dazed expression with pallor of the face, some agitation and trembling. She sits up in bed, and grasps the sides of it. Respiration is quickened. The attack lasts about a minute, and terminates by flushing of the skin and copious perspiration."

Other attacks are described during her stay in hospital, some of them lasting four or five minutes, sometimes (that is, the pain) several hours. She cannot lie down while the pain is present, but on the contrary has to get up and walk about when it is very acute. When the retro-sternal pain has lasted for a considerable period it usually ends by becoming unbearably acute for a few seconds and then disappearing suddenly. At the moment of its disappearance she has the impression of some mass or organ behind the sternum suddenly shifting from left to right. During these attacks tachycardia was constantly noticed, but strangely enough I do not find exact figures recorded till December 25th last. The note says:—"Patient has had an attack this morning. The apex beat is felt and seen in the fifth space and nipple line. By auscultation the pulse rate is made out to be 260 in the minute. Patient states that during the attack

(a) Paper read before the Medical Section of the Royal Academy of Medicine, Ireland, on December 19th, 1902.

she feels her left arm to have lost sensation and power, and to be as if tightly bound up. This arm is at present colder than the right."

In subsequent attacks the pulse is noted at 240 and 230 a minute, always having to be counted from the heart beats as heard through the stethoscope.

Finally she left hospital in January of this year quite unrelieved. Digitalis, nitro-glycerine, nitrate of amyl, chloroform, purgatives, careful dieting, and many other measures had been tried in vain. It is stated that on one occasion Faradism, one pole being applied over the spine of the first dorsal vertebra and the other just below the left mastoid process, cut short an attack of pain in ten minutes. But as that attack had begun at 10 a.m., and the experiment was not tried till 5.30 p.m., and as the interrupted current failed to do any good on subsequent occasions, I am fain to believe that the application of the current almost coincided with the natural end of an attack.

Since she left hospital she has come to see me at my house, for I was anxious to follow such an interesting case, and I could not find time to interview her at her extern visits to the hospital. Before she left hospital I had put her on a mixture containing the bromides of potassium, sodium, and ammonium; but she had not seemed to derive any marked benefit from it. About May last, however, I determined to try their effect afresh, and put her on a mixture containing about fifteen grains of the mixed bromides in the dose. This quantity was taken at first three times a day, then four times, then five times, six times, and seven times; and then I lost sight of her. But about a fortnight ago she called on me to tell me that she had had no attack since June, was as well as ever, and could now work hard, and lie down on a low pillow at night instead of being propped in the half-sitting position which she has been compelled to assume for years.

I shall offer very little criticism on the preceding history. Told in this compressed form it cannot fail to suggest what was by no means evident from day to day, namely, that the attacks had an epileptiform character, and the improvement whilst taking the bromides seems to confirm that view. But the word epilepsy is no more an explanation of morbid phenomena than is "hysteria" or "nervous debility." I am still unable to decide as to the cause or origin or even the true site of the pain which my patient complained of, and which, it must be remembered, presents itself to her as the chief and original element in her trouble. I have no evidence that she suffers from any symptoms suggestive of major or minor epilepsy at any time except during the cardiac pain and racing; and I remain quite in the dark as to whether this is to be set down as a case of visceral epilepsy with very occasional cerebral extension, or as a case of central epilepsy, with cardiac convulsions as its peripheral manifestation, and cardiac pain analogous to the soreness and weariness left in the muscles after a severe fit of the ordinary type.

If we accept at all the theory of a visceral epilepsy, it must, of course, be in a very different sense from that which epilepsy usually connotes. We must take note of the more or less constant, and no doubt more or less rhythmical, functioning of most of the viscera; and the conception of epilepsy of such organs must allow of the con-

vulsion being much more slowly established, much longer sustained, and attended by far different cerebral phenomena from those associated with the ordinary *petit* or *grand mal*. Whether it is at all profitable to add *visceral epilepsy* to our swollen catalogue of diseases is no doubt open to question. If, however, it should turn out that there are cases of recurring pain and spasm referable to certain of the viscera, and not to be accounted for by other explanations, and if a certain proportion of these are benefited by the treatment which suits ordinary epilepsy, the doubt will be answered. For the present, conditions such as paroxysmal tachycardia remain inexplicable, and any hint towards an effective treatment must be welcome.

NOTE.—The patient has called to see me at the beginning of the year, and reports that she has had no recurrence of her trouble, and remains quite well.

Clinical Records.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

An Obscure Form of Anasarca of the Lower Extremities.

Under the care of W. WILLIAMS, M.D., M.R.C.P.,
Hon. Physician to the Hospital.

DURING the twenty-three or twenty-four years I have been honorary physician to this hospital, some half-dozen cases have been admitted into my beds suffering from an obscure form of anasarca of the lower extremities.

Of these cases two were women, and all of them adults under forty. In all, the dropsy had come on rapidly; it was confined to the lower extremities, there was no invasion of a serous sac. In all the cases the abdominal walls were involved, and the scrotum, in the males, distended. In one case the fluid gravitated into the left arm while it was hanging out of bed during sleep. In all the cases there was some distinct enlargement of the liver, and some, but slight, tenderness over this organ. In all other respects the patients appeared to be quite well. There was no dyspnoea or other lung trouble, and the recumbent posture was easily maintained. The heart's action in each case was that of a healthy person at rest, perfectly quiet and unembarrassed, and the valves were sound. The urine was free from albumin, and seemed to ordinary tests to be quite normal. Under these circumstances, the presence of an extreme degree of anasarca of the lower extremities in young and vigorous individuals was very unaccountable.

The histories were all the same in one respect: all the cases had for some time indulged freely in mild ale, and none of the cases had, so far as I could ascertain, accustomed themselves to spirits. I saw my first case in 1876. This was a private patient, a publican, *æt.* 45, I found him up, but with both his legs enormously distended with fluid, the skin smooth and shining; there was oedema of the abdominal walls, the scrotum was full and so was the left arm, the latter having become so while hanging out of bed the previous night. The symptoms had all of them come on during four or five days; he did not feel specially ill; he could lie down quite comfortably.

I examined the heart and lungs and found these organs quite healthy; the urine was quite normal. The liver dulness was increased and extended below the costal margin, but not much, and there was some tenderness. There was no jaundice.

In considering the case and its treatment, I came to the conclusion that the liver enlargement produced the symptoms. This enlargement was not due to any inflammatory change, but to over-distension of the organ with nutritive material derived from the grain, in which mild ale is so rich, that the enlarged liver pressed upon, or in some other way interfered with,

the circulation of the inferior cava. Yet, the fact remains, that other forms of liver enlargement fail to produce similar symptoms. Still the obstruction here affected the inferior cava alone.

He was given half a grain of calomel every night a week, followed by a saline purgative each morning. Stimulants were stopped.

The recovery was as rapid as had been the incidence of the symptoms, and this man never had a second attack. He continued to take stimulants, and soon passed from beer to spirits. He died of pulmonary tuberculosis on January 9th, 1884. There never was any cirrhosis of the liver, or any of the symptoms of this disease.

I have never known a case of cirrhosis of the liver to occur from beer drinking.

I may mention that there was no peripheral nerve trouble in this case nor in any of the others.

Transactions of Societies.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD DECEMBER 18TH, 1902.

The President, RUSHTON PARKER, Esq., B.S., F.R.C.S., in the Chair.

DR. GROSSMANN showed a case of CONGENITAL MALFORMATION OF IRIS IN BOTH EYES.

In this case the patient, an undeveloped boy, æt. 14, is subject to nervous twitchings of the head, and horizontal nystagmus and microcornea in both eyes. The right iris is represented by a narrow band, stretching across the base of the lower quadrant. In the left eye only the lower quadrant is missing. From the presence of choroido-retinitis, changes in the nasal bones and the teeth, the diagnosis must be specific intra-uterine uveitis. Dr. Grossmann also demonstrated a case of peculiar choroidal traumatism. The right eye showed two choroidal ruptures which surrounded the optic nerve on its temporal side in two concentric semicircles. Vision was lost in the corresponding portion of the field. He thought these lines of rupture clearly demonstrated the existence of lines of weakness, and pointed out the analogy between this occurrence and that of staphyloma.

LIGATURE OF AXILLARY ANEURYSM.

Mr. F. T. PAUL showed a gardener, æt. 59, whose right subclavian he had ligatured in the second part for an aneurysm of the axillary artery, extending up to and involving the third part of the subclavian. The patient had suffered from syphilis, and had been subjected to local strain of the artery. There was evidence of extensive endo-arteritis, and the vessel where ligatured was considerably diseased. Catgut sterilised in xylol was used, and was not drawn tight. The wound healed by first intention, the aneurysm filled with firm clot, and was now, two months after operation, shrinking satisfactorily.

Sir WILLIAM BANKS had seen three cases of traumatic axillary aneurysm, a disease of by no means frequent occurrence. The first case occurred in a sailmaker, and distinctly followed a strain, but the vessel might quite well have been atheromatous. Two years after successful ligature of the subclavian it was impossible to know there had been any aneurysm. In the second case degeneration of the artery was unlikely, as the patient was a young healthy man; the condition was due to a railway crush. The aneurysm had spread into the neck, and was as much subclavian as axillary. With the aid of his colleague, Mr. Paul, Sir William Banks made a strenuous attempt to ligature the first part of the left subclavian in the thorax; the pleura was a good deal injured, and the patient died from pleurisy. In the third case the aneurysm resulted from injury, produced by an attempt to reduce a dislocated shoulder. At the operation, in which he assisted Dr. Nathan Raw, the pectorals were divided and a temporary ligature placed at the highest point of the

axillary artery, the aneurysmal sac was opened, and the vessel tied above and below. Complete recovery followed. He adverted to the splendid case mentioned in the *British Medical Journal* for December 17th, 1902, by Professor Annandale, as one of the great achievements of Syme, who laid open the aneurysm, while Lister controlled the subclavian through an incision in the neck. Dr. Molyneux had discovered the aneurysm in Mr. Paul's case quite casually; it had caused no discomfort whatever. The patient had for years suffered from gout, and he thought the gouty diathesis had more to do with the case than syphilis.

The PRESIDENT had seen three cases, and in all a traumatic factor was present. Dr. PUTNAM also spoke, and Mr. PAUL replied.

Dr. BOUVERIE MACDONALD described a case of MULTIPLE RODENT ULCER.

There was no history of syphilis in the patient, a woman, æt. 45, and no history of cancer in the family. The ulcers were seven in number, situated in the left mammary region and above the left clavicle. The condition had existed untreated for two years. He had been unable to trace a record of any similar case. The case showed all stages from the initial node to the final typical crater-like ulcer. The diagnosis of rodent was based on (1) the slow growth, (2) the good health of the patient, (3) the marked tendency to heal, (4) the non-implication of the axillary glands, (5) the evidence of the microscopical sections prepared by Dr. William Anderson and others.

Mr. PAUL said the histological characters were those of glandular carcinoma, and if it was certain the disease had originated in the skin they might have been consistent with the appearances presented by some varieties of rodent ulcer. On seeing the patient, however, he had no hesitation in deciding that it was a rare form of ulcerating cancer of the breast.

Sir WM. BANKS and Dr. ANDERSON spoke, and Dr. MACDONALD replied.

Mr. EDGAR BROWNE read the conclusion of a paper on

STRABISMUS.

(continued from previous meeting) which will be found in another column.

In the discussion that followed, Mr. R. J. HAMILTON urged the earliest discovery of, and, therefore, treatment of children with an unusual degree of hypermetropia. Full correction by glasses, and operation at an early age was recommended. Stereoscopic exercises, though scientifically sound, could not in practice be carried out.

Dr. GROSSMANN said there was not the slightest doubt that Donder's explanation was perfectly correct for some cases, but for some only; hypermetropia exists, it is true, in the majority of squint cases; but also in the majority of non-squinting eyes. Squint also occurs in myopia (converging concomitant squint). It is true a new-born child does not converge correctly, but it is still more important to note that a new-born child is highly amblyopic. Vision is developed after birth, and thereupon depends the importance of the educational treatment. The relationship between accommodation and convergence is completely an acquired one in man; so also is binocular fixation. The treatment of convergent squint should be threefold: by glasses, by educational methods, and by operation. The value of the educational treatment is great only in the very young. In older patients the importance of operation for cosmetic reasons, makes the severe criticisms of Stromeyer and Dieffenbach unjustified.

Mr. RICHARD WILLIAMS could only accept Donder's theory of squint causation in a very partial degree. To him squint was essentially the result of deranged nerve impulses, and hypermetropia played only a minor part. As to the educative treatment, he thought the result nothing like commensurate with the trouble involved, and patients were mainly interested in getting their eyes "put straight."

Mr. EDGAR STEVENSON said he first became acquainted with Mr. Edgar Browne's ideas when his

house surgeon, and regarded them as heterodox. But he had lately had opportunity of studying this subject, and had been struck especially by the practical results attained. He instanced the case of a girl, *æt.* 15, whose treatment had been begun at eleven months of age, in whom the cosmetic results were perfect, besides advantages not obtainable by operation. He was convinced the views were in the main correct and the treatment the most advantageous, to the patient, however tedious and difficult it might seem.

Mr. HUGH E. JONES drew attention to the danger of operating in cases of squint when the nervous system had not become stable, or had become unstable, as in hysteria. He believed there were many cases of true amblyopia, due to imperfect development of some part of the nerve apparatus of one eye, and that no amount of training could bring the vision of such an eye to more than about six thirty-sixths.

Mr. C. S. SHEARS thought the ideal aim in the treatment of hypermetropic squint was the restoration of binocular vision; stereoscopic exercises were almost impracticable, and especially so in hospital out-patients. He always followed the teaching of his old master, Mr. Edgar Browne, and corrected the refraction at the earliest possible age. He believed the great majority of squinting eyes lost their sight because they squinted, and that great improvement in vision could be obtained by regular exercise. When the eye was amblyopic from birth no exercises would do good. Where glasses were producing no improvement an operation should be performed about the age of six or seven. In extreme cases, where advancement of the external rectus was required, there was no operation to compare with that devised by Mr. Richard Williams.

Dr. J. J. O'HAGAN, as a general practitioner, thought more attention ought to be given to eye muscle exercises, and prolonged wearing of glasses. He was opposed to early and indiscriminate operation, as he had seen some very bad results therefrom.

Mr. BICKERTON and Dr. ABRAM spoke, and Mr. BROWNE replied.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 4th, 1903.

TREATMENT OF SYPHILITIC CHANCRES

PROF. THIBERGE, in introducing the subject of syphilitic chancres, said he would divide them into genital, perigenital, and extra-genital chancres. The first needed no special remarks from him; he would confine himself to the two latter, which, although frequently observed, present sometimes a certain amount of difficulty in their diagnosis. The perigenital chancres were those to be found around the anus, the abdomen, and the inner portions of the thighs. These chancres were generally about the size of a shilling, of a rounded or elongated form. They resembled in every way those of the genital organ. The chancre of the anus was somewhat different; when it penetrated to the sphincter it took the form of a fissure, and was very difficult to examine, because it was accompanied with pain which resembled very much the ordinary fissure. Induration was always present but difficult to feel with the finger on account of the sphincter.

The chancre of the pubes was generally small and covered more or less with a crust.

The extra-genital chancres were very frequent and occupied any and every portion of the body; that of the lips was the most common. It occupied the upper or lower lip, was slightly ulcerated, and was always to be found at either side. One important characteristic of those sores was the tendency of the patient to project the swelled lip considerably. It was hardly necessary for him to allude to the existence of gan-

glions in the sub-maxillary regions, and which were pathognomonic of the malady.

The chancre of the buccal cavity was of considerable importance by reason of the difficulty of diagnosis and the errors to which one was exposed. It was not, as might be supposed, the result of abnormal coitus; but was due, on the contrary, very frequently to the ejection of saliva mixed with purulent liquid either in conversation or osculation.

Chancre of the tonsil presented a variable aspect, slightly eroded with red coloration in the centre and, the surface sprinkled with red or grey points. The sore was indurated, or rather the erosion rested on an indurated tonsil. The chancre was accompanied by a certain difficulty in deglutition, pain, and general malaise which could lead one to suppose it was a case of ordinary sore throat. The diagnosis was not consequently very easy, and many deemed it prudent to wait for the appearance of the general phenomena before giving their opinion.

Chancre of the nose and eye were rare. In women the commonest seat of the disease was the mammary region and was almost the exclusive appanage of nursing women. The sore was seated at the base of the nipple, of rounded form and of red aspect. In order to arrive at a satisfactory diagnosis it was necessary to examine the infant for hereditary syphilis and seek for initial manifestations of the infection on the nurse.

Chancre of the fingers was especially to be seen in medical men, and resulted from inoculation. That sore was frequently ignored as to its nature on account of the variety of aspects it presented. Although it could be characteristic—round, red, indurated at the base, &c., it often presented the type of a whitlow, but was particularly persisting and accompanied by considerable swelling of the ganglions in the axilla.

The prognosis was not very favourable in the case of extra-genital chancre, as the syphilis which followed had a deservedly bad reputation. It presented particular gravity, either in the immediate effects of the chancre, which had a tendency to develop and to suppurate, or in later specific manifestations. For one or other of those reasons such cases of syphilis were always grave.

As to the treatment, it was necessarily local and general. Certain authors believed that the specific treatment should not be ordered at the outset, but he was not of that opinion; on the contrary, he considered that the mercurial treatment should be instituted as soon as the nature of the affection was understood.

The local treatment should be of the simplest and least irritating kind; boric acid and vaseline or some inert powder as bismuth or dermatol. Calomel should not be used, in his opinion, under any pretence.

NO SMOKING.

The new Dean of the Faculty of Medicine has marked his assumption of the reins of office by forbidding smoking on the school premises. He points out that no other students enjoy such liberty, and he believes that in addition to being an excellent item in the cultivation of the art of self-control, it will assist students in concentrating their attention on work. The ukase, however, created such marked and noisy discontent that the restriction has so far been relaxed that smoking will still be permitted in the dissecting rooms and in the *salles* devoted to operative surgery on the dead bodies.

DR. WILLIAM SAVAGE, of Cardiff, has been appointed Medical Officer of Health of the Borough of Colchester, out of seventy applicants.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 4, 1903.

At the Laryngological Society Hr. Davidsohn showed a man who had

BILATERAL PARALYSIS OF THE POSTICUS NERVE.

as sign of commencing tabes. He had become infected four years previously. There were no disturbances of sensibility, both pupils were contracted, the left more dilated than the right; the right did not react to light, the left did so slowly. The pulse was accelerated. Oppenheim's symptom was present, viz., pain on pressure on the inner side of the sterno-cleido muscle at the level of the annular cartilage. The left vocal cord was almost immovable near the middle line, the motility of the right was diminished outwards. The speaker remarked that this form of paralysis was not rare as an early symptom of tabes; in a case reported by Sernou it had been for three years the only symptom.

The *Deutsch Med. Zeitung*, December 18th, has a reference to

TWO CASES OF PRIMARY CARCINOMA OF THE LIVER, reported by Dr. Weiss. Primary carcinoma of the liver was a rare disease, as Hausmann only met with it six times in 258 cases of cancer of the liver. Pleitner met with it ten times in 216 cases, and Eggel had only been able to collect 168 cases in all. In one of Weiss's cases there was extensive diffuse cirrhosis; the other showed no inflammatory thickening of connective tissue. As regarded the connection between the cirrhosis and the carcinoma in the first case, the writer concluded that the form was to be looked upon as the primary affection. Cancer and liver tissue were both sharply differentiated. Even in parts where hypertrophic and hyperplastic processes were extensive there was no transition stage between these and the carcinoma.

At the Society for innere Medizin, Hr. Lassan showed patients suffering from

TUBERCULOSIS OF THE SKIN.

The first case was one of severe tuberculosis varrucosa of the left arm that had existed five or six years. The patient was a worker in a light factory in Spandau, but previous to that he had been engaged in a dairy in the country, and had to look after cattle, where he had the opportunity of contracting the disease from tuberculous animals. Another case was reported where a butcher had been infected from animals suffering from *perlsucht*.

The second patient, a female, had miliary tuberculosis of the skin. At the commencement of treatment she was very much reduced, as she could take so little food owing to extensive tuberculosis of the tongue. Bacilli were present in the sputum. The tuberculous patches in the tongue were painted with balsam of Peru, which gave great relief. A visible diminution in the size of the tongue and great improvement in the general condition were brought about by injections of helol. Injections of tuberculin were not employed as it was feared that accidents might arise from oedema of the diseased tongue.

The third case was that of a woman, æt. 19, who had extensive ulcers of the leg without varices. Her husband was healthy. The painful serpiginous ulcer was at first taken for syphilitic and was treated accordingly, but without result. It was then surmised to be tuberculous, and injection of tuberculin proved successful.

The fourth case was that of a young lady with extensive deep cicatrices from former fungous tuberculosis

of the skin of the leg. She had now been cured for twelve years by injection of tuberculin.

Hr. Bohne related a case of

TRAUMATIC LATE APOPLEXY.

The patient was a man, æt. 45, who in November, 1900, had been pulled from a ladder and fallen with his head on the ground, another man falling on to him. The man did not lose consciousness, and complained only of headache. Sixty days after the injury speech became difficult, diplopia came on, and weakness of the right leg. Examination revealed no traces of former syphilis, sound heart and kidneys, and the man was not a drinker. There was blepharo-clonus of the right eye from paresis of the superior rectus muscle. Seven weeks later there was general improvement. Then came an apoplectic attack with right-sided paresis. Then there was further improvement, again followed by five apoplectic attacks. Optic retinitis then came on, with subsequent atrophy. He was then placed in an infirmary, where he remained a considerable time, and where the paralytic symptom improved. The intelligence had suffered. A connection was assumed between the accident and the disease. All conditions for assuming such a connection as recently given by Stadelmann were fulfilled in the case—a healthy man, of middle age, shock, development of the disease under the eye of the medical attendant.

At the Frei Society of Surgeons Hr. Casper spoke on what he called

KIDNEY DEATH AND KIDNEY INSUFFICIENCY.

He defined his idea of kidney death as that after extirpation of kidneys; he was of opinion that these causes of death could be avoided by giving sufficient attention to the actual functional power of the kidney. He was opposed to Israel, who had stated that in his last eighty cases he had not lost one, although he had neglected examination of the remaining kidney. He cited some cases from Israel's surgical clinique that had died from kidney insufficiency, and also a further series that had died from this cause, although Israel had attributed the deaths to other causes.

Hr. Israel observed emphatically that he had spoken only of his last eighty cases, not of earlier ones from which both himself and others had learned. Since January 1st, 1901, he had performed 104 kidney operations; he had used the phloridzine method only rarely, and had operated without regard to the results it gave. In spite of this, not one had died of renal insufficiency, although he had repeatedly operated with success in cases when testing of the renal function would have forbidden it.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 3rd, 1903.

POST-INITIAL SCLEROSIS.

At the Gesellschaft der Aerzte Lang showed a man, æt. 37, with a post-initial chancre on the chin, occurring fourteen days after the primary sore on the frenulum preputii, having been produced by himself or perhaps by a new contact. Lang thought this case amply proved his theory that there is an intermediate period between the initial sore and the general constitutional symptoms, such as the syphilitic florides on the trunk, when a new sore can be produced, having all the characteristics of the primary sore.

Shiff asked if the secondary sore in this initial period had all the manifestations of the primary sore, as he had some doubt about this.

Lang replied that he had no doubt about the case being a post-initial sore.

AORTIC STENOSIS.

Schlesinger next showed a man, *æ.t.* 44, with aortic stenosis of the isthmus and great widening of the collateral arteries from the body of the organ, particularly those towards the spine, which were distended to an enormous size. The arteries of the upper half of the body were well filled, and the left ventricle hypertrophied. Over all the valves there was a slight systolic murmur as well as in the *arcus aortæ* and along the left side of the spine posteriorly. The *aorta abdominalis* was tender, but no pulsation could be found in it; the femoral artery was slightly filled and gave a feeble wave, while the radial artery could be found distinctly but somewhat later in impulse. The development of the body was good, and from the general history the patient was able to perform heavy work without any inconvenience. There was no history of injury or inflammation, neither could any aneurysm be discovered with the Röntgen Rays.

The diagnosis was a congenital stenosis of the isthmus, or, in other words, a stenosis at the opening of the *ductus arteriosus Botalli*. This is now the fourth case of the same kind recorded by Schlesinger.

GUMMA IN THE MUSCLES.

Ehrmann next brought forward a patient, *æ.t.* 50, with a gumma in the right *latissimus dorsi* which was about the size of a man's fist. It was situated over the junction of the true and false ribs and had existed or over twenty years. Below the level of the gumma on the left side there were the remains of a pustular syphilitic in the form of an ulcer about the size of a gulden.

The Operating Theatres.

GREAT NORTHERN HOSPITAL.

SUPPURATION OF THE KNEE-JOINT.—Mr. PEYTON BEALE operated on a woman, *æ.t.* 25, who had been admitted with an inflamed pre-patellar bursa, together with intense pain in the knee-joint. She had suffered from an enlargement of the bursa for some weeks, but a few days prior to admission it had become acutely tender and had evidently suppurated. The day before admission the intense pain in the knee-joint had come on. The whole of the skin round the joint was acutely inflamed and œdematous, and the least attempt at movement in the joint caused very great pain. It was supposed that the suppurated bursa had opened into the knee-joint, probably through a small opening. The articulation was freely incised on either side of the patella, a good deal of pus being evacuated; it was then proved that the pus had found its way from the bursa into the joint by means of a small communication. The bursa itself was next freely opened in the middle line, and its cavity, together with the whole cavity of the knee-joint, was well flushed out with 1 in 40 carbolic lotion. A gauze drain was inserted into the joint through each incision, and the wounds dressed with boracic fomentations. Mr. Beale pointed out the patient was in a very bad state of health, and not in a condition to bear any prolonged operation or even lengthy anaesthesia. He said that these cases were fortunately not very common, and when they did occur they were difficult to deal with, because the knee-joint was one which could not be opened as freely as many others, excepting by dividing the *ligamentum patellæ*, and even when that was done it was still very difficult to drain the posterior part of the joint. He thought that on the whole continuous irrigation of the joint

was the best method of treatment, the limb being kept at rest on a splint or between sandbags. He had recently been trying lysoform, a preparation of formalin, in such cases. If used in a strength of 1 in 20, it was found to check suppuration very rapidly. The solution, being alkaline, forms with the pus a rather thick, tenacious,ropy fluid, so that in using it it was necessary to wash out an abscess alternately with lysoform solution and with sterilised water; the solution appears to exert no deleterious effect locally or generally.

During the next few days the patient developed a very high temperature, and the suppuration increased in spite of very free irrigation of the knee-joint; about a week after the operation the joint was very freely washed out with a 1 in 20 solution of lysoform. The effect of this was very marked, for the suppuration ceased, and the wounds were healed within a fortnight. In this case Mr. Beale said he could not use it earlier because he only received a sample about a week after the woman had been operated upon. Since then he had used it frequently for washing out acute abscesses, and found that it always checked suppuration at once.

With regard to the subsequent treatment of the case it was necessary to break down adhesions in the articulation under anaesthesia more than once. Treatment of the joint by hot air and steam after breaking down adhesions was of the greatest benefit, and in several cases of acute suppuration of the knee-joint Mr. Beale had been able to get a very fairly movable joint, so freely movable indeed as to produce no noticeable deformity in walking. He pointed out that it used to be said that in such cases amputation through the thigh should always be performed, but in these days one might be sure of obtaining some movement at any rate by means of careful after-treatment, that is, forcible movement alternating with hot air and steam during several weeks. Lysoform, he said, is a German product, and seems to be a most valuable antiseptic, its greatest value appears to be in its efficacy for sterilising skin, for it can be used pure, and as it contains glycerine and soap in addition to formalin, lather is formed when the skin is washed with it, thus removing fat and allowing the antiseptic to act upon the skin; even when used pure it produces very little, if any, roughening of the skin, much less in fact than 1 in 40 carbolic. He quoted a paper written by Professors Hewlett and Tunnicliffe (*MEDICAL PRESS*, October 29th, 1902), in which the value of lysoform as a germicide was well shown by various experiments conducted in the King's College bacteriological laboratory. Clinically Mr. Beale had found it very valuable in rapidly checking suppuration, as a skin and instrument steriliser, and as a deodorant in such cases as foul appendix abscesses and moist gangrene, in the latter cases a solution of 1 in 40 is found to annihilate the smell of moist gangrene almost instantly.

The Out-Patient Departments.

TOTTENHAM HOSPITAL.

CASES FROM THE DERMATOLOGICAL CLINIC, UNDER THE CARE OF Y. NORMAN MEACHEN, M.D., M.R.C.P. LOND. AND ED.

1.—**TINEA TONSURANS, WITH ARTIFICIALLY PRODUCED KERION.**—The patient was a boy, *æ.t.* 13, who had been suffering from ringworm of the scalp for six weeks. During the latter part of this period he had been applying a "brownish" ointment obtained from a chemist, which produced considerable irritation. When seen, there were numerous boggy, crusted patches

scattered irregularly over the scalp, pressure upon which caused a sero-purulent oozing. Some "stumpy" hairs were present in the vicinity. Dr. Meachen remarked that such a condition not infrequently resulted from the application of very strong ointments, especially when prescribed by unskilled and unqualified persons, and that the remedy, as in this case, was in consequence worse than the disease. It was doubtful whether the hair would grow again upon many of the patches, as some follicular destruction was almost inevitable in kerion, particularly when produced by irritating applications. A lotion of boracic acid was ordered with which to foment the inflamed areas, together with boracic ointment. Three weeks afterwards, the scalp presented numerous bald, smooth, atrophic places, corresponding to the previous areas of suppuration, upon which a few scattered, normal hairs were growing, but some diseased hairs were still observable in other situations, for which an ointment was ordered to be rubbed in containing 10 grs. of mercuric nitrate to the ounce of vaseline.

2.—OCCUPATION-DERMATITIS OF MIXED ORIGIN.—

The patient, a single woman, *æt.* 24, was employed in a sweet-factory, her special duty being to mix together certain proportions of chlorodyne, linseed, and liquorice into a paste with her fingers, and mould it into "cough-lozenges" of oval shape. For three weeks she had been suffering from a "breaking-out" on the hands, and when seen there were marked eczema of the squamous and cracked variety upon the palmar aspect of the fingers of both hands, the thumbs and first two fingers being most affected. Washing was very painful and contact with the lozenge mass was well-nigh unbearable. Dr. Meachen said that the origin of the dermatitis in this case was very complex, but in all probability the chief irritating factors were the morphine and the capsicum contained in the chlorodyne, especially the former, the linseed also having some share in the process. The patient said that others in the same room as herself had also had "bad hands." She was strongly advised to get different work in the factory, to use bran-water for washing the hands, and to avoid soap of any kind. A very weak lotion of creolin was prescribed, together with an ointment of equal parts of ung. zinci and ung. plumbi subacet. of the B.P., with which the hands were to be thickly anointed at night an immediately covered with thin cotton gloves. One week after this treatment the patient returned expressing herself as much benefited, and although she was not in a position to give up her work at the factory, she had been given a change of duty in mixing chocolate-creams instead of cough-lozenges.

THE officials at the Herbert Military Hospital, Woolwich, are expecting a visit from the Queen at an early date to open the new quarters for women nurses. These buildings are the outcome of the new scheme for the reorganisation of the Army Nursing Staff, under the auspices of Queen Alexandra's Imperial Military Nursing Service. Accommodation is being provided for forty additional women nurses, who will supersede male nurses, and the organisation will be on similar lines to those obtaining in large civil hospitals.

THE death is announced of Mr. Paul Quick Karbeck, M.R.C.S., L.S.A., Medical Officer of Health for Torquay, consequent upon an attack of apoplexy, which seized him when engaged in preparing a lecture a month since. Mr. Karbeck's tenure of office was marked by the most strenuous efforts to secure a pure water supply, efforts which were attended by a considerable measure of success. Mr. Karbeck, moreover, did not restrict his interests to purely professional topics, and his literary attainments gained for him great distinction. He was one of the past presidents of the Torquay Medical Society.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25 Os. 0d.; Half Page 22 10s. 0d.; Quarter Page, 21 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion, 6d. per line beyond.

"SALUS POPULI SUPREMA LEX,"

WEDNESDAY, JANUARY 7, 1903.

THE PRIZE ESSAY CONSUMPTION SANATORIUM.

In these days scientific medicine travels fast, so that no human malady can be regarded as beyond its ultimate reach. In the case of tuberculosis its patient labours have been attended by success that may be compared favourably with any triumph hitherto gained by intellectual man over the evils of his bodily environment. Its progress in that particular case presents a history that is familiar enough in the annals of medicine. First of all, tuberculosis was regarded as an incurable disease, a position which was maintained, broadly speaking, until the beginning of the nineteenth century. In the United Kingdom Carswell was one of the first to insist upon the curability of phthisis, a point which he emphatically advanced in the year 1836 on the evidence afforded by pathological anatomy. Special hospitals for consumption, established in our own country, served to confirm that view. It was not until 1882, however, that the study of tuberculosis was placed on an exact scientific basis by the announcement of Professor Koch that the disease was due to a specific pathogenic bacillus. That discovery naturally gave an immense impetus to the study of the treatment of tuberculosis from both the curative and the preventive points of view. The most successful modern therapeutic methods in dealing with this disease depend upon placing the patient in the best possible hygienic environment as regards air, food, clothing, exercise and other details of his daily life. The open-air treatment of the malady, however, was advocated by George Eodington, of Sutton Coldfield, more than forty years before Koch's discovery of the *Bacillus tuberculosis*. He shared the contumely that is commonly bestowed upon genius in advance of the age. But time has brought its meed of recognition, and the principles of Bodington are now among the commonplaces of medical

teaching. The main question nowadays is how best to carry out their administration. With the view of solving that problem, in January, 1902, a prize essay was announced for competition by his Majesty the King. The subject was the erection of a sanatorium in England for tuberculosis, to be competed for by medical men with or without the assistance of architects. Substantial prizes were offered for the three best essays, and the object of the competition was to furnish data for the erection of a sanatorium to be built by the King from a sum of money generously placed at his disposal by Sir Ernest Cassel. The first prize was subsequently awarded by an advisory committee to Dr. William Latham, in conjunction with an architect, Mr. William West. The second fell to Dr. F. J. Wethered, working with Messrs. Law and Allen, and the third to Dr. E. C. Morland, with Mr. G. Morland as architect. Honourable mention was made of Dr. P. S. Hichens, Dr. Turbon, Dr. Jane Walker, and Dr. J. P. Wills. The mass of material thus brought together is enormous, and suggestions of great value will be found in all of the essays. At the same time the main interest naturally centres in the three leading essays, which have been reproduced in their entirety in the columns of a contemporary journal. The essay that secured the first prize, namely, that of Latham and West, has been published in book form by Messrs. Baillière, Tindall and Cox. The appearance of this volume within a few days of the publication of the essay speaks well for the enterprise of modern medical publishers. In an article like the present it would clearly be out of the question to attempt anything like a detailed criticism of so important a work. The ground that is covered includes a discussion of the principles involved and their application in the erection of a sanatorium for tuberculosis. A vast number of pertinent facts are also supplied in the form of appendices. Altogether, the matter set forth in Dr. Latham's essay may be said to afford a kind of latter-day compendium of preventive medicine in relation to infectious disease. To master a book of this nature in itself constitutes, so to speak, the acquirement of a groundwork of a liberal education. There could be no more fitting monument of the humane and scientific tendencies of the age than the production of these essays in the early days of the reign of his Majesty King Edward VII. It may be confidently anticipated that the event will form a happy augury of fresh conquest over preventable disease by scientific medicine in a not distant future.

BUBONIC PLAGUE.

THOUGH it is much to be feared that we have not by any means done with the pandemic of bubonic plague which has spread over the world during the last few years, and therefore it is too early to draw a complete lesson from its manifestations, yet there are certain points which may be insisted on, that are not only of practical interest in the present, but should have bearing on our further study of the subject. In this respect the voluminous yellow book recently issued by the Local Government

Board, consisting of reports and papers by Dr. Bruce Low on the Course and Distribution of Plague during the three years 1898-1901, is particularly valuable, and all the more so, as Dr. Low is careful to refrain from theorising, while at the same time he emphasises facts which appear to be of importance as to the origin, mode of infection, and best means of checking the disease. The difficulty in collecting the mass of information here placed at our disposal must have been very great, for in spite of the Venice Convention, foreign governments are often somewhat reticent in communicating facts as to plague, while its very existence has sometimes been strenuously denied by local authorities, even when dozens of patients were dying per week. The origin of the present outbreak of plague may be dated from its appearance in Hong Kong in 1894, whither it had been conveyed from the mainland, the probability being that it has always been more or less endemic in various districts in China. In 1896 it was carried from Hong Kong to Bombay, which may be taken as the focus for its distribution, not only through India, but to the whole of the western world and the near east. Since that date plague has been epidemic in Bombay, and is so still, although since 1899 there has been a considerable decline in the number of cases. It is noteworthy that, great as has been the mortality in India from plague (403,671 in the five years 1896-1900), it has by no means vied with cholera, which has accounted for 2,148,149 deaths during the same period. In spite of this the dread of plague, probably on account of its comparative strangeness, has been out of all proportion to that of cholera. In consequence of the enormous trade between Bombay and other infected ports of India, such as Karachi, and the various home ports, it was to be expected that from time to time various cases of plague should reach England, and this in fact took place. Nevertheless it was not till the autumn of 1900 that any genuine outbreak of plague occurred in Great Britain, and in this, the so-called "Glasgow epidemic," the original infection was never discovered. It is well known that many animals, notably rats, suffer from plague, and at the time of its appearance for the first time in any centre it has usually been remarked that many rats are found to have died. That they are the common agents in carrying plague on ship-board may almost be assumed, and it is probable that the infection is carried to man by the intermediation of fleas. At the same time it is to be remembered that plague has usually been present for weeks, and often for months, before its diagnosis, and it seems in many cases to have, as if by mimicry, taken on the features of some disease, more or less endemic, in the locality. Thus it has for considerable periods been mistaken for such common diseases as influenza, enteric and malaria. For two years previous to the recognition of plague in Oporto, in 1899, it appears that medical men in that city were treating several cases of a peculiar type of typhoid fever with glandular swellings. When these same medical

men were afterwards shown cases of undoubted plague, they maintained that they were identical in nature with the disease they had been familiar with for two years, and the opinion was probably right. On account of this insidious method of gaining a foothold, which contrasts strangely with that of the other great epidemic disease cholera, medical men should exercise great caution in dealing with any peculiar disease accompanied by glandular swellings or pneumonic symptoms without obvious cause, for when plague has established itself, unless very rigorous measures are adopted, an epidemic soon passes beyond control. We are unable from Dr. Low's report to discover any facts bearing on the relative value of the different prophylactic sera, though he quotes the conclusion of the Royal Commission on Plague in India in favour of Hankine's fluid, while Yersin's serum is stated to have been of use in Oporto.

AN INTERNATIONAL PHARMACOPEIA.

THE movement in favour of an international pharmacopœia is steadily progressing, and although it cannot be said that we are as yet within measurable distance of its accomplishment, there are signs of a willingness to take the project into consideration on the part of the authorities of most important countries. The International Conference for the Unification of the Pharmacopœial Formulæ of Patent Drugs and Preparations, which was held in September last in Brussels, a report on which was laid before the General Medical Council during the recent session by Dr. MacAlister, discussed the matter in a spirit which justifies the hope that we shall ultimately come to a common agreement, at any rate in respect of the composition and strength of dangerous medicines as defined in the various national pharmacopœias. The credit of having taken the initiative belongs to the Royal Academy of Medicine of Brussels, on whose recommendation the Belgian Government drew up a scheme for the discussion. The questions at issue are unlikely to give rise to any dissensions of a political or economic order; the programme indeed is simple enough and presents no insuperable difficulties if approached in a scientific and humane spirit. It is hardly necessary to produce an array of facts to prove the inconvenience and danger which are unavoidable under the present heterogeneous system. In these days of rapid travel and close international communications it would be absurd to maintain the mediæval peculiarities which have come down to us from a past age. We have a common interest in deciding upon the best methods of preparing the more important preparations, in their standardisation and in their dosage, and we have much to gain from an interchange of views on this subject between those best qualified to criticise and suggest. The object of the Congress, it is true, did not comprise the realisation of an international pharmacopœia, its deliberations being restricted to the desirability of bringing about uniformity in respect of "heroic" medicaments, by which we understand drugs and

preparations possessed of active physiological properties. The importance of the subject is derived not only from the immense convenience to travellers and residents abroad of being able to obtain medicines anywhere and everywhere with the assurance that they correspond exactly to the original prescription but also that it would render more intelligible descriptions of new methods of treatment. There are, moreover, a number of countries which do not possess a national pharmacopœia or even a school of medicine, and it must be admitted that the pharmacists in such countries have a difficult task in deciding what particular preparations are intended. The first step is to select the drugs and preparations which urgently call for international standardisation; secondly, to determine the best forms in which they should be prepared and administered; and, lastly, to fix the proportion of active principles which they should contain. An international committee has been formed, with correspondents in each country represented at the Congress, so as to ensure the means of intercommunication. It is satisfactory to record that the conclusions reached were agreed to unanimously, and they are to be recommended to the respective Governments for adoption and incorporation at the next revision of their respective pharmacopœias.

Notes on Current Topics.

An Important Decision.

IT may be within the recollection of our readers that some months since a disagreement arose between the Ballachulish Slate Quarries Company and Dr. Lachlan Grant, their medical officer, consequent upon which the latter was dismissed. The men, however, strongly resented the action of the directors, and as the latter declined to yield to their wishes they formed a medical committee, and reserved to themselves the right of appointing their own medical officer, giving due notice of their intention. The company, however, took action against Dr. Grant under their agreement to restrain him from continuing to practise in the neighbourhood, and Lord Kyllachy has now delivered judgment in the company's favour, with costs against Dr. Grant. This judgment ought not to be allowed to pass unchallenged, for it would create a very unfortunate precedent. It is monstrous that a manufacturing company should have it in their power to force a contract on a registered medical practitioner obliging him to cease practising in a district at the discretion of the company, that is to say, as soon as the company think fit to determine his engagement. In this instance the arrangement between the employers and the workmen in respect of medical attendance had actually fallen through, and the men had appointed Dr. Grant to be their medical officer in virtue of the powers which they had formally resumed. His Lordship held, however, that the company were justified in making and enforcing the contract although it had virtually

become *ultra vires*, but we venture to think that this view is one which would not be upheld on appeal, and for this reason it is much to be desired that a movement should be started to enable Dr. Grant to carry the matter into a higher court.

The New Local Government Act.

THERE are some clauses in the New Local Government Act which should do much to facilitate the working of the Medical Charities Act, and as we read them we cannot avoid regretting that the Government did not see their way to making pensions to Union medical officers compulsory. The fear that a clause embodying this act of simple justice to a hard-worked body of educated men was disputatious and might possibly wreck the Bill in the Commons was groundless. All the members would bear testimony to the way in which the arduous and dangerous duties of the Poor-law medical officer are performed; and we believe their support would have been cheerfully given to such a measure of justice. The new Act has, however, improved the position of the medical officer in that during his vacation, which is taken for granted, the L.G. Board will pay half the salary of his substitute, and it allows of a superannuation being granted to the medical officer of health of an urban district. Clause 5, dealing with vacation, removes all excuse for restricting the salaries of substitutes to less than £4 4s., a sum which is generally recognised as fair; and the few pounds extra received under Clause 10 will be a welcome addition to an allowance which was never large. The very fact that Mr. Wyndham embodies the clauses is pleasant evidence that he is alive to the more glaring hardships of the conditions under which the Union medical officers work. In the public interest the removal of the injustices that press on the medical officers is advisable. When the service is made popular the local bodies will have candidates for Union appointments from the picked men of the medical profession. When it is possible to secure a competence at home, with the certainty of a decent superannuation allowance when incapacitated by sickness or old age, few men will care to go afield for employment.

What is an Accident?

UNEXPECTED difficulties have cropped up in the application of the Workmen's Compensation Act, especially in regard to the definition of what constitutes an accident. County Court judges have construed the liability of employers very liberally; so liberally indeed that it was fast becoming almost impossible to establish any line of demarcation between an accident and an illness coming on while at work. In a case recently adjudicated upon at Newcastle-on-Tyne the "accident" alleged was rupture of the aortic valves attributed to exertion in the manipulation of a heavy hammer. It was not disputed that the rupture took place while the man was engaged in this work, and his previous health appears to have been good, apart from some

trouble arising in connection with a perineal abscess. It is obvious, however, that there must have been some pre-existing weakness of the valves, or they would not have given way under a strain which was not in excess of that to which the man was accustomed. The judge, therefore, found that the necessary "fortuitous and unexpected" element was wanting and dismissed the application. In a sense this is fortunate, since, had it been otherwise, hæmatemesis or hæmoptysis occurring at work would also establish a claim to compensation, and a wholly unjustifiable scope would have been given to a highly beneficent Act. The recognition of the difference between an accident, properly so called, and mere physical depreciation is by no means to the disadvantage of workmen, for it renders it possible for employers to continue to give employment to men who are suffering from disease not severe enough to disable them for work, but from one rendering them more susceptible than others to the effects of hard work or sudden effort. There are many moot points in this connection which still await solution, and this, unfortunately, can only be arrived at by the cumbersome and costly method of judicial decision.

Out-Patient Clinics.

THE out-patient departments of hospitals provide a rich field of clinical observation, the more valuable because the nature of the ailments dealt with there differs in many respects from that of in-patients. We propose in future to devote space to observations culled from out-patient clinics, with special attention to the remedial measures adopted, and we shall welcome contributions from such of our readers as are in a position to provide us with material from this source. Out-patient practice more nearly approximates the conditions of general practice than does the treatment of in-patients. The observer meets there the thousand and one ailments which do not lend themselves to any particular morbid classification, but the treatment whereof constitutes a very important part of general practice. We publish the first instalment in the present issue, and we shall do our best to restrict this department to matter likely to prove interesting and instructive to practitioners generally.

Professor Lorenz and the Daily Press.

IN taking leave of Professor Lorenz the *Journal of the American Medical Association* deprecates any blame being placed on his shoulders for the doings of the "ubiquitous and pestiferous newspaper reporter." Our contemporary describes the Professor as "a charming character and gentlemanly scholar," who leaves behind him "many pleasant memories of a genial gentleman and a master," so that there really remains nothing for us to add, our vocabulary of eulogy not enabling us to soar above these giddy heights. Moreover, we shall shortly have an opportunity of forming an opinion for ourselves, since the Professor is now on his way to England. In discussing the advantages

and drawbacks of the bloodless operation with which Professor Lorenz' name is connected, it is pointed out that this operation is by no means "safe and harmless," as has been asserted by its partisans. Fractures of the femur and separation of the upper epiphysis have occurred repeatedly, as well as laceration of the sciatic nerves and vessels, giving rise to paralysis and gangrene. In one case, in which Professor Lorenz himself operated, complete laceration of the perineum, extending from the vagina into the rectum, was caused. These, however, may fairly be classed as accidents unavoidable in a small proportion of cases whenever a method of treatment entailing the direct application of violence is resorted to.

Coroners and Post-Mortems.

WE can quite believe, as suggested by Mr. Troutbeck, the coroner for Westminster, that the knowledge of there being an official pathologist has had the effect of bringing about an improvement in the manner of carrying out post-mortem examinations. The criticisms which we have thought necessary to make concerning the appointment of Dr. Freyberger were not directed against the principle, since it is one for which we have contended for many years. They were, in fact, directed only against the irregular way in which the appointment was made and against the exclusion of candidates of British nationality. The post is one of such importance, and involves such weighty responsibilities, that every inducement should have been offered to men of the highest repute in this department to undertake the duties of the post. Had this course been adopted no ill-feeling would have arisen, but the matter is not likely to be allowed to rest where it is, and possibly when the attention of the London County Council is called to the feeling in the profession the grievance complained of may be righted.

Medical Education in Poland.

JUDGING from the details which have come to light concerning the early career of Klosowski, *alias* Chapman, who stands charged with three murders by means of tartar emetic, the practice of medicine in Poland is not yet completely dissevered from the calling of the barber. It is stated that he obtained the diploma of barber-surgeon, and, later, applied to be raised to a higher status, apparently without success. This fact gives a fair idea of the progress of civilisation in Poland, although in all probability the status of barber-surgeon there stood on much the same footing as the *officier de santé* in France, a grade which was to a great extent abolished some years ago. Its persistence even at the present time is due simply to the fact that great difficulty is experienced in recruiting the ranks of the country doctor in the French provinces, and on the principle that half a loaf is better than none, *officiers de santé* are still permitted to practise in certain districts. A knowledge of toxicology is apt to be dangerous, unless associated with the

responsibility which comes of a recognised social status.

American Anti-Kissing Leagues.

ALL sensible people will endorse the protest uttered by some of our contemporaries across the ocean against the ridicule likely to be brought upon sanitary legislation by the foolish anti-kissing campaign upon which several States have entered. In Virginia the proposal is to enact that kissing be permitted only on the certificate of the family physician, and unauthorised kissing by any one with weak lungs or any contagious disease is to be made a misdemeanour punishable by fine. The practice may be unsanitary, though this is by [no means well established, and the current number of the *Polyclinic* contains, as if in anticipation, a very peremptory note on the subject. Discussing the assertion contained in the "Twentieth Century of Medicine" that kissing represents one of the commonest modes of specific contagion, the Editor remarks that lesions on the lips are not only extremely rare, in English practice at any rate, but that in all probability a very infinitesimal proportion of such lesions result from kissing. Advantage is taken of the opportunity to point out that leprosy cannot be so transmitted. Melancholia and broken heart seem to be really the only disorder, likely to accrue from the time-honoured practice. Sanitary or not, punishable or not, the custom is unlikely to die out, and will certainly die hard. A little risk may only give additional zest thereto. As one contemporary observes, such legislation, if proposed in good faith, is unwise because futile, and if not in good faith it is unworthy trifling.

Ethyl Chloride Narcosis.

IN recent years the well-known trinity of anæsthetics—ether, chloroform, nitrous oxide—is becoming considerably extended, and among the strongest claimants for a place in the anæsthetist's favour is ethyl chloride. It is easily administered, requiring no cumbersome apparatus, and the time required for getting a patient "under" is short, varying from a few seconds in infants to three minutes in adults. During narcosis the colour is natural and there is fair relaxation of the muscles. Awakening is rapid and complete, and there are rarely any unpleasant after-effects. The only danger is from interference with respiration, and this is due either to falling back of the tongue or to carelessness in not administering enough air. In either case untoward symptoms are easily relieved. The fatalities are very few, standing relatively in a scale between those due to gas and those to ether. It is not suitable for prolonged operations. Consequently for comfort and safety ethyl chloride is a strong rival to gas, while for convenience in ambulatory practice it is easily ahead, not requiring the heavy and cumbersome apparatus required by the other. One serious drawback however, remains to be mentioned. Dr. Ware, of New York, who has published a

record of 1,000 personally-conducted cases of its use (*Journal of the American Medical Association*, November 8th), and is warm in its praise, states that he estimates that in ninety-five per cent. of his cases an absolutely satisfactory anæsthesia was obtained. In other words, in something under five per cent. the anæsthetic failed. There are few incidents more unpleasant to an anæsthetist than to have to change his anæsthetic after starting, and unless ethyl chloride can show a somewhat better record than this, we are afraid it will not yet win popular favour. It should be added that it is very necessary to insist on getting the pure drug, as some of the impurities commonly associated with it are directly poisonous.

Tuberculosis in Lunatic Asylums.

ALTHOUGH it cannot cause surprise that the inmates of asylums for the insane should prove very amenable to tuberculous infection, it may fairly be asked whether everything possible is done to protect these unhappy sufferers from the disease. The statutory requirements in the matter of ventilation and air space fall far short of the teachings of present-day therapeutics in regard to tuberculosis. The first precaution would be the isolation of all patients recognised to be suffering from pulmonary tuberculosis, and the next step would be to give these sufferers the advantage of the open-air treatment. When this has been done we may be asked to consider the propriety of introducing the open-air mode of life for the general body of the insane as a prophylactic measure. The depraved vitality and unhygienic habits of the insane are additional reasons for taking extraordinary precautions, since they entail unusual proclivity to infection. Prisons, it is to be feared, also offer very favourable conditions for the development of tuberculous disease, and in this connection it is interesting to note that a practical demonstration of the remarkable results that may be achieved by the rational treatment of consumptive insane convicts has recently been afforded in the New York State prisons. Consequent on the removal of all prisoners afflicted with consumption to the mountains, a reduction of the tuberculous mortality, estimated at upwards of 70 per cent., has been observed during the last five years.

Operation for Perforated Typhoid Ulcer.

It is but a few years ago since a case in which a perforated typhoid ulcer was regarded as necessarily hopeless. As abdominal surgery advanced, suggestions were made that an attempt should be made to reach the ulcer by laparotomy and suture, but for some time the procedure was by many regarded as futile. However, we have now come to see that it is the duty of the surgeon in all such cases to operate immediately, since such operation gives the patient his only chance of life. As much of the success of the procedure depends on the earliness of operation after perforation, it is natural that in a few cases mistakes have been made and the operation done without discovering

the presence of a perforation; but it is unusual for any harm to result to the patient. In opening the abdomen the lateral incision is preferable, since the perforation is usually situated near the ilio-cæcal junction, and it can thus be reached with less disturbance of the intestines, and consequently less chance of general infection than from the median line. Mr. Shepherd, of Montreal, who has recently published three successful cases (*Edinburgh Medical Journal*, December), advises that it is always well to see that there are no other ulcers about to perforate. If any such are found, the covering peritoneum should be turned in over them. The other points emphasised by Mr. Shepherd are earliness and rapidity in operation.

Knighthood for Mr. C. B. Ball, F.R.C.S.

HIS Excellency the Lord Lieutenant has been pleased to intimate his intention of conferring a knighthood upon Mr. C. B. Ball. Mr. Ball is well known for his writings on diseases of the rectum, and other contributions to medical literature. He is Regius Professor of Surgery in the University of Dublin, and is attached to Sir P. Duns' Hospital. During the past year he delivered the Lane Lectures at San Francisco. It is probable that the immediate cause of Mr. Ball's honour is to be found in the extremely successful operation he performed upon Lady Dudley during the course of her recent serious illness, but apart from that his professional attainments and high reputation make him a worthy recipient of such a distinction.

The University of London and Endowment Appeals.

A TIMELY letter of remonstrance and warning has been recently issued by Mr. H. T. Butlin, Dean of the University of London, with regard to the appeals for endowment that are being made by various constituent colleges of the new University. There appear to be abundant grounds for his contention that such appeals will weaken the hands of the University when their time comes to ask the public for support. When is a university not a university? is a question that suggests itself in this connection. The answer would clearly be, When it is made up of constituent colleges which regard their individual interests as paramount. Most candid persons acquainted with the facts of the case will agree with Mr. Butlin that if the colleges pursue their present policy it will be impossible for the public to differentiate between the university appeal and the appeals of its separate colleges. In the latter case, he remarks, the University of London might just as well have remained what it was three years ago—an examining body. It certainly looks as if the constituent colleges had not grasped the central principle of community of interests and of action that must be at the root of success in the formation and the administration of a great university. Experience has shown in matters other than educational that Londoners are apt to deal parochially with many things of great importance to the community.

Smallpox in the Provinces.

So far smallpox has shown no sign of resuming its onslaught on London, but numerous more or less circumscribed outbreaks are reported from various parts of the country. In Liverpool there are upwards of two hundred cases, in Sheffield about thirty, while Rotherham, Leeds, Salford, Bradford, Stockport, Oldham, Wigan, Bolton, Birmingham, and their respective districts each contain patients suffering from the disease. The difficulty of securing immediate diagnosis and prompt isolation of the sufferers is necessarily much greater in the provinces than in the metropolis; hence it is extremely probable that these local outbreaks will extend during the winter, constituting in the aggregate a widespread epidemic. This will be a useful object lesson for our legislators when they are called upon to discuss future preventive measures.

Intra-Cardiac Injections.

THE daring procedures of the modern surgeon are well illustrated by the growing familiarity of the title, "surgery of the heart," a special branch of his work that now stands on a well-recognised footing. Tapping the pericardial cavity and suture of the muscular walls of the heart have nowadays become mere commonplace operations. It has even been proposed to undertake surgical means of remedying some of the more marked valvular defects, but the matter has not hitherto been brought within the domain of practical surgery. A new method of stimulating the heart's action has been recently introduced by a medical man in Chicago. In cases of heart failure his plan is to inject a saline solution into the cardiac cavity by means of a hollow gold needle, which is introduced through the walls of the chest. In some cases it would clearly be rational to assume on *a priori* grounds that direct cardiac stimulation produced in this way might have a beneficial effect in tiding a patient over a dangerous period of heart failure. It seems likely that fluid injected in this way would be more efficacious than when passed into the circulation by way of the veins. Moreover, in some conditions it is possible that fluids from the veins might not reach the heart quickly enough or in sufficient bulk to be of service. The plan appears to be a distinct advance upon the old-fashioned and sometimes valuable method of stimulating a failing heart by puncture with a simple needle.

The Danger of Artificial Teeth.

DURING the past few weeks there has been quite an epidemic of deaths due to the swallowing of artificial teeth. This accident almost invariably takes place during the night, while the unfortunate wearer is asleep. The obvious remedy is prevention by adopting the simple rule that artificial teeth be removed every night on going to bed. There is the further consideration that it is only by such removal that thorough cleansing and disinfection of the plates can be secured. With regard to the surgical treatment of cases of accidental swallowing of this class of foreign bodies, invaluable aid has been afforded by the Röntgen ray methods of diagnosis. In this way the surgeon

is not only led to the exact localisation of the missing teeth in gullet or stomach, but he may also sometimes be enabled by means of the fluorescent screen to direct the movements of his pharyngeal snares during actual operation.

Popular Fallacies about the Oyster.

THE maxim which teaches us that a little knowledge is a dangerous thing certainly applies somewhat forcibly to the popular view of the prevention of oyster typhoid. A correspondent to a London newspaper last week, commenting upon the recent outbreak of oyster-typhoid on the South Coast, said that oysters could be fattened up and at the same time purified of noxious germs by keeping them for a few days in oatmeal and fresh water. The so-called "fattening," as most of our readers know, is simply a form of dropsy resulting from imbibition of the fresh water. The oatmeal has probably not the remotest action in nourishing the oyster; at any rate, it is absolutely unlike any form of nutrient material furnished by Nature to that bivalve in its natural haunts. As regards the destruction of typhoid bacilli, it has been shown that such organisms will live in the tissues of the oyster after many weeks' exposure in pure fresh water. The only efficient method of prevention of oyster typhoid lies in the purification of the oyster beds and ponds from sewage matter.

The Health of the Bench.

LAST year the State Legislature of Pennsylvania passed a law authorising the appointment of medical commissioners to inquire into the mental and physical health of the judges, and it is stated that several commissions have already been appointed with this object in view. The entire judicial list will be gone through, and the fact that a judge has not been able to perform his judicial functions for twelve months or more on account of ill-health will be held to justify the issue of a commission. Everyone can probably call to mind instances in which such a commission would have rendered signal service in our own courts, and it is a lapsus in our judicial organisation that it should be possible for an aged judge to outlive his acumen and perpetrate scandals which in the long run determine his enforced retirement. The public form their opinion of the physical health of a judge by the frequency of his absence from the bench, and his mental health by his utterances and decisions when he is present. This simple rule-of-thumb method is open to the objection that a judge, who is physically or intellectually infirm, may retain his judicial functions long after his retirement has become desirable in view of the onerous and responsible nature of his duties. An automatic rule which would provide for a medical report under certain specified conditions would save a lot of trouble, and would tend to maintain the standard of judicial work. We cannot flatter ourselves that any such reform is likely to be introduced in the near future, because various weighty constitutional points would have to be solved before it could take effect. Even in Pennsylvania it is asserted by

eminent legal authorities that compulsory retirement for reasons of health could not be enforced under the constitution, but we are concerned only with the medical aspects of the question and not with the constitutional problems which are beyond our competence.

The Revival of the "Index Medicus."

We learn from our contemporary, *American Medicine*, that the invaluable work of reference, the "Index Medicus," which had ceased to exist, owing to lack of sufficient pecuniary support, is to be revived, thanks to the fact that two of its representative men are members of the Board of Trustees of the Carnegie Institution. Ten thousand dollars a year has been voted for the work, and the subscription price has been placed at five dollars. The work will be under the literary charge of Dr. Fletcher, of the Army Medical Museum. We note that no provision has been made for filling up the gap left by the interregnum, but we cannot believe that this magnificent work will be allowed to be spoiled for want of the proverbial half-pennyworth of tar, or rather ink. We are all interested in maintaining the continuity of the compilation, and we hope to hear soon that some way has been devised of remedying the lapsus.

PERSONAL.

MAJOR HEUSTON, C.M.C., has been appointed medical officer to the Royal Hibernian School, Dublin.

DR. CHARLES PORTER, of the Public Health Hospital, Leith, has been appointed Demonstrator in Bacteriology at the Sheffield University College.

DR. LORENZ, of Vienna, whose name is well-known in connection with the bloodless orthopædic method, sailed from New York on December 31st for England.

SIR JOHN WILLIAMS, Bart., has been invested by the King with the insignia of Knight Commander of the Royal Victorian Order in connection with the recent birth of a son to the Princess of Wales.

DR. S. W. FOSTER, of Barrow, was thrown from his horse on Christmas Day and sustained serious injury. Dr. Foster was trying to accustom a new horse to a motor car, but he lost control over the animal and fell upon his head. He is still in a very precarious state.

DR. W. A. MURRAY, Colonial Surgeon of the Gold Coast, has been appointed Deputy Principal Medical Officer of that colony, while Dr. Derwent H. R. Waldron and Dr. P. J. Garland, who formerly occupied the offices of senior assistant colonial surgeons, will in future be designated Senior Medical Officers of the Gold Coast Colony.

THE gold medal founded by the late Sir Gilbert Blane, Bart., to be given biennially, has been awarded by the Medical Director-General of the Navy and the Presidents of the Royal College of Physicians and the Royal College of Surgeons to Surgeon C. W. L. Bunton, M.B., R.N.; for his *Journal of H.M.S. Forle*, 1901, and to Staff-Surgeon J. Falconer Hall, M.B.

R.N., for his *Journal of H.M. Naval Brigade in North China*, 1900.

SIR WILLIAM WILSON, who has been commissioned to prepare a report on the medical services during the late campaign in South Africa, was Principal Medical Officer in the Transvaal for two years during the war. He is an Irishman, and has been over thirty years in the Army Medical Service. He served through the Afghan War, and afterwards did good work in Egypt in the 1882-84 campaign, getting special mention for his heroism at El Teb and Tamai. He has been under the hottest fires on several occasions, but has always escaped untouched.

In the list of honours conferred in connection with the Coronation Durbar at Delhi on New Year's Day we find the names of numerous members of the medical profession, viz., Surgeon-General William Roe Hooper, C.S.I., Indian Medical Service (Retired), who succeeded Sir Joseph Fayrer as President of the Medical Board at the India Office in 1895, has been created K.C.S.I. Surgeon-General Benjamin Franklin, C.I.E., Director-General of the Indian Medical Service and Sanitary Commissioner with the Government of India has been created K.C.I.E. Lieutenant-Colonel Gerald Bomford, M.D., Indian Medical Service, Principal of the Medical College, Calcutta, and Major Alfred William Alcock, M.B., F.R.S., Indian Medical Service, Superintendent of the Indian Museum, have been created C.I.E. The Kaisar-i-Hind medal for public service in India of the First Class, has been conferred on Lieutenant-Colonel Robert William Steele-Lyons, M.D., Indian Medical Service, Civil Surgeon and Superintendent of the Lunatic Asylum, Dharwar, Bombay Presidency, and upon Major David Semple, M.D., R.A.M.C., Director of the Pasteur Institute, Kasauli. The honour of knighthood has been conferred on George Watt, M.B., C.M.Glasg., C.I.E., Reporter on Economic Products to the Government of India and Officer in Charge of the Economic and Art Section of the Indian Museum, Calcutta, to whose work at the Exhibition of Indian Art at Delhi Lord Curzon referred in his speech at the opening of the exhibition. Sir George Watt, was appointed Professor of Botany in the Calcutta University in 1873, and in 1884 was made Scientific Assistant Secretary to the Supreme Government of India, and was elected President of the Pharmacological Section of the Indian Medical Congress in 1894.

Special Correspondence.

[We do not hold ourselves responsible for the opinions or correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND.—In late years a considerable number of charges of malpraxis or negligence in treatment have been brought against both medical men and dentists in Scotland, and although, speaking from memory, the pursuer has almost invariably failed to prove his case, and the judge and jury have in not a few instances clearly shown on which side their sympathies lay, still these actions, taken, as many of them are, to the Court of Session, involve the practitioner concerned in no little expense (seeing that the pursuers are rarely able to bear the costs), in much mental worry, and, unfortunately and almost inevitably, in a certain loss of reputation. The protection which membership of the Medical Defence Union of England affords to practitioners, and the deterring effect which the knowledge that a suit will be defended by the Union exerts on persons disposed to put forward baseless and

even unscrupulous claims, are sufficient to justify the existence of such bodies, while the fundamental differences between Scottish and English law and judicial procedures seem an adequate reason for the foundation of a purely Scotch Union. If any further justification were required it will be found in the list of office bearers, many of whom are men holding the highest positions in Scotland, and who, themselves practically immune from any such risks as have been indicated, are yet willing to assist their less fortunately placed brethren.

The presidents are Professors Simpson, Edinburgh; Stephenson, Aberdeen; Kynoch, Dundee; and Dr. Finlayson, Glasgow. Among the vice-presidents are Drs. Afflick, Berry Hart, and Murdoch Brown, Edinburgh; McCall Anderson, Gemmel, Lindsay Stephen, and Renton, Glasgow; Gordon, Aberdeen; Greig Dundee, as well as representatives of most of the more important provincial towns.

It is proposed to divide Scotland into four districts, each presided over by a council not exceeding twelve members. The Union will defend actions and claims against members, in approved cases, will institute proceedings on behalf of members for vindication of character, &c.; will advise in all legal difficulties arising in the practice of their professions; will act as arbitrators in disputes between members; and will consider legislative proposals affecting the interests of the profession. The subscription is 10s. per annum, and the utmost liability of any member for subscriptions, or in the event of winding-up, is £1. The Union may be heartily commended to all practising medicine or dentistry in Scotland.

Correspondence.

THE NEW SYDENHAM SOCIETY'S CLINICAL ATLAS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—You have repeatedly accorded to the Society which I represent the valuable privilege of addressing its members and others in your pages, and I am emboldened by past favours to solicit another.

The Council of the New Sydenham Society is desirous to place before the profession a statement as to what has been done and what is in progress in respect to its great undertaking to publish a Clinical Atlas of Medicine, Surgery, and Pathology, and all allied branches of professional knowledge. The decision to undertake such an Atlas was arrived at, after much deliberation, more than two years ago, and as the first year of its issue is about to be completed, we are now in a position which enables us to report as to what is likely to be accomplished.

In the first place the Council has had reason to congratulate itself in three separate directions. The number of subscribers, although much below what it is hoped may be obtained, is yet adequate; the cost of the work proves to be much less than was expected; and the supply of material is abundant. In the next place the Council feels that it is due to the Society's members to offer some explanation of what may appear like unpunctuality. We are only just about to conclude the issue of the series for 1901, and to commence that for 1902. Thus it may be said that we are a twelvemonth behindhand. No one, however, who will give the slightest thought to what the production of such a work as this means will feel any surprise at this. Our plates take a long time in passing through the artist's hands, and to hurry is to spoil. Many months also were consumed in inquiries as to whether the work would receive the support of the profession, and it was, of course, impossible to make preparation until a decision was arrived at. We are engaged not on the reproduction of any existing work, but in the publication of an original work of very large dimensions, and involving the collection of an immense amount of material, a large part of which now sees the light for the first time.

The fact just alluded to must stand as the explanation not only of a certain amount of delay in issue, but also of some want of systematic arrangement which will become apparent. Any attempt at finality in such arrangement would be to the injury of our work. New illustrations may be supplied late which it would be a great pity to exclude, and unforeseen impediments may be encountered in the production of any one fasciculus. There is but little room for automatism in the compilation of such a work as ours, and as the foremost aim of those engaged upon it will be to make it useful as a clinical record of all that is susceptible of pictorial illustration in reference to disease, some latitude must be asked for in the matter of arrangement. We shall do our utmost to study the convenience of the reader, but shall not sacrifice his real interests by a too rigid endeavour to adhere to a cut-and-dried programme. He may now and then encounter supplementary plates, or find a topic he had thought concluded again referred to. It must be remembered also, in reference to the selection of subjects, that our Atlas is an international one, and is not intended exclusively for the home profession.

The issue of works for the year 1901 will be completed in a few days by the publication of a double fasciculus, illustrating "Xanthelasma and Xanthoma as symptoms of functional or Organic Disease of the Liver." When our members for that year receive this fasciculus they will have had for their guinea a printed volume (Von Limbeck's "Treatise on the Clinical Pathology of the Blood," translated by Dr. Arthur Latham) and four fasciculi of the Atlas, which contain a total of twenty-two coloured and twenty-one uncoloured plates. Thus considerably more than was promised has been accomplished, for the Council's undertaking did not go beyond the issue of four fasciculi of eight plates each, and the addition of a printed volume was only conditional on financial success. What makes this result satisfactory is the fact that it has been attained with a comparatively small list of members. Now that our year's work is before the profession we may legitimately hope that our list will rapidly increase, and if it does so we shall be able to afford much more. Without making any sort of promise I may say that I am sanguine that instead of four we may be able to afford eight fasciculi a year, or their equivalent in an increased number of plates in each. If this can be done the Atlas will rapidly develop, and will be likely to attract still further additions to our members' list. However this may be, it is certain to become by far the largest and most comprehensive work of its class ever attempted.

In order to attain the results just alluded to, all that is necessary is that our members generally should bestir themselves. They have their own interests in their own hands. In the hope of giving a fillip to zeal in this matter the Council has decided to accord a small privilege in compensation for trouble taken. It will issue to all who pay in one sum the subscriptions of five members for any one year six copies of the fasciculi issued for that year, with also any printed volume which may have been added. This privilege will be accorded not only to local secretaries but to all members of the profession. As the stones from which the plates are printed will have to be cleaned off very shortly, and no new edition is in the least degree probable, it is desirable that those who wish to secure the work should apply early.

In conclusion, I have but to state that the issue of the Atlas (in its clinical form) began with the year 1901, and that new subscribers should at once forward their subscriptions for that year and for 1902. If it is wished to save trouble the subscriptions for 1903 may also be added. Our agent is Mr. H. K. Lewis 136, Gower Street, W.C.

I am, Sir, yours truly,

JONATHAN HUTCHINSON

General Secretary (Hon.) to the
New Sydenham Society,

15, Old Cavendish Square, London, W.,
January 1st, 1903.

OBSTRUCTIVE DYSMENORRHOEA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Some points in Dr. Duke's letter call for comment. I have not published a paper in the *British Medical Journal*. An abstract of a paper has appeared there, but the paper is not yet published. I gave Dr. Duke volume and page of my authority for the statement that many deaths have occurred from intra-uterine stems

Dr. Duke says that his stem is flexible, hollow, self-retaining, and shorter than the uterus. Some thirty years ago the late Dr. Greenhalgh recommended an intra-uterine stem having all these properties, and I know of a case (not, I am happy to say, in my own practice) in which this stem caused death.

I think that Dr. Duke and I cannot mean the same thing when we speak of endometritis. What I call endometritis is exceedingly rare in young women with dysmenorrhœa. I am, Sir, yours truly,

London, W., January 5th, 1903. G. E. HERMAN.

Literature.

GARRIGUES ON MIDWIFERY. (a)

WE confess that we lay down Dr. Garrigues' work with a feeling of disappointment. It is a large book of close on 900 pages, but the subject is not viewed from the standpoint from which we consider it ought to be. If anyone takes up the book in the hope that he is going to ransack the very latest work on obstetrics, his disillusionment will start from the very first pages—from the preface, in fact. "During the last twenty-five years only four really great improvements have been made—antiseptics, with its off-spring asepsis, the axis traction forceps, the improved Cæsarean section, and the revival of symphyseotomy." Is this really the case, and have not more important advances been made in modern midwifery than the two last on the list—more important in that they have conferred a greater benefit on a larger number of women? The improved Cæsarean section is a most valuable operation, but how frequently is it required? The revival of symphyseotomy may save us from having to test the advantages of the improved Cæsarean section, but, again, how often is it required? Surely there are other improvements which are, so to speak, of every-day value. The last twenty-five years have served to show the importance and the possibility of replacing internal manipulations by external manipulations. Abdominal palpation has to a considerable extent replaced vaginal examination; external version has in many cases replaced internal version; and the third stage of labour is managed entirely by external manipulations. Again, the treatment of the hæmorrhages of pregnancy has been placed on a rational basis, and the mortalities of by-gone days of 50 to 60 per cent. in ante-partum hæmorrhages have been reduced to from 3 to 5 per cent. Further, the necessity for ante- and post-partum vaginal douching has been disproved, and its danger, when carelessly administered, demonstrated. Are not any of these advantages greater than the last two on Dr. Garrigues' list?

A little further on in the preface we read that the book is intended to be a text-book and not a work of reference, and that for this reason all names of authorities are omitted as being matters which "only show the reading of the author, and embarrass the student." The author's own writings are, it is true, referred to but "only as vouchers of his right to take the magisterial tone used in the text." The exclusion of authorities and the use of an authoritative tone are to be commended in a small hand-book. Where, however, a

(a) "A Text-Book on the Science and Art of Obstetrics." By H. J. Garrigues, A.M., M.D., Consulting Surgeon to the New York Maternity Hospital; Professor of Obstetrics in the Post Graduate School (retired), Professor of Gynecology and Obstetrics in the School for Clinical Medicine (retired), etc., etc. Pp. xxx, and 844. With 504 illustrations. Philadelphia and London: Lippincott and Co., 1902. Price 25s. net.

work reaches the proportions of 900 pages, a little more is expected of it.

We now come to the book itself, prejudiced, we confess—by the preface. The fifth chapter of Dr. Garrigues' work treats in an unnecessary manner of the subject of copulation. We consider the book would be improved by its omission. The chapter on hæmorrhages is poor, and the treatment recommended does not appear to be modern in tone. We are told that, in placenta prævia, when the fœtus is dead, and even after hæmorrhages have occurred, we should try to continue pregnancy until term is reached in the hope that "the placenta will atrophy, and the danger of bleeding during and after labour be much lessened." Is Dr. Garrigues the inventor of this remarkable treatment? He gives no reference to any other authority who may have recommended it, and so we presume he is responsible for it. Again, is it generally accepted that the placenta sometimes extends through the inner os in placenta prævia, reaching "as far as the vaginal surface of the vaginal portion"? Surely such a condition, if ever found, is very rare, and the authority for its occurrence should be mentioned. The treatment recommended in cases of placenta prævia, where atrophy of the placenta cannot be awaited, is distinctly composite, and consists in first dilating the cervix, then detaching the placenta, and then turning. The treatment recommended in accidental hæmorrhage is to rupture the membranes—and then, if necessary, *accouchement forcé*. In post-partum hæmorrhage, a clean rag or pocket handkerchief soaked in vinegar is often the best available method of treatment. "This sounds antiquated in our days, when we hear only of aseptic gauze, sterilised fluids, and disinfected hands," says the author, but surely it would have been better if he had told his students what they must carry with them in order to be able to treat post-partum hæmorrhage, rather than imply, as he does, that proper treatment can only be carried out in hospital and wealthy private practice, and that in the common run of practice it is a case of a clean rag and a bottle of vinegar. It is no wonder that Dr. Garrigues does not include advance in the treatment of hæmorrhage in the four really great improvements in modern midwifery.

Dr. Garrigues' work, however, presents many good points. The illustrations are, as a rule, admirable, with a few exceptions. There is a curious picture on p. 389, which represents an attempt to break the femur of a fœtus while extracting it as a breech presentation by means of a file. Doubtless, however, the words "improper application of" have been omitted.

The publisher's part of the work before us is good; printing, paper and binding are alike excellent.

BLAND-SUTTON ON LIGAMENTS: THEIR NATURE AND MORPHOLOGY. (a)

THE avowed object of this little book is to render more interesting to the mind of the student the ordinary dry anatomical facts which must be learnt concerning the ligaments and fasciæ of the body, by placing before him in a concise and easy manner the morphology and genetic development of these structures, and that it has largely succeeded in its object is proved by the fact that it has now reached a third edition.

Its general plan is admirably adapted to show the manner in which structures become modified in correspondence with an altering function, the result of changes of habit or environment, and to explain the occasional anomalies which often prove so puzzling to a first-year student. It is, however, more suited to be placed in the hands of advanced students who have already mastered the elements of human anatomy and embryology than in the hands of those who have only entered upon these subjects. From the nature and size of the book it is necessarily somewhat fragmentary and dogmatic, but its principal conclusions will be found to coincide with general present-day anatomical teaching.

"Ligaments—Their Nature and Morphology." By J. Bland-Sutton. Third Edition.

Among minor points we may mention that the use of the term "calcaneo-metatarsal ligament" in connection with the long and short plantar ligaments (pp. 28 and 29) is liable to cause some confusion, as that term is now applied to the slip of the plantar fascia which extends from the os calcis to the fifth metatarsal bone. Gimbernat's ligament (p. 75) is stated to be one of the representatives in man of the epi-pubic bone, but those who have dissected the part carefully, and have found the above-mentioned ligament to be derived from some of the fibres of Poupert's ligaments, reflected backwards to the ilio-pectineal line will have some difficulty in accepting this conclusion. Again, many will fail to recognise in the description of the anterior annular ligament of the foot on p. 46 the structure ordinarily seen in the dissecting room; and we believe that the fibrous band (p. 14) described as taking the place of the crico-brachialis brevis in man is not so constantly present as the author states.

An inference is drawn from the fact that the posterior interosseous nerve of the fore-arm ends on the dorsum of the hand in a mass of fibrous tissue, but no reference is made to the fact that the outer branch of the anterior tibial nerve of the leg ends in a similar manner in the dorsum of the foot. On the other hand, a very careful description is given of the parts derived from the subclavius muscle, and also of the relation of the ligamentum teres to Garrod's musculus ambunus; while the chapters on the migration of muscles and on the derivation of the ligaments of the knee-joint are most interesting.

The figures are for the most part poor, especially that on p. 49, but as they seem only intended to be diagrammatic the fact can hardly be regarded as a fault.

The book is nicely bound, is printed in a clear type on good paper, and is provided with an index.

CHAPIN ON INFANT FEEDING. (a) ¶

This volume is an excellent and concise description of the various matters which concern the feeding of infants. In contradistinction to those works which devote themselves especially to describing the various methods of obtaining a suitable infant food that chemically approaches the composition of milk, in the book before us the author lays special stress upon the function of milk in developing the digestive tract of the young animal. The work is divided into four parts. The first of these deals with the underlying principle of nutrition, the second with raw food materials, the third with the practical feeding of infants, and the fourth with the growth and development of infants.

The information given is practical and useful, and is laid before its readers in a clear manner. In the last part there are some admirable photographs of infants at different ages, and various important statistical tables of infant development. There is also a table of reference to other works of a similar nature to, or connected with, the subject of the book. We can recommend Dr. Chapin's work to all who are interested in the feeding of infants, and in the improvement of the present system of milk supply.

AN ATLAS OF ABDOMINAL HERNIAS (b)

THE work before us is one of the important series of German Medical Hand Atlases which have been introduced to English-speaking readers by the American publishers, Messrs. Saunders and Co. It was written by its author, Dr. Sultan, with the object of imparting a thorough knowledge of the subject of abdominal hernias, and of the various details which influence the

(a) *The Theory and Practice of Infant Feeding, with Notes on Development.* By Henry Dwight Chapin, A.M., M.D., Professor of Diseases of Children at the Post-Graduate School and Hospital, etc., etc. London: Bailliere, Tindall, & Cox, 1902. Demy 8vo. Pp. XII. and 326. With numerous illustrations. Price 10/6.

(b) *Atlas and Epitome of Abdominal Hernias.* By Dr. George Sultan, First Assistant in the Surgical Clinic in Göttingen, Prussia. Translated from the German by William B. Coley, M.D., Clinical Lecturer on Surgery, the Columbia University. Philadelphia and London: Saunders & Co., 1902. Pp. 277, with 119 illustrations, 36 of them in colours.

treatment of these conditions—conditions which so often threaten the life of those who suffer from them. In order to facilitate the preparation of correct illustrations, Professors Braun, Orth, and Merkel have placed at the disposal of the author the large amount of surgical material of the Surgical Clinic at Göttingen, as well as that of the Institute of Anatomy and Pathology. The result is that the author is able to lay before his readers a most comprehensive series of coloured drawings made from actual specimens, and of diagrams.

The text of the Atlas is divided into two parts. The first of these deals with the subject of hernia in general—its origin, diagnosis, and treatment. The second part deals with special hernias. The remarks of the author on the subject of the employment of taxis, in cases of strangulated hernia may be strongly endorsed, and commended to the attention of those who are disposed to look lightly on the risks which attend this procedure. An interesting account of the mechanism of strangulation and of the various experiments which have been made by Busch and others with the object of demonstrating that mechanism is worthy of careful study. The Atlas constitutes an excellent guide to the subject of which it treats, and may be strongly recommended to those who require a knowledge of this often vitally important subject.

LEWERS ON CANCER OF THE UTERUS. (a)

THIS volume is an interesting and important addition to the literature of cancer of the uterus. It treats its subject from a purely clinical standpoint and furnishes the after-results of seventy-three cases in which a radical operation was performed. That these after-results have been to some extent favourable may be judged from the statement in the preface that the intention of the author is to bring into prominence the fact that if the condition be operated upon at a reasonably early stage there is a very good prospect that permanent relief will be secured.

The keynote of the book so far as diagnosis is concerned is to be found in attention to clinical phenomena, and we cannot help thinking that perhaps this point is a little unduly dwelt upon. Clinical phenomena are most interesting and of considerable practical importance, but they differ to a very marked extent in different cases, and even when all is said about them that can be said, they will still leave the observer in some cases in a condition of uncertainty. Dr. Lewers, with his large experience of the different aspects of malignant disease, can describe all, or nearly all, those aspects, and can make, with tolerable certainty, a diagnosis from the appearance of a particular growth; but is it possible for a general practitioner with small experience to do so? Dr. Lewers doubtless says that he can be made to do so by being taught. We doubt it, and even if it is possible to teach him is the general practitioner in a better position than one who recognises that any atypical growth may be cancer, and that it is wiser to remove a fragment of it and examine it microscopically, or are the patients of the former safer than those of the latter? Clinical phenomena are excellent things to make the examining physician think, but, in the early cases—on the recognition of which Dr. Lewers so rightly lays stress, they are bad things on which to base a diagnosis. The point must be insisted upon that, for early diagnosis of malignant disease, microscopical examination of a fragment of the growth is essential, and for this reason we must condemn Dr. Lewers' depreciation of the value of, or the necessity for, that form of examination.

The statistics of the cases whose after-history has been followed afford some most interesting information

(a) *Cancer of the Uterus, A Clinical Monograph on its Diagnosis and Treatment, with the After Results in Seventy-three Cases Treated by the Radical Operation.* By Arthur H. N. Lewers, M.D., Lond., P.R.C.P., Obstetrical Physician to the London Hospital, etc., etc. London: H. K. Lewis, 1902. Pp. XIV. and 328, with 51 original illustrations and 3 coloured plates.

on the subject of the value of supra-vaginal amputation of the cervix in cases of malignant disease of that part. Modern opinion would, we fancy, unhesitatingly condemn—as does Dr. Lewers himself—the adoption of such a line of treatment at the present day, and yet we find from the statistics before us that of thirty-three cases in which supra-vaginal amputation of the cervix was performed, eight remained free from recurrence four or more years after operation; while of twenty-eight vaginal hysterectomies, only six remained free from recurrence at the end of a like period. There is, of course, an obvious answer to these figures, that in the nature of things the cases in which supra-vaginal amputation was performed were less advanced than those in which hysterectomy was performed. Still, the figures show that it is possible in certain cases to remove the entire growth by amputation, and so furnish a considerable justification for the adoption of that operation at a time when the mortality of hysterectomy was high. Now, when that mortality has been so greatly reduced, the revival of amputation could not be justified, and in saying that we merely re-echo the opinion of Dr. Lewers, who has abandoned the operation for some years.

The book before us might perhaps be improved in various ways. Personally, we should like the exclusion of long histories of cases and unduly drawn out descriptions of clinical phenomena, and the addition of some chapters on pathology. Then, the work might rank as a monograph of the first rank—a rank which in its present form it is too purely clinical to attain. At the same time it can be strongly recommended, and if it does nothing but direct attention afresh to the vital importance of recognising the existence of malignant diseases in their early stages, it will have done much good.

HERTER ON CHEMICAL PATHOLOGY (a).

THE lectures gathered together in this volume were delivered at the University and Bellevue Hospital Medical College during the seasons of 1899-1900 and 1900-1901. They aim at indicating the leading characteristics of the more important physiological and pathological processes which the student is supposed to study. Unfortunately the slow progress of pathological chemistry has for long stayed advance in practical medicine. Hitherto the medical student has only too frequently looked upon chemistry and pathology as examination barriers to be crossed as early as possible in his course. But Professor Herter, in his luminous and most attractive lectures, conclusively shows the fallacy, and worse, of such an attitude.

The volume is rich in suggestions, and every page indicates the true scientific spirit. It is only possible to indicate in barest outline somewhat of the scope of these valuable lectures. Opening with a discussion of the chemical defences of the organism against disease, the chief food stuffs and their fate in the body, both in health, and disease, are considered at length. A particularly interesting section is that which deals with the fate of iron in the body. Much attention is devoted to the important questions connected with fermentative and putrefactive changes in the digestive tract. The chemical pathology of gastric digestion is also well expressed. Two lectures are devoted to the chemical considerations of hepatic disease, while another deals with diabetes, the concluding one being on starvation, under-nutrition and obesity.

Both in style and matter the work is excellent, and should be well known to English students. At the end of each lecture is a judiciously selected list of the more important works treating on the subject dealt with.

(a) "Lectures on Chemical Pathology in its Relation to Practical Medicine," by C. A. Herter, M.D., Professor of Pathological Chemistry, University and Bellevue Medical School, New York, etc. Pp. 461. London: Smith Elder and Co. 1902.

Medical News.

Dublin University Election and Poor-law Reform.

It is most important that medical graduates of Dublin University who are entitled to vote at the coming election should endeavour to return a candidate who will pledge himself to further by all means in his power the cause of reform in the Poor-law Medical Service. The following letter has been sent to us for publication by Dr. Kinkead, of Galway, and shows that at any rate one of the candidates is determined to endeavour to obtain reform if elected. We shall be glad to give space to the statements of any of the other candidates as to their attitude on this important matter.

30, Merrion Square, Dublin, December 30th, 1902.

Dear Dr. Kinkead,—I shall if returned to Parliament use every effort to obtain redress of the very serious grievances under which the Poor-law medical officers in Ireland suffer.

I think that a reasonable scale of salary should be fixed as a minimum, and an allowance made for expenses, and a fair vacation provided for annually; that a proper scale of remuneration for extra services and for consultations should be fixed; and that adequate payment should be made for discharging temporary duty. It is a scandal that no proper system of superannuation exists, and there ought to be legislation to provide for adequate retiring pensions.

In the case of medical men holding Government appointments which do not require "whole time" services (in the Treasury parlance) there is no sound reason why superannuation allowance should not be made to these officers.

I am aware from discussion with many eminent medical men of various other grievances which affect Poor-law medical men, and I believe that with proper understanding among the members of the profession, and by pressure in Parliament, much could be done to place the service on a reasonable and proper footing.—I am very faithfully yours,

ARTHUR W. SAMUELS.

Conviction for Illegal Use of the Title of M.D.

A person called Martin, a Roumanian, was prosecuted by the Medical Defence Union at Nottingham last week for using the name and title of "doctor," he not being a registered medical practitioner. It appeared that the defendant had been repeatedly warned by the Union but had nevertheless continued to carry on his practice. The defendant stated his intention of abandoning the practice forthwith, and a fine of £5, including costs, was inflicted.

Deaths under Chloroform.

A death under chloroform occurred on the 31st ult. at the Wolverhampton General Hospital, the victim being a lad who was undergoing an operation. A death under chloroform took place at University College Hospital last week, the victim being an elderly man who had sustained a severe compound fracture of the leg, having been knocked down by a van. In this case it is highly probable that death was due to the shock of the accident rather than to the chloroform, but no details were forthcoming as to the method of administration. A verdict of death from misadventure was returned at the inquest.

Sudden Death of a St. Leonard's Practitioner.

An inquest was held on the 27th ult. on the body of Dr. Robert Donald Campbell, of St. Leonard's, who was found dead in his bed. The appearances (?) being in favour of death from heart disease, a verdict to that effect was returned. The deceased was only 35 years of age.

The Annual Increment.

ACCORDING to the 1903 edition of the "Medical Directory," there were 503 additions to the ranks of the profession during last year, the total number now on the Register being 37,291. Of these 6,309 are in the metropolis, 16,422 in the provinces, 3,680 in Scotland, 2,641 in Ireland, and 1,186 in Wales.

Royal Chocolate.

MESSRS. ROWNTREE have once again come to the front in connection with the Queen's Dinner to the poor of London, each of the guests receiving a box of chocolate bearing a medallion of her Majesty in colours. The boxes, which are very daintily decorated, were manufactured by Messrs. Barringer Wallis and Manners, of Mansfield, and, we can quite believe, were highly appreciated by the recipients.

A Royal Food.

It is claimed for Robinson's Patent Barley that it has been used in the Royal nurseries of this country and the Continent form any years, though it is perhaps hardly fair to assert that the Royal children owe any of their stamina to the preparation. An appointment which dates back to the reign of William IV. is nevertheless one to be envied.

The Treatment of Tuberculosis.

The text of the three essays, and the accompanying drawings and plans, which gained the prizes of £500, £200, and £100 respectively, offered by the King for the three best essays on this subject, were published in the *Lancet* of January 3. The total number of essays sent in for competition was one hundred and eighty.

Lemon Juice for Typhoid.

THE experiments of the Chicago Board of Health tend to confirm the recent announcement of Dr. Ferguson, of London, that lemon-juice is inimical to the life of the typhoid fever bacillus. The use of lemon-juice on oysters is consequently recommended as a preventive of typhoid fever infection.

The Registrar-General for Ireland.

THE annual report for 1901 of the Registrar General (Ireland) has just been issued, and it is difficult to say whether we are more surprised at the immense mass of statistics given, or the skill with which they are classified for the reader's convenience. As medical journalists, our principal concern is with the rates of morbidity and mortality. The areas having the lowest registered mortality are Mayo, 12.3; Kerry, 13.5; Leitrim, 13.8; and Galway, 14.6; The rate was highest in Dublin County Borough, 26.8. The diagram on page 8 illustrates forcibly the terrible mortality from tuberculous disease, which caused the death of 12,323 persons during the year; bronchitis, which stood next in lethal properties, caused 8,200 deaths. There were 6,945 deaths referred to zymotic diseases, of which 459 deaths were from measles, 245 from scarlatina, 92 from typhus, 1,381 from influenza, 1,123 from whooping-cough, 370 from diphtheria, 88 from cerebrospinal fever, 86 from simple continued fever, and 829 from typhoid fever. The constitutional diseases, including rheumatism, cancer, and tuberculosis, caused deaths to the number of 16,504. There were 2,893 deaths from cancer, 12,323 deaths from tuberculosis, 190 deaths from rheumatic fever, 477 deaths from rheumatism, 20 deaths from gout, and 57 deaths from rickets. Diseases of the respiratory system caused 13,370 deaths, diseases of the circulatory system caused 7,077 deaths, diseases of the nervous system caused 7,355 deaths, and diseases of the urinary system caused 1,818 deaths. Of infants, 10,101 died under one year old, being equal to 10.1 per cent. of the number of deaths registered. Among the deaths registered 109 were returned as having been 100 years or upwards.

Sir E. Cassel's Munificence.

It is stated that Sir Ernest Cassel, whose munificent gift of £200,000 to the King for consumption sanatoria

will be remembered, has offered to give £40,000 towards the study and investigation of ophthalmia in Egypt.

Pass Lists.

University of London.

**M.B. EXAMINATION FOR HONOURS,
MEDICINE.**

First Class.—Alex Cameron (Gold Medal), James Alane Coupland, Charles Seymour Parker, Robt. Pugh Rowlands (Scholarship and Gold Medal).

Second Class.—Ernest Rock Carling, Lucian A. E. De Zilwa, B.Sc., Charles Ernest Lakin, Wilfred George Mumford, Christopher Thackray.

Third Class.—Hanway Richard Beale, Henry Tregelles Gillett, Andrew Ferguson Horn, Gerald Stephen Hughes, Mabel Halden Naylor, Cecil William Rowntree, Ernest Wethered.

OBSTETRIC MEDICINE.

First Class.—Ernest Rock Carling (Scholarship and Gold Medal), Lucian A. E. De Zilwa, B.Sc., (Gold Medal), Reginald Cheyne Elmslie, Charles Seymour Parker.

Second Class.—Michael Abdy Collins, Friedrich Gröne, Harold Edward Ridewood.

Third Class.—Ethel Florence Iredell, B.A., Charles Ernest Lakin, Winifred Thorp.

M.D. EXAMINATION IN MEDICINE.

Pass List.—Wm. Fielding Addey, B.S., William Blair Bell, Arthur Bevan, Albert Henry Bygott, Arthur Ernest Clarke, David Leighton Davies, B.S., Adèle Isabella De Steiger, Thomas Henry Bourne Dobson, Arthur Eastwood, Henry Percival Ferraby, Edward Alfred Gates, Dudley George Greenfield, Harold Hartley, William Liversidge, Geo. Norman Meachen, B.S., William Tayler Milton, M.S., Adeline Mary Roberts, B.S., Wm. Trethowan Rowe, B.S. (Gold Medal), Henry William Rowland, Alfred Bertram Soltau, Cuthbert Allan Sprawson, B.S., James Ernest Stratton, Hackworth Stuart, Lewis Augustus Walker, Ralph Paul Williams, B.S., William Henry Wynn, B.Sc.

STATE MEDICINE.

Wm. Willoughby Kennedy, Thomas Hy. Craig Stevenson, B.S., Wilfred Watkins Pitchford.

B.S. EXAMINATION PASS LIST.

First Division.—Walter Fedde Fedden, Mary Hannah Frances Ivens, Lawrence Jones, Cyril Alfred R. Nitch, Sydney Richard Scott.

Second Division.—Edward Walter Bain, Ernest Gilbert Bark, Frank Barnes, William Henry Bowen Sidney Herbert Bown, Harold Burrows, Percy Wm. Leopold Camps, Olive Claydon, Michael Abdy Collins, Harold Collinson, David Ellis, Reginald Cheyne Elmslie, Harold Arthur Thos. Fairbank, John Grimshaw, M.D., Stanley Hodgson, Andrew Ferguson Horn, Alfred Ernest Jones, Thomas Lister Llewellyn, Herbert W. Lyle, M.D., Edward Lister Martin, Mabel Halden Naylor, William Paynter Noall, Alfred Gelsthorpe Osborn, Herbert Dean Pollard, Robert Pugh Rowlands, Chas. Cecil Connock Shaw, Christopher Thackray, Winifred Thorp, William Howard Union, Frederick Edward Walker, Charles Wynn Wirgman.

M.S. EXAMINATION PASS LIST.

Felix Bolton Carter, M.D., Herbert Sherwell Clogg, (Gold Medal), Herbert Lightfoot Eason, M.D., Russell Henry Jocelyn Swan.

B.S. EXAMINATION FOR HONOURS, 1902.

First Class.—Lawrence Jones, Cyril Alfred R. Nitch (Scholarship and Gold Medal), Sydney Richard Scott (Gold Medal).

Second Class.—Walter Fedde Fedden, Mary Hannah Frances Ivens.

Notices to Correspondents, Short Letters, &c.

✍ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

F. B. Y.—Nothing could be more calculated to cause estrangement between the parties than following the course which our correspondent proposes to adopt.

Dr. G.—Our correspondent is advised to leave the matter alone.

Dr. H. B. (St. Etienne).—Glad of the information.

Mr. M. W. C.—Your letter surprises us; we thought the matter had been arranged satisfactorily to both. Our advice still is, keep out of the hands of lawyers. The point is not worth fighting over, with the attendant costs and anxiety.

T. F. C. (London).—Most medical journals are accessible in the libraries of the Royal College of Physicians and the Royal College of Surgeons.

A LABEL ON SURGERY.

"Various canny underwriters grew fat on the proceeds of the small-pox insurance. And now we are all solemnly insuring against appendicitis, not so much because we are afraid of getting it, but because we feel quite sure that sooner or later our medical advisers will operate upon us for it.—*The Outlook*."

SENEX.—Cannot do better than submit to the decision of the committee.

AN OPENING FOR PRACTICE

The West Indian island of Nevis has 13,000 inhabitants, and there is only one resident medical man to attend to them all. There is an excellent opening for an enthusiastic young practitioner. No premium!

Dr. MYTHE.—The full report has not reached us. When it does we will deal with the incident editorially.

XERES.—No such communication has been received or refused by the Editor.

CRYOSCOPY.

Cryoscopy is the term applied to the process of differentiating between various fluids and solutions by determining their freezing point. This varies within wide limits, and certain deductions have been drawn from the results thus obtained.

VERAX.—Legal measure are not to be recommended under the circumstances because it would be a costly and difficult matter to obtain reliable evidence.

R.S.O.—We are unable to publish your letter by reason of the defamatory nature of many of the allegations. If correct the matter is one to be threshed out in the Law Courts but the expediency of so doing must be decided by your solicitor.

THE SYMPTOMS AND DIAGNOSIS OF TUBERCULOUS PERITONITIS.

Referring to a paper on this subject, which appeared in our issue for Dec. 25th, the Hon. Secretary, Dr. Sydney Stephenson, writes:—"It is only right to state that the original paper was read at a special meeting of the Society for the Study of Disease in Children on December 12th, 1902. I am confident that the author would wish this fact to be acknowledged, and it is almost certainly by a pure oversight that it has not already been done."

Meetings of the Societies, &c.

WEDNESDAY, JANUARY 7TH.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Discussion on Puerperal Insanity opened by a paper by Dr. R. Jones (Claybury) (introduced by Dr. W. S. A. Griffith) and continued by Sir J. Williams, Bart., Dr. W. L. Andriezen, Dr. G. F. Blandford, Dr. F. H. Champneys, Dr. W. S. A. Griffith, Dr. G. E. Herman, Dr. T. B. Hyslop, Dr. C. Mercier, Dr. W. D. Moore, Dr. F. W. Mott, Dr. G. H. Savage, Dr. P. Smith, Dr. S. Tuke, and Dr. E. White.

THURSDAY, JANUARY 8TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Annual General Meeting. Election of Officers. President's Address. Annual Conversazione.

FRIDAY, JANUARY 9TH.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi Terrace, Strand, W. C.).—7.30 p.m. Dr. A. Hillier: The Prospect of Extinguishing Tuberculosis.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—4.15 p.m. Annual Meeting, 5 p.m. Ordinary Meeting. Cases, Specimens and Instruments will be shown by Mr. W. H. R. Stewart, Sir Felix Semon, Dr. Bronner, Dr. W. Williams, Dr. Lack, Mr. Lake, Dr. Tilley, Dr. B. Baron, Dr. Donelan, and others. 7.45 p.m. The Annual Dinner of the Society will take place at the Café Royal.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Papers:—Mr. T. H. Openshaw: The Morbid Anatomy and Treatment of Congenital Dislocation of the Hip-Joint. Dr. E. W. Goodall: A Case of Haemorrhagic Typhoid Fever. Dr. H. D. Rolleston: Generalised Tuberculosis with Arthritis.

Appointments.

DEWDNEY, Mr., Medical Officer for the Kingstonswell District by the Newton Abbot (Devon) Board of Guardians.

HAY, JOHN, M.D. Vicar, Honorary Assistant Physician to the Hospital for Consumption and Diseases of the Chest, Liverpool.

SHARP, H. C., M.B., B.C. Camb., Medical Officer of the Kenwyn District of the Truro Union.

STACK, E. H. EDWARDS, M.B., B.C. Cantab., F.R.C. Seng., House Surgeon to the Bristol Royal Infirmary.

Vacancies.

Borough Hospital, Birkenhead.—Senior Resident Male House Surgeon. Salary £100 per annum, with board. Applications to Chairman, Weekly Board.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Physician to the Out-patients. Applications immediately to the Secretary at the Hospital.

County Asylum, Whittingham, Preston, Lancashire.—Assistant Medical Officer. Salary £150, furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Nottingham General Hospital.—Assistant House Surgeon. Salary £100 with board, lodging, and washing in the Hospital. Application: immediately to the Secretary.

Royal Dental Hospital of London and London School of Dental Surgery Leicester Square, W. C.—Demonstrator. Salary £200 per annum Applications to Morton Smale, Dean.

Royal City of Dublin Hospital, Resident Medical Officer. Applications to G. Jameson-Johnston, F.R.C.S. (See advt.)

Royal Victoria Hospital, Bournemouth.—House Surgeon. Salary £10 per annum, with board and lodging. Applications to the Chairman of Committee.

Sheffield Royal Hospital.—Junior Assistant House Surgeon. Salary £50 per annum, with board, washing and lodging. Applications to the Secretary to the Honorary Staff, Dr. Stanley Riseley, 38, Glossop Road, Sheffield.

Surrey Dispensary, Southwark, S.E.—Resident Medical Officer. Salary £140 per annum, with furnished apartments, coals, gas, and attendance. Applications to W. R. Millar, Secretary, 53, Borough High Street, Southwark.

The General Infirmary at Gloucester and the Gloucestershire Eye Institution.—Senior House Surgeon. Salary £100 per annum, with board, residence and washing. Applications to the Secretary.

Wandsworth and Clapham Union Infirmary, St. John's Hill, S.W. (near Clapham Junction).—Junior Assistant Medical Officer. Salary £100 per annum, board, lodging and washing provided. Applications to the Medical Superintendent.

Marriages.

WINGATE—BURNETT.—On Dec. 31st, at St. Mary Abbot's Church Kensington, Major Harold Fenton Wingate, the Royal Scots, 1 Ethel Mary, eldest daughter of Surgeon General W. F. Barnett A.M.S., P.M.O., Bengal command, and granddaughter of the late Thomas E. Herrick, of Shippool, co. Cork.

Deaths.

REID.—On Jan. 4th, at 12, Lower Bridge-street, Canterbury, Ellen wife of James Reid, F.R.C.S., in her 81st year.

SHILLITO.—On Jan. 5th, at 6, Burston-road, Putney, after two days illness, William Shillito, F.R.C.S.E., late Bengal Army, in his 87th year.

OPERATIONS.

METROPOLITAN HOSPITALS.

WEDNESDAY (7th).—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.) Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street (9.30 a.m.), Gt. No. 2.

Original Communications.

A CASE OF HÆMORRHAGIC TYPHOID FEVER (a)

By E. W. GOODALL, M.D.

THE patient in this case was Mary C., æt. 26, an assistant nurse at the Eastern Fever Hospital, Homerton. She entered the service of the hospital in November, 1898; since that date she suffered at different times from scarlet fever, diphtheria, and rubella. At the commencement of her fatal illness she was employed on night-duty. She made no complaint till the evening of January 20th, 1902, when she said she felt too unwell to get up and go on duty. She was seen by one of the assistant medical officers, who found her temperature raised, some purpuric spots on the legs, and an erythematous rash diffused over the trunk, which led him to suspect scarlet fever. The young woman was complaining of headache; she stated that she first noticed the spots on the legs when she was going to bed that morning, and that she had been suffering from headache and pains in the limbs and back since January 12th. There was no shivering and no vomiting.

January 21st.—At 2 a.m. the patient's temperature was 104° F.; pulse, 130, compressible; heart normal; lungs normal; skin yellowish, but not bile-stained; expression of face anxious; mind quite clear. On the front of the legs below the knees were a number of purpuric spots; there were also similar spots on the upper parts of the chest and arms, the lower part of the neck, and about the axillæ. Most of these spots were about the size of a large pin's head, though some of those on the shins were petechial. In addition to these cutaneous hæmorrhages was one blue subcutaneous hæmorrhage on the lower and outer part of the right upper arm. Blood was oozing from the gums and lips, and there were hæmorrhages in the mucous membrane of the mouth. Although it was not due for a fortnight, menstruation had commenced. The urine was of natural appearance. The erythema disappeared before morning.

22nd.—Some more purpuric spots have appeared on the arms, and there is a subconjunctival hæmorrhage on the right side. The menses are more copious and contain more blood than is usual for the patient. At 2 p.m. a pint of opaque urine, of the colour of burnt sugar, was passed. It gave the reactions for blood. Yesterday morning the patient was put on a mixture containing calcium

chloride, 15 grs. every four hours; this evening 10 minims of a 1-1,000 solution of adrenalin chloride was ordered instead, every four hours.

23rd.—There is a large, fresh hæmorrhage into the buccal mucosa on the right side, and some more blue subcutaneous hæmorrhages on the right hand and forearm. There is less bleeding from the gums and much less menstrual flow; but the condition of the urine is about the same. Pulse small; patient put on champagne. In the afternoon she was prostrate; she was anxious; and as she was also unable to sleep, she was given a $\frac{1}{2}$ gr. opium pill, which had the desired effect.

24th.—Has vomited two or three times since last night; vomit "coffee-grounds" in character. Very little oozing of blood from mouth and very slight menstrual flow. Breathing shallow and quick, but no abnormal signs in the chest. Bowels confined; glycerine enema ordered. The urine is the same as before; when examined microscopically it was found to contain nothing but blood cells.

25th.—Pulse inclined to be running; retching at times; some bleeding from the mouth during the night; still a little hæmorrhage from the uterus; the urine contains blood. Skin has a yellowish tinge. Since the commencement not many more cutaneous hæmorrhages have appeared; they are mostly on the limbs; the large sub-cutaneous hæmorrhages are on the thighs, upper arms and forearms, and there is one on the left hand. There have been no violet or ink-like spots or effusions of blood as in variola. The breath is very fœtid, and blood collects in a crust on the lower lip. The bowels were moved after the enema yesterday; the motions were very black and streaked with bright blood. Up to to-day the patient has been taking food pretty well, but to-day she is not.

26th.—No bleeding from the mouth or uterus to-day. Patient looks very ill, and is worse. Vomiting during the day. The urine, which was clear and almost transparent all day, became turbid and brown in the evening, and deposited a thick, chocolate sediment. The patient is becoming restless, but is at the same time languid and disinclined to speak; at times she is drowsy.

27th.—Retching occasionally; urine a little darker than yesterday; mind quite clear; a little oozing of blood from the mouth.

It is hardly necessary to give details of the case between this date and the patient's death, which took place at 11.30 p.m. on February 2nd. No fresh hæmorrhages appeared, and as far as appearance went the urine became free from blood. The pulse and respiration rate were high; the breathing became shallow, and there was an occasional

(a) Paper read at meeting of Clinical Society, January 9th, 1903.

cough; till two days before death the temperature was considerably raised. Up to January 27th the bowels had been confined; after that they were opened more often, the stools being small, clay-coloured, but not very loose; at no time were they "pea-soupy." The patient was restless, had only snatches of sleep, and wandered at times; towards the end she became unconscious. On January 30th she had lost the ghastly, yellow look she had previously presented, and had become extremely pallid. There was occasional retching. The pulse very gradually failed; indeed, for the last five or six days her death was hourly expected. During the last few days there was incontinence of urine and fæces.

A post-mortem examination was made on February 3rd at 5.30 p.m. Rigor mortis present; universal yellowness of skin, not due to bile; body in a good state of nourishment; fat more yellow than usual. The purpuric spots observed during life were still present, though somewhat faded. They were to be seen on the face and chin (a few only); lower part of neck and upper part of chest; upper extremities, especially on the extensor surfaces; upper and outer parts of thighs; shins and dorsa of feet. On the shins and feet the spots were petechial, and of a very red colour; elsewhere they were larger and of a faded purple hue, two or three lines to a quarter of an inch across. On the arms, hands, and thighs were also a few larger subcutaneous hæmorrhages, half an inch to one inch in diameter. There was a small, subconjunctival hæmorrhage in the left eye.

Many hæmorrhages were found in the parietal peritoneum. There was also a good deal of hæmorrhage in the connective tissue round the right kidney and some into the omentum and mesentery. No peritonitis.

Spleen.—4½ ozs.; quite firm and normal.

Kidneys.—Left, 5½ ozs.; pale and somewhat blurred, otherwise normal. Right, 8½ ozs.; pale; round it much extravasation of blood; pelvis and calices full of recent blood clot; many small hæmorrhages into substance, especially near the surface; many groups of yellowish spots, size of sago grains, seen on surface; they stood out above the surface; when cut into they showed the same appearance and extended deeply into the organ; structure of kidney coarse and mottled.

Adrenal bodies, normal. *Pancreas*, normal. *Liver*, pale, but normal. *Gall-bladder*, small, normal, contained yellow mucus. *Stomach*, pyloric end showed a very large number of petechial hæmorrhages over an area of several square inches. *Uterus*, normal. *Ovaries*, right, a large Graaffian follicle full of recent clot, half an inch across; left a similar follicle but older, with breaking down clot. *Bladder*, many submucous hæmorrhages, some of them half an inch or more across.

The *intestines* showed many large submucous hæmorrhages, especially in dependent loops. A good many ulcers were found, the highest 2½ ft. above the ileo-cæcal valve. These ulcers were situated in Peyer's patches and solitary follicles, mostly the former, except near the valve, where for three or four inches was a good deal of irregular ulceration; except here the ulcers were mostly round. Their edges were clean cut and slightly undermined; there were no sloughs anywhere. All except three or four of the smallest ulcers were situated in the midst of patches of submucous hæmorrhage, so that the question was raised

whether the ulcers were not the result of the hæmorrhages. But I thought not; they were too defined and deep, and they looked just like typhoid ulcers of the third or fourth week. There were a good many small round ulcers in the upper half of the large intestine. The mesenteric glands were considerably enlarged, and infiltrated; into most of them hæmorrhage had taken place.

Heart, normal. *Lungs*, old adhesions over nearly the whole of the left lung and between the lobes of the right. The posterior and lower parts of both lungs were extremely oedematous and airless, but there was no consolidation or recent pleurisy. No other organs were examined.

A *microscopical examination* of the various organs was made by Mr. Dunstan Brewer, who has kindly furnished the following description:—

Spleen, normal; no organisms to be seen in the sections made. *Kidneys*: Left, cloudy swelling, with slight desquamative nephritis; no organisms, no hæmorrhages. Right, cloudy swelling and focal necrosis; early desquamative nephritis and glomerulitis. The small white patches are septic foci, consisting of masses of small round cells, showing little tendency to necrosis. In typical masses the centre consists of a mass of organisms (bacilli coli?). The tubules are filled with debris, chiefly consisting of round cells and broken-down blood. There are numerous hæmorrhages, mostly recent. Both the hæmorrhages and the septic foci are mainly in the medulla. There are no cocci in either kidney.

Pancreas, normal. *Liver*, slight granular degeneration, with small masses of young connective tissue and early necrosis in parts; no fat; no hæmorrhages; plugs of streptococci in capillaries. *Uterus*, normal. *Heart*, slight granular degeneration; no vacuolation; increase of inter-muscular tissue; small inter-muscular hæmorrhages; a few masses of streptococci in vessels.

Lungs, patches of broncho-pneumonia, in places breaking down into pus; general oedema; masses of streptococci, chiefly in and near vessels and suppurative foci.

As no Widal's test had been done during life, some of the blood was taken from the heart and the test tried post-mortem. The reaction was observed well within half an hour with a 1 in 20 dilution, but only very slightly within half an hour with a 1 in 40.

Agar cultivations were taken at the autopsy from the heart-blood, the spleen and a mesenteric gland. Dr. Cartwright Wood very kindly examined the resulting growths. The culture from the heart-blood gave a growth of bacillus coli, while those from the spleen and mesenteric gland resulted in growths of *B. coli* and *B. typhosus*. The latter gave all the reactions, including agglutination, with a specific serum. Organisms that liquefied gelatine were also obtained from the mesenteric gland; but they were not further identified.

Clinically this case was very obscure. The nurse had not been employed in a typhoid fever ward. At first the symptoms were only those of acute purpura hæmorrhagica. The patient had been vaccinated in infancy, and again on entering the service of the hospital in 1898, and had seven very good marks on the left arm; so that the facts as to vaccination and revaccination, quite apart from the absence of other symptoms, negated the idea of small-pox, which was very prevalent at the

time. After a day or two I thought that the hæmorrhage was only symptomatic of an acute general infection (streptococcal infection or something of that nature?). On the evening of January 29th I began to have suspicions of typhoid fever, but I never had more than suspicions. I examined the patient carefully on that night, as well as on other occasions, but could find no definite evidence of typhoid fever; but I noticed that the abdomen was a little full and the muscles a trifle resistant. No spots were ever seen, either by myself or by Dr. Basan, under whose immediate care the patient was. Nor was there anything in the condition of the bowels to suggest typhoid. Yet the post-mortem examination showed that the case was certainly one of typhoid fever.

It is a well-recognised fact that hæmorrhage into the skin and organs and from mucous surfaces may occur with varying frequency in several of the acute infectious diseases. In small-pox and diptheria, indeed, this complication is common; but in typhoid fever it is very rare; and it is partly on this account that I publish this case. Trousseau mentions the condition under the name of "hæmorrhagic putrid fever," but the case he relates was not a marked one. Murchison simply mentions the fact that such a form of the disease is sometimes met with. Curschmann, the writer of the article on typhoid fever in "Nothnagel's Cyclopædia," states that he has observed only six cases; he quotes Liebermeister as having seen three among 1,900 cases of typhoid fever in an epidemic at Basle, and Weil one in 150. Osler, the editor of the English edition of Curschmann's article, adds that at the Johns Hopkins Hospital only one case occurred among 829 cases of typhoid fever.

On looking up the notes of the cases at the Eastern Hospital, Homerton, I find that the case I have just related is the only marked one occurring during the period I have been connected with the hospital, from January, 1892, to December, 1902—eleven years. During this time the number of typhoid fever admissions has been 1,733, including cases occurring among the staff, so that the complication is decidedly rare. I find, however, that there have been fifteen cases, including the present one, in which hæmorrhage other than intestinal has taken place. In fourteen of these cases there was hæmorrhage, either purpuric or petechial, often both, into the skin, and in one from the gums, lips, and palate, but not into the skin. Among the fourteen cases in which it occurred in the skin it appeared in other places as follows:—Fauces, one case; nose, one case; pleuræ, one case; lungs, one case; nose and mouth, two cases (one of these cases had cancrum oris at the same time); beneath the conjunctiva and into the mesentery, pleuræ, and larynx, one case; nose, mouth, and uterus, one case; and, lastly, the present case, in which the eye, mouth, uterus, kidney, bladder, peritoneum, and stomach were affected. There were, therefore, five cases only in which the skin alone was involved; one of these cases was fatal from pneumothorax, but the patient was seriously ill with typhoid fever before this complication arose.

All but three of the fifteen cases died; in one of the cases that recovered the skin alone was involved; in another there was bleeding from the fauces; and in the third from the nose. In none of these cases were the hæmorrhages extensive or

severe. An extensive purpuric or petechial eruption, therefore, in typhoid fever justifies a very grave prognosis.

Nine of the fifteen patients were between the ages of five and fifteen years; the oldest was a man of thirty, the youngest a girl of five. Eight of the patients were males and seven were females.

In none of the cases except the present has the hæmorrhagic condition arisen earlier than the second week of the disease; this case is unusual in that hæmorrhages were amongst the first noticeable indications of illness.

The etiology of hæmorrhagic typhoid fever has been well discussed by Nicholls and Learmonth, of the McGill University, Montreal, in a paper in the *Lancet* for February 2nd, 1901. These authors give a list of the various causes to which this condition has been ascribed—alcoholism (especially by the French writers); defective nutrition due to scurvy, overcrowding and scanty food; attacks of another infective disease immediately before the attack of typhoid fever; the cold bath treatment; a family idiosyncrasy; and, lastly, bacterial activity. In the present case none of these causes except the last were present, though it is perhaps worthy of note that the patient had suffered from three other infectious diseases during the previous two years; but in none of these was the attack severe. In cases of this kind it is very probable that the hæmorrhagic state is due to the action of bacteria or their toxins. In the case they investigated, Nicholls and Learmonth found the staphylococcus pyogenes albus in the heart-blood, peritoneal cavity, and the kidneys. They also demonstrated a fatty degeneration of the basement membrane of the capillaries and of various endothelial cells, especially noticeable in the lungs and kidneys. I regret that the present case was not sufficiently worked out to show what part, if any, was played by bacteria. But the presence of micro-organisms in the centres of the inflammatory foci in the kidney is significant, seeing that hæmaturia occurred early in the disease.

TWO UNUSUAL CASES OF NEPHRECTOMY (a)

By R. CHARLES B. MAUNSELL, M.B., B.Ch.,
Univ. Dub., F.R.C.S.I.,
Surgeon to Mercer's Hospital, Dublin.

MR. PRESIDENT AND GENTLEMEN,—The operation of nephrectomy has been so long before the profession, and the subject has become so vast, that I have neither the inclination nor the experience to deal with more than a few points this evening.

The two cases which I bring under your notice in this communication have been chosen as they occurred in my hospital practice at about the same time, and illustrate fairly well two very different forms of nephrectomy.

The first case is undoubtedly unusual and worthy of record from this point alone. The second I can hardly claim to be very unusual, but I wish to make a few remarks about it, so that I may elicit the practical experience of my senior brethren.

Case I.—Bridget L., æt. 16 months, was sent to me on June 5th, 1901, by Dr. Lloyd, who was at that time Assistant Master of the Rotunda Hospital. The mother, who brought the child,

(a) Read before the Surgical Section of the Royal Academy of Medicine in Ireland, December 12th, 1902.

is a healthy-looking woman, and stated that the child's father is also healthy. The patient is the youngest of a family of four, all of whom are alive. At birth, and for three months subsequently, nothing abnormal was noticed, but then the mother, when bathing the child, felt a lump like an egg on the right side of the abdomen. The child remained in good health and the lump did not increase in size for seven months, but then grew rapidly and continuously up to the date on which I saw her. Nothing abnormal was ever noticed in the urine or motions, and the only other fact of importance was that, as the abdomen increased in size, the limbs and face showed signs of wasting.

On examination, the child seemed rather puny and weak, and would not lie down, but preferred to sit up, even when dozing or asleep; there were no signs of rickets or syphilis, and the heart and lungs seemed normal; the urine was passed into a napkin, but a small specimen which was obtained showed neither albumin nor casts; the abdomen was very much distended both antero-posteriorly and laterally; the subcostal angle was lifted up and opened out; the right loin bulged more than the left, and the right lumbar hollow was obliterated when viewed from behind.

On percussion the only resonant area was over the left hypochondrium and left lumbar region.

On palpation, a firm but not very hard tumour was felt, practically filling the whole abdomen; it seemed to be trilobed, the largest portion passing beneath the ribs and liver, a somewhat smaller portion passing down, filling the false and dipping into the true pelvis, the third portion bulging in the right lumbar region; the abdominal walls were tense but movable over the tumour.

The diagnosis rested between ovarian tumour, sarcoma of the kidney, or congenital cystic kidney, and having considered the various signs I gave the last as the diagnosis, and recommended abdominal exploration and removal, if possible.

The operation was performed on June 13th, 1901. The thorax and limbs having been carefully wrapped up in wool, ether was administered, and the child placed on her back upon the operating table. An incision was made commencing opposite the tenth intercostal space, extending obliquely downwards and forwards to a point near the middle line below the umbilicus, the fibres of the external oblique were separated as much as possible and the internal oblique and transversalis cut, the sheath of the rectus was opened by cutting through the linea semilunaris, and its anterior and posterior layers cut across with scissors without injury to the muscle, which could then be easily drawn to the middle line. The tumour presented a bluish colour in parts, alternating with more yellowish-white; it was extra-peritoneal except on its anterior and left aspects.

The peritoneal cavity was then opened at the innermost part of the wound, and the left kidney palpated and found to be apparently normal. The upper portion of the tumour was next rapidly separated from its adhesions and withdrawn from the wound, thus exposing the renal vessels, which were small and easily secured by fine silk ligatures, and divided; the tumour and ureter were then further drawn outwards, the ureter ligatured and divided at the brim of the pelvis and the lower

lobe of the growth drawn upwards, thus completing the removal. Some vessels which had been clipped were ligatured, the peritoneum and sheath of the rectus repaired with fine silk, and the rest of the incision through the muscles united by a continuous buried silk suture, and the skin closed by fishing-gut without drainage. Before removal of the tumour the incision seemed about 22 cms. long, but after removal shrank to 10 cms. After operation the child weighed 17½ lbs., and the tumour weighed 3 lbs. 2 oz.

Convalescence was absolutely uneventful, and the child was sent home on July 2nd—twenty days after operation. Since then she has grown to be a fine little girl, apparently normal, and when seen during the latter part of August, 1902, the left kidney could not be palpated, and was evidently doing its double work satisfactorily.

There are just a few remarks I would like to make about this case before proceeding to the next one.

Ether was chosen for anæsthesia, as the shock from its administration is slight, and also I wished to be able to devote my undivided attention to the operation. It is a fairly general idea that children take ether badly and take chloroform well, but I can, after a considerable experience in performing both large and small operations upon very young children, emphatically state that children take ether well, become unconscious as soon or sooner than with chloroform, recover much more rapidly from its effects, and so far I have not had any pulmonary complications following its administration.

The next point of importance is to wrap a small patient like this in wool and have the theatre extra warm. With regard to the actual operation on young children, the important points are: accurate hæmostasis, absolute asepsis and rapidity. In the foregoing operation the total amount of blood lost did not exceed two drachms, and the lotion used for cleansing the wound, &c., was simple normal saline solution.

Surgery has now advanced so far that the age of a patient is no longer of consequence; the only objection which can be raised against operations upon infants is on the score of expense, as these little patients require the undivided attention of a nurse both by day and by night.

The choice of an incision is not always easy, and it is of very great importance in nephrectomy and other kidney operations.

We may discard the middle line as unsuitable in any case. Langenbuch's incision has been out-classed, and, in the present case at any rate, would have made the operation very difficult, besides destroying the nerve supply of a large portion of the rectus.

Langenbuch's, with a cross-cut to the loin, would have given very ready access, but to my mind is unsurgical, and needlessly destructive. The combined methods of Morris and Thornton do not appeal to me. The lumbar incision and its various modifications are out of the question because the position of the patient is faulty, the wound is deep and needlessly severe, and although one of the modifications gives plenty of room below, the space above is cramped, and it might also be necessary to make a separate incision for abdominal exploration.

A very good incision for removing large tumours is that of Bergmann, as advocated by Kocher, *viz.*, an oblique incision commencing above at the tip of the tenth or eleventh rib and sloping down to the centre of Poupart's ligament; or a modification of this which is a most useful incision for many kidney operations, and which can be either extra- or intra-peritoneal according to the class of case, commences above at either the tenth or eleventh intercostal space or immediately below the tip of the last rib, and slopes forwards and downwards in the direction of the external oblique fibres and reaches the linea semilunaris or middle line if necessary at a varying distance below the umbilicus. If it is necessary to reach the middle line, the rectus should not be cut, but the linea semilunaris should be snipped through, and then the anterior and posterior layers of the sheath cut with scissors and the muscle drawn aside. This incision gives very free access to the upper part of the kidney as well as to the whole ureter. The special method of dealing with the sheath of the retcus was used by me first some three years ago when exploring the upper abdomen, and I have used it several times since to give more room in the removal of the appendix by the muscle-splitting method. If the kidney is only to be explored or fixed, the whole procedure may be carried out by the muscle-splitting method, as I have proved to my own satisfaction in three cases.

Case II.—Mrs. S., *æt.* 40, had her uterus removed by vaginal hysterectomy for carcinoma in July, 1900.

The operation was very difficult, and some days afterwards quantities of urine were noticed coming per vaginam, evidently from an injured ureter. It was considered better not to open the abdomen to perform an implantation operation as the pelvis was obviously septic. She progressed favourably except for the fistula, and was discharged on September 29th. She was admitted again in December, and I examined her by Kelly's method, and could make out that the left ureter was the one involved, but as there was a suspicion of recurrence of the carcinoma, no operation was advised, and she was not again seen by me until June, 1901, when I found that she had been re-admitted under one of my medical colleagues, and I was asked to see her on account of severe pain in her left side with repeated rigors, purulent sputum, and signs of consolidation at the base of the left lung, and a swelling over the region of the left kidney; the vaginal fistula had been closed for some time.

The diagnosis made was pyonephrosis and subphrenic abscess, and as the pain was severe and the temperature 104° F., immediate operation was undertaken. Per vaginam recurrent cancer could be felt in the pelvis.

Chloroform having been administered, the usual lumbar incision was made and the perirenal tissues found brawny and inflamed, and the convex border of the kidney bulged tensely in the bottom of the wound. A bistoury was inserted into the tense gland and a large quantity of pus was evacuated. A finger was then inserted and it was found that the cavity in the kidney communicated freely with a large abscess cavity behind the spleen. The question now arose whether I should rest satisfied with nephrotomy.

In favour of nephrotomy was the likelihood of the other ureter becoming obstructed by cancer or the kidney infected; on the other hand the operation has been undertaken to give comfort and not to prolong life except in comparative comfort, so we considered a urinary fistula in the loin contra-indicated; besides, there was a fear that the subphrenic abscess would not drain freely unless the kidney were removed.

Two other questions then arose: first, in an acutely septic area such as was here present ought the kidney be removed by the usual method, running the risk of cellulitis or injury of the peritoneum? Secondly, could ligatures be trusted to hold on a pedicle in face of such sepsis. Both these points were decided in the negative, and the kidney was removed by the subcapsular method of Ollier. This was used as a method of choice, as advocated by Tuffier, and not because it was impossible to do otherwise, which would seem to be the only indication recognised by most British writers. The kidney capsule was then drawn up and sutured around to the subcutaneous tissues of the wound, except at the upper portion, where a free opening was left into the subphrenic space. This method of dealing with the capsule made a neat, shallow cup in the loin with the pedicle safely within reach of finger pressure at the bottom, and thus secondary hæmorrhage need not cause alarm. The capsule was plugged every few days with iodoform gauze, and the cavity rapidly and soundly healed. The patient lived in comparative comfort for over four months, and then died from generalisation of the pelvic carcinoma, but without further urinary symptoms.

Post-mortem the left ureter was found completely cut across in the broad ligament and closed by cicatricial tissue; two silk ligatures were found embedded in the scar of the nephrectomy pedicle; the spleen was adherent behind where the abscess cavity had been; and nearly all the organs were infiltrated with carcinoma.

I bring this case forward as a means of making a suggestion that Ollier's operation might be the operation of choice in acutely septic cases, and not be relegated, as it seems to be at present, to the last line of defence.

Anatomical and Pathological Description, &c., of the Kidney Tumour from Case I.—The parts removed consist of 9 cms. (3½ ins.) of ureter leading to a kidney, the lower one-third of which appears normal, but the hilum and sinus are greatly distended above this by the emergence of a bunch of cysts; the upper two-thirds of the kidney seem to be dilated so as to form portions of a huge conglomerate cystic tumour. The mass is roughly trilobed; the upper and largest lobe is continuous with the kidney surface, is smooth and round and about the size of a large foetal head. From the anterior and lower surface of this springs another lobe, of about the same size but irregular in outline, which runs down on the antero-internal aspect of the kidney, and behind this is the third and smallest lobe, which is composed of the normal portion and part of the distended portion of the kidney. The ureter enters the hilum at the junction of the second and third lobes of the tumour. The whole mass weighs 3 lbs. 2 oz. (normal weight of kidney for a child of this age is 2 to 2½ oz.), is 56 cms. (22 ins.) in longitudinal circumference and 41 cms. (16 ins.) in transverse circumference. On

cutting the tumour open longitudinally we find that the pelvis of the ureter is large but not dilated, the lower one-third of the sinus of the kidney is somewhat dilated but contains a normal calyx, enclosing a fairly normal-looking papilla; a second calyx, 7 cms. long, runs to a small atrophied piece of kidney situated at the junction of the two large lobes, and a third calyx, 5 cms. long, runs to an atrophied papilla at the upper pole of the kidney, where it merges into the large cyst wall. The whole tumour is a congeries of cysts of all sizes, many of which open into one another.

Dr. H. C. Earl reports that the fluid in the cysts was of a light straw colour, was not albuminous and contained a fair amount of urea. The lower one-third of the kidney on section appears normal, except for very slight excess of cellular elements in the intertubular tissue; the middle one-third shows advanced sclerotic changes with commencing cyst formation in the tubes of all classes and in the capsules of Bowman, the arteries are not markedly thickened. The cysts in the tumour portion on section are lined with a very low columnar epithelium, which is evidently flattened out and tends to flake off; the walls are composed of fibrous tissue, and do not show any kidney substance between them. There are no intracystic papillary growths and no signs of activity of the epithelial elements. This case, therefore, seems to me to support the theory that these congenital cystic kidneys arise from foetal papillitis, and is interesting in that not only was it limited to one kidney, which is uncommon, but it was limited to only a portion of one kidney, which, as far as I know, is exceedingly rare.

In conclusion, I would like to express my indebtedness to Dr. de Rosario and Mr. Pringle for the notes of these two cases, and also for their assistance during the treatment of the patients.

THE TREATMENT OF CHRONIC HEART WEAKNESS BY BATHS AND EXERCISES. (a)

By NEVILLE WOOD, M.D., M.R.C.P.,
Honorary Physician Kensington Children's Hospital.

CHRONIC heart failure may be divided into four stages. First, a period when compensation is efficient; secondly, a stage when the heart works well under favourable conditions, but fails under those of medium stress; in the third period, the circulation is never quite efficient, and a slight stress may turn the scale; in the fourth stage, cardiac enfeeblement is extreme and irremediable. In the first stage, as a rule, no treatment is necessary except a general warning against overstrain. But occasionally there may be excessive arterial tension or excessive pulse rate. Such symptoms may well be treated by the method to be described. In the second stage I consider baths and exercises unequivocally to hold the place of pre-eminence. The earlier the treatment is begun in this stage, the greater the value of mechanical methods. In the third stage, mechanical methods tend to become useless, and finally are contra-indicated, while drugs may still retain their potency. The application of mechanico-balneological treatment by the family physician is

(a) Abstract of paper read at West London Medico-Chirurgical Society, January 2nd, 1903.

to be advocated because he is more likely to see the patient at the time when it is of greatest value. Baths and exercises may be said to conform more closely to Nature's methods, and, also, being more novel, to give scope for the beneficial influence of suggestion.

In endeavouring to assist an overtaxed heart, it is necessary first to lighten its load, and then to nourish its muscular substance and give the organ just as much work as it can beneficially perform. Where cardiac dilatation and arterial tension are prominent, relief must be afforded by arterial relaxation. In cases of less severity gentle stimulation may be adopted. These effects can be brought about by varying the temperature, composition and duration of the baths. A temperature of from 92° to 95° F. produces moderate dilatation of the vessels, with slowing of the pulse rate. When the temperature is lowered to 85° F. contraction of the peripheral vessels is caused, with great increase in the force of ventricular systole, the total effect being one of stimulation. The most useful constituents of the bath are the chlorides of sodium and calcium, and carbonic acid gas. The greater the proportion of these, the greater the stimulating effects. The duration of the bath should be longer when a sedative action is required.

When the first indication is heart relief, to a bath of fifty gallons five pounds of common salt should be added, and five ounces of calcium chloride, together with half the contents of one of Sandow's boxes. The bath is given at 95° F., and lasts about fifteen minutes; the patient then remains recumbent for two hours. After a few days the temperature is gradually reduced to 92° F., while the proportion of saline constituents is doubled. As the patient improves, stimulating treatment is introduced by lowering the temperature of the bath still further, and increasing the added solids. Very gradually the temperature of the bath is lowered to 85° F., and the strength of the saline solution increased to 6 per cent. Beyond this it is rarely necessary to go.

Systematic exercises are chiefly of service in the early part of Stage 2, or when relief has already been obtained from baths. They can be carried out without a specially trained assistant, by the following method:—Instead of the reversal of each exercise being a continuation of the initial part, an intermediate pause is introduced. Thus the first portion is made to last fifteen seconds, the part moved is retained in the position it has reached for five seconds, and the reversal is made to occupy fifteen seconds. In very muscular subjects extremely light weights may be placed in the hands. The pulse is counted immediately before the exercise, and again after three minutes have elapsed, by which time its rate should have fallen. This is the simplest test as to the prospective value of the exercises. During the exercises the breathing should be even and continuous. Instead of the Nauheim exercises, a system of weights and pulleys, may be used. At the end of a series of exercises it is well to examine the area of cardiac dulness and the position of the apex beat. If the area of dulness is enlarged, it may be taken that the dosage is too high. To sum up: the cases in which most benefit is derived are those of moderate dilatation, accompanied, and in great part caused, by general malnutrition. Cases presenting minor

degrees of arterio-sclerosis may be accepted for treatment. Supposed cardiac neuroses, such as tachycardia and arrhythmia, often do well. There are many failures among elderly persons. Cases in which the imagination alone is at fault should not be treated, as they certainly detract from the reputation of the method. As to whether treatment is most satisfactory at home or abroad, the advantages of the climate of Bad-Nauheim, the experience of the local physicians, and the current enthusiasms are counter-balanced by the shortness of the season, the poorness of the meat, and the usual foreign habits.

A SHORT CONSIDERATION OF OPERATIONS ON THE MASTOID AND ITS ANNEXA IN EAR AFFECTIONS.

By CHARLES GEO. LEE, L.R.C.P.LOND.,
M.R.C.S.ENG.,

Consulting Aurist to the Royal Southern Hospital, and Hon. Surgeon
Liverpool Eye and Ear Infirmary.

IN common with other departments of what may not incorrectly be termed regional surgery, the ear and its neighbouring structures have shared fully in the benefits that have naturally resulted from the more special attention that has of late years been devoted to their particular affections.

Many factors have in the course of years contributed to this, and we may do well to remind ourselves that the introduction of anæsthetics, the science of bacteriology, and the employment of asepsis, as well as the undertaking of cerebral surgery, each and all have combined to bring about the commendable advance in the treatment of aural disease, to which we have referred.

As exemplifying the state of knowledge in ear affections in the last generation, the following extract from Toynbee's "Diseases of the Ear" may not be uninteresting:—

"When the membrana tympani is evidently preventing the egress of matter, and when the irritation produced by the operation is not to be feared, there can be no harm in trying the effects of a puncture. Perforation of the mastoid process also suggests itself, and the operation may doubtless be performed in those cases where the matter is pent up in the cavity of the ear, and is causing such urgent and serious symptoms as are likely, if not relieved, to terminate in death. I have never performed the operation, but I should not scruple to do so in a case in which the life of the patient was threatened. Considering the large extent of the mastoid cells, it appears to me that the best plan of operating would be to trephine over the middle and posterior part of the process, and to remove a portion of bone three-quarters of an inch in diameter."

From this it is evident that the operation of opening the mastoid was scarcely entertained, or, at least, was only to be performed when the patient was almost *in extremis*; and, further, that should it have been done according to the directions suggested the lateral sinus would inevitably have been opened, an event which the writer apparently had not foreseen.

The following decade must have seen great development in the frequency and accuracy in performing this operation, for Politzer's classical work, published in 1883, contains a full description of the technique, and such indications of landmarks as to foreshadow the boundaries which were to be

so definitely and finally delineated by MacEwen in the future. While MacEwen's name will always remain as the most authoritative in indicating the definite spot for the opening in the mastoid, *i.e.*, within the boundaries of the supramental triangle, and while also his courageous attack on all possible foci for the propagation of pathogenic germs must always prove an example and incentive to his successors, it must, of course, be remembered that others had already been in the field, to wit, Stack and Schwartz; while working contemporaneously with MacEwen were A. E. Barker, of University College, and Arbuthnot Lane, of Guy's, both of whom contributed materially to the placing these operations on a sound and acceptable basis.

In addition to the above, and to others that should be mentioned, were this contribution in any way a history of the operations, the name of Charles A. Ballance has especial claims for notice. His papers on "The Conduct of the Mastoid Operation for the Cure of Chronic Purulent Otorrhœa" extend and amplify the work of those already named, and furnish an invaluable guide to the conduct of the most thorough operation that can probably ever be undertaken on this bone.

With all these authoritative encouragements to perform a radical operation for the cure of otorrhœa, it is not surprising that the procedure has very frequently been adopted; and it is indisputable that it has been done on occasions when a much simpler operation, combined with persevering and thorough local treatment, would have sufficed.

To substantiate this statement it will suffice to mention that it has become almost routine treatment to open the antrum in all cases of abscess behind the auricle occurring in the course of an otorrhœa. This treatment is probably due to the graphic pictures drawn by MacEwen of this condition. In many cases this is not only unnecessary but absolutely wrong, for it happens that the pus is simply a subperiosteal collection that has travelled back from the tympanum behind the cartilaginous meatus, and only requires a good incision (Wilde's), with drainage, to completely evacuate the abscess, and permit the integuments to resume their normal position, the substance of the bone never having been implicated in the attack. For the purpose of this argument it must be mentioned that even with the utmost circumspection and care, adjoining structures, more especially the portio dura, are not infrequently injured in the process of these so-called "radical operations." Indeed, if the term "radical" be used as a synonym for "curative," it would be better not employed, for an aurist of the widest experience and highest credibility assured the writer that many cases which had been subjected by a surgeon of great eminence to the radical operation subsequently came under his care for treatment of a recurring discharge.

When a grave operation is undoubtedly necessary, the question of differential diagnosis confronts us, and is often one of great difficulty. Who is acute enough to distinguish between a localized subdural abscess and a cerebral one? And can any observer say whether abscess in the brain may be single or multiple?

The following case will serve to exemplify some of these difficulties:—

Alfred P., æt. 5, was admitted under my care into the Liverpool Eye and Ear Infirmary on February 24th, 1899. He had a history of discharge

from right ear since infancy. The present acute attack commenced fourteen days ago, with sickness, headache, and some tenderness was noticed over the mastoid region. Two days before he was brought to the Infirmary he had general convulsive movements of the limbs, which were followed the next day by rigidity of left arm and leg.

When admitted the child cried out when touched or disturbed in any way. There was marked loss of power in left arm. The left leg was rigid, and patient was quite unable to move it. Abdomen retracted. Some slight tenderness over right mastoid, extending over same side of head. Pupils semi-dilated, reacted to light; there was no optic neuritis. Discharge of pus from right meatus. The tympanic membrane perforated. Temp. 100°; pulse 120; Resp. 32.

Feb. 25th.—Some stiffness of left arm. At 4 p.m. the mastoid was opened; on removing a thin shell of bone a large cavity was exposed, from two to three ounces of pus were evacuated. Overhanging bone was removed, and the cavity thoroughly curetted. Conjugate deviation of the eyes was noticed directly after operation, but this soon passed off.

On the 27th not much improvement from previous operation, and patient was more drowsy, answered questions more slowly; arm and leg the same. At 4 p.m. the skull was trephined over motor area; on opening dura about one and a half drachms of pus escaped. The brain was incised but nothing came away, no abscess found. During the following night much quieter, moved arm much better, leg remained as before.

March 1st.—Was now able to move both arm and leg freely, both wounds dressed, no pus from cerebral wound, a little from mastoid.

4th.—Very restless, screamed all night, pupils widely dilated, unable to move arm and leg. Temp. 99°. The child gradually got weaker, and sank on the evening of the 9th.

Post-mortem.—On incising the dura mater over the cerebrum, a large quantity of pus escaped from between the two hemispheres, and the whole external surface of the cerebrum was congested, while a thick layer of pus extended quite across from one hemisphere to the other. The interior surface of the right occipital lobe was necrotic, a large portion having sloughed away. Corresponding to the leg centre on the right side was a small superficial abscess; a little anterior and nearer the middle line a second and larger abscess. A small abscess was discovered on the anterior portion of right half of cerebellum.

The tentorium cerebelli was thickened and in places sloughing. No pus in cerebellar fossa, nor was there any on the cerebral surface of petrous. The posterior wall of mastoid was perforated and communicated with loculated pus between the tentorium and occipital lobe. Lateral sinus normal.

The recent records of the Royal Southern Hospital could supply more than one case almost identical with the foregoing, but their recital would only serve to unduly lengthen this article. Since then it would appear that the "radical" operation is not always final, and that our diagnosis cannot always be exact; we shall do well to thoroughly and independently weigh the particular symptoms of each case, and not permit ourselves to be unduly biassed in favour of some specific operation,

though it may enjoy the prefix of a name of high repute in surgical esteem.

We must only subject those patients to the so-called radical operation in whose case it appears probable that neighbouring and important structures may become involved.

For the future it must not suffice to undertake such an operation merely because there is a discharge which has existed for a long period; it is incumbent upon us first of all to try if a cure cannot be brought about by a more persevering and thorough local treatment, as suggested by Mr. F. Faulder White in his paper contained in the Transactions of the Sixth Otological Congress, held in London in 1899, and to reserve our operations for those cases in which such treatment has failed; or where fistulæ and sinuses in the bone exist; or again and finally, where such grave symptoms are so urgent as to permit of no delay in our attempting their relief.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, JANUARY 9TH, 1903.

MR. HOWARD MARSH, F.R.C.S., President, in the Chair.

MR. OPENSHAW showed a recent specimen of congenital hip, obtained from a girl, æt. 6, who died of bronchial pneumonia, which demonstrated the following conditions: The acetabulum exists. It is small, shallow and flattened, and is not filled up with fibrous tissue. The bone and cartilage beneath it are thicker than normal. The cotyloid ligament is well developed but is curved inwards towards the centre of the acetabulum, and it is this ligament which partially fills up this cavity. The capsule of the joint is attached to the margins of the acetabulum, it is constricted externally to this attachment so as to leave a small opening through which the finger could be passed into the acetabulum cavity. From this point the capsule is widely expanded, permitting the contained head of the femur to move freely about within it. The internal surface of the capsule is smooth and normal. The capsule itself is about normal in thickness. The ligamentum teres is represented by a thin band frayed out at its unattached extremity. It would seem to have been gradually thinned out and ultimately ruptured. The head of the bone is normal in shape with the exception of a small area of flattening at the lower end and back part. The neck of the femur presents no abnormality. The above appearance entirely accords with what Mr. Openshaw has found by operation. In his experience, in every case an acetabulum exists. It is small, shallow, and triangular. The cartilage forming its floor is thicker than normal. Over it the capsule is constricted so that the point of the forefinger is with difficulty passed down to the acetabular surface. In Mr. Openshaw's opinion, the head of the femur before the age of three is normal. It then becomes flattened at one part. The flattening gradually extends over the whole surface, and thus the head of the bone becomes deformed and as the result of subsequent osteo-arthritis change, ultimately disappears. The ligamentum teres he has considered hitherto to be absent but, he adds, it is quite possible he may have overlooked a thin flaccid band such as exists in the specimen which he submitted. In many cases the neck of the femur is curved, and this is especially the case on one side in cases of double dislocation. The curve presents usually a concavity anteriorly, so that when the patella is directed forwards the head of the femur looks forwards as well as inwards, instead of directly inwards. Various groups of muscles are more or less contracted in this condition. Thus, the adductors are always considerably shortened, the

tensor vaginæ femoris, sartorius, and the front part of the gluteus minimus and medius are nearly always somewhat contracted, and the hamstrings occasionally. The iliacus and psoas tendon, in consequence of displacement of the femur upwards and outwards, pass round the anterior inferior spine, outwards and backwards, and in some cases even upwards to the small trochanter; thus, in severe cases, the pelvis is partly suspended upon the psoas tendon. The muscles of the legs generally on the affected side, are somewhat wasted, and the pelvis is apt to be flattened and oblique upon the affected side, and lastly, in consequence of the dropping of one side of the pelvis in unilateral cases, scoliosis is subsequently developed. In bilateral cases lumbar lordosis exists from the first. He advocates one or two methods of treatment. Reduction of the shortening by tenotomy and extension and then reposition, so-called, of the head of the bone by manipulation as practised by Lorenz; or (2), the manufacture of an acetabulum by the open method after it has been made possible to replace the bone by manipulation. As the result of the experience of some twenty cases treated by the first method during the past six years, he considered, first, that reposition within the joint was an impossibility, and secondly, that redislocation is exceedingly common. He strongly advised the two methods combined, and showed two cases where he had operated with excellent results. He pointed out that if the shortening were overcome first the shock of the operation was slight and a fatal result need never be anticipated, and that if an open operation were advisable that of deepening the acetabulum was the only one to be entertained.

Mr. JACKSON CLARKE remarked that the specimen shown by the author resembled very closely what he had found in the new-born infant. He had operated in about twenty cases by the Lorenz method, and in only one instance had he failed to obtain any result. In some of the cases it seemed to be very nearly reposition allowing for the arrest of growth and consequent inevitable shortening. In the one case of failure the child was suffering from spastic paralysis, which had not been recognised and could not support the abduction of the limb, so that the failure was explained.

Mr. NOBLE SMITH pointed out that Lorenz, who had largely contributed to the introduction of the open method, had finally abandoned it. His own experience, consequently, had been chiefly manipulative. He advocated dividing the operation into two stages, by which means he believed the amount of force required to effect replacement was much reduced.

The PRESIDENT urged that in discussing this question they should bear in mind the various facts worked out in connection with its pathology, and he called attention to a very valuable paper contributed by Dr. Burghard to the *British Medical Journal* in 1891, giving the results of his very exact anatomical investigations. That author referred to the hour-glass contraction of the capsule, which offered an obstacle to reduction. The head of the bone was often in an upper pouch of the capsule, above the acetabulum proper from which it was shut off by an isthmus. Mr. Burghard found that the division of the ilio-psoas tendon allowed of the easy replacement of the head of the femur. He suggested that a committee should be appointed to investigate and report on the subject, but he admitted that such a committee would be confronted with the difficulty of deciding what the condition had been before operation, so that it would be desirable for them to watch cases from the beginning. He himself was not prepared to assert that in the author's cases the head of the bone had really been returned into the acetabulum proper. He suggested that part of the extra stability of the joint might be due to the extensive cicatricial contraction which must follow such great interference with the structures in the neighbourhood of the joint. He mentioned that he had once been called to see a young woman, who turned out to be the very patient whose case had been extensively reported as an instance of cure by long extension at the hands of the late Mr. William Adams,

but, as a matter of fact, it was clearly a case of unaltered congenital dislocation.

Mr. OPENSHAW, in reply, pointed out that it was not only the psoas-iliac tendon that was at fault, the capsule as a whole being contracted.

Mr. GOODALL read notes of

A CASE OF HÆMORRHAGIC TYPHOID FEVER.

which will be found on page 25.

Dr. LEE DICKINSON referred to two cases reported by American authors, and mentioned one of the same kind which he had observed at St. George's Hospital. The patient was a woman, æt. 29, who bled from almost every mucous surface. He recalled the statements recently brought by Professor Wright before the Royal Medical and Chirurgical Society to the effect that in the acute stage of typhoid fever the coagulability of the blood was hindered, whereas in the latter stages it was abnormally increased, thereby disposing to the formation of clots. The observer also stated that alcohol diminished the tendency of the blood to coagulate, and added that in both the American cases the patients were confirmed alcoholics.

Dr. CORDE ADAMS mentioned a case he had observed during an epidemic in North London. The patient developed patches of purpura the size of a shilling over the limbs and trunk, but she recovered. There could be no question of under-nutrition or alcohol in this case.

Mr. GOODALL, in reply, observed that such cases were fortunately rare, seeing that they usually proved fatal. He thought alcohol could be excluded in his case, and it was not given medicinally until long after the symptoms had developed.

GENERALISED MILIARY TUBERCULOSIS WITH ACUTE SYNOVITIS.

Dr. H. D. ROLLESTON read the notes of the case of a man, æt. 52, who was admitted to St. George's Hospital after two weeks' illness, with a temperature of 103°, in a semi-delirious condition, and with painful and swollen joints. At first, under salicylates, the pain diminished and the temperature fell, but very shortly this effect was lost. There were no physical signs of any importance, except widespread tenderness, and the patient became more prostrate and delirious, and died five days after admission. The diagnosis during life lay between generalised tuberculosis, severe typhoid, and some pyæmic state. The general condition suggested tuberculosis, but the arthritic manifestations made some other form of hæmic affection more probable. At the autopsy, except for synovitis, nothing definite was found; no tubercle could be seen. Pieces of the lungs and spleen, after being hardened, were seen, even by the naked eye, to be riddled with miliary tubercles. The association of generalised tuberculosis with acute synovitis of several joints was a very rare condition, and might lead to an erroneous diagnosis of acute rheumatism. Another point of clinical interest was the widespread tenderness.

Dr. KINGSTON FOWLER mentioned the case of a girl who had a cavity in the lung who suddenly developed acute synovitis of the wrist-joint. He thought that in the author's case there must have been some other concurrent affection, because if the joint affection were really due to tuberculosis one would expect to meet with it more frequently.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

At a meeting held on FRIDAY, JANUARY 2ND, 1903, the President, Mr. RICKARD LLOYD, in the chair, Dr. NEVILLE WOOD read a paper on the "Treatment of Chronic Heart Weakness by Baths and Exercises in Family Practice," which will be found on page 30.

In the discussion following the paper, Dr. C. W. CHAPMAN observed that patients suitable for Nauheim treatment were: 1. Convalescents from acute cardiac disease after prolonged rest had been taken. 2. Patients presenting cardiac symptoms, but devoid of organic disease. 3. Patients in the early stages of cardio-vascular degeneration. 4. The large class

known as neurotics. The treatment was contra-indicated in: 1. All advanced cases of heart disease. 2. Marked cases of cardio-vascular disease, especially with albuminuria. 3. The labouring classes, who require rest above all things.

Dr. A. MORISON remarked that had the limited scope laid down by Dr. Wood always been observed, less discredit would have been thrown upon the Nauheim treatment. Although he believed that quite as good results could be obtained from drugs and hygienic measures, yet baths and exercises were often useful in the initial breakdown of compensated hearts, or in those regaining compensation.

Dr. ALDERSON instanced himself as showing the advantage of exercise in commencing cardiac failure. He had derived great benefit from cycling, although he had been told previously that he showed signs of cardiac weakness.

Dr. RICE OXLEY asked whether graduated walking was used in the Nauheim treatment.

Dr. NEVILLE WOOD, in reply, observed that nothing he had said had been traversed. In answer to Dr. Rice Oxley the terrainkür was being less and less used, while the so-called Schott exercises seemed to be less esteemed than formerly. The systematic use of the cycle was gaining ground.

Dr. OTTO GRÜNBAUM read a paper on the "Value of the Examination of the Blood as an Aid to Diagnosis and Prognosis." After showing diagrams illustrating the various types of leucocytes, Dr. Grünbaum dealt with the organisms which cause suppuration. Many, but not all, pus-producing organisms, cause leucocytosis, but the toxins of some organisms which do not produce pus may lead to the same condition. In appendicitis, if the symptoms are not definite in showing the presence of pus, the enumeration of the white cells may be of great assistance to the surgeon. If 30,000 were found instead of the normal 8,000, it would be very probable that pus was present. After operation for an abscess, an increase in the number of white cells would be a sign of inefficient drainage. An increase in the number of white cells accompanies many forms of malignant disease, and nearly all fevers. But when pus is present there is generally also an increase in blood platelets and in the amount of fibrin. In certain doubtful cases of syphilis the method introduced by Justus may assist the diagnosis. Justus found that in this disease as soon as the lymphatic glands are affected the intravenous or intramuscular injection of mercury causes the disintegration of a considerable number of red cells. This disintegration is detected by estimating the hæmoglobin of the patient's blood. When the reaction to the injection is positive, a fall of from 10 to 20 per cent. of hæmoglobin will be noted within forty-eight hours, returning to the normal a few days later. After a few injections the percentage ceases to fall, and ultimately may actually increase. The reaction does not occur when mercury has been given by the mouth. The diagnosis between hysteria and disseminated sclerosis may be assisted by estimating the quantity of cholin in the blood. Recently Halliburton and Mott have shown that when nerve cells degenerate the increase of cholin in the blood may be so marked that it can be isolated from 10 c.c. of blood. When, therefore, a recognisable amount of cholin can be isolated from the blood we may conclude that active degeneration of nervous matter is taking place. Cryoscopy, or the estimation of the freezing point of blood, may be of use in informing us as to the state of the kidneys. In renal disease the quantity of salts and of urea in the blood is greater than normal. The greater the amount of these substances in the blood the lower will be its freezing point. The average freezing point of normal blood is 0.56. If it falls to 0.6, or lower, grave doubt as to the efficiency of the kidneys must be entertained. With regard to the agglutination reaction in enteric fever, the method is often discounted by carelessness. Serum from the patient ought to be diluted fifty times with normal salt solution, and a fresh culture of actively motile bacilli added. If the reaction is positive,

clumps ought to be formed within the hour, and no motile bacilli should then be present. Agglutination without paralysis of the flagella may occur in other conditions, such as jaundice and pyæmia. A negative reaction does not contra-indicate enteric fever. The examination of the blood for micro-organisms is still in the experimental stage. When the preparation of the antitoxins has been improved, the isolation of organisms from the blood may be possibly of vital importance. The examination for parasites can be carried out efficiently in fresh films of blood kept at 37° C. Dr. Grünbaum pointed out that, except in leucæmia and certain parasitic diseases, no diagnosis could be founded on the examination of the blood alone.

Mr. R. LLOYD asked in what stage of syphilis Justus' test could be applied. Its importance would be chiefly in the primary stage.

Dr. WHITFIELD had used Justus' test in a number of cases of syphilis, and except in a single undoubted case of syphilis had never found it fail. He instanced a patient in whom the symptoms were so slight that diagnosis was not easy. Finding a drop of 12 to 15 per cent. in hæmoglobin in twenty-four hours after inunction he adopted the usual treatment. The man had ultimately a very severe attack. The test is only of use in cases which have reached general constitutional infection, and have not recently been under treatment with mercury. Dr. Whitfield also advised that the delicate manipulations required in hæmatology should be carried out entirely by experts. Without special education many errors may be due to faulty technique.

Mr. MCADAM ECCLES asked where the increased number of leucocytes is derived from in suppuration. Would the entrance of a toxin into the blood cause that increase apart from the actual local collection of cells found in the abscess? In some cases of rapid gangrene of the appendix without suppuration there appears to be a more marked leucocytosis than even when there is a distinct collection of pus.

Dr. LONGRIDGE had investigated hæmatologically some fifty cases of appendicitis. He had invariably found leucocytosis when the condition of the appendix called urgently for operation. The highest leucocytosis was in the gangrenous cases, and next in those with a large extent of peritoneum involved. He would regard leucocytosis as an indication of toxæmia. In only one case with a perforated appendix and general septic peritonitis had he failed to get a very high leucocytosis.

Dr. GRÜNBAUM said that most of the points raised had been answered by Drs. Whitfield and Longridge. In leucocytosis the leucocytes which appear in the blood are supposed, in the first instance, to migrate from the bone marrow.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD (at 11, Chandos Street, London) FRIDAY, DECEMBER 12TH, 1902, MR. H. H. TUBBY, F.R.C.S., in the Chair, when

TUBERCULOUS PERITONITIS

was discussed.

Various portions of the subject were introduced by different speakers.

Dr. CAUTLEY opened the discussion and dealt with a paper on its "Etiology," which appeared in our issue of December 31st, 1902. Various questions were lightly touched upon, from the predisposition to invasion by the tubercle bacillus to the special modes of entrance into the peritoneum. The speaker remarked that since the tubercle bacillus is so extremely common, a vulnerability to the microbe must play as important a part as exposure to the possibility of infection. To fortify the body therefore by good food and clothing was as important or possibly more important, than war against the bacillus outside the body. How far peritoneal tuberculosis was due to invasion by the bacillus of bovine tuberculosis Dr. Cautley thought still to be an open question.

Dr. THEODORE FISHER (Bristol) followed with a few

facts in connection with the "Morbidity Anatomy." Eighty cases of tuberculosis of the peritoneum, which clinically had been cases of abdominal disease, had been analysed. These had been collected not only from the Bristol Royal Infirmary, but, through the kindness of Dr. Lauriston Shaw and Dr. Lazarus Barlow, also from Guy's and the Westminster Hospitals. At the time of death the great majority of cases proved to be of the adhesive variety. In eight cases—*i.e.*, in 10 per cent. of the number, suppurating caseous masses had opened into the intestines and in another five cases perforation of intestinal ulcers had occurred. Intestinal ulcers were present in about half the cases. In seventeen cases the lungs were free from disease, and in seven others tubercles were limited to the pleura; but in the remainder there was chronic disease of the lungs, which, however, was generally limited in character. There were five cases of tuberculous disease of the Fallopian tubes in adult females, but apparently these tubes were more commonly affected in children.

Dr. CHAFFEY (Brighton) made a communication upon the same subject. He had analysed 118 cases of tuberculosis in children, and found tubercle of the peritoneum in 45. Of these 45 cases, in 22 the disease was chronic. In 13 of these 22 cases intestinal ulcers were present, and in 17 the lungs were diseased. In the 23 cases of recent tuberculosis of the peritoneum the lungs were affected in every instance.

Dr. JAMES BARR (Liverpool) dealt with the "Diagnosis," his remarks being embodied in a paper which appeared in our issue of December 24th, 1902, and in which it was shown that the most striking feature is swelling of the abdomen.

Dr. GEORGE CARPENTER referred to many cases which had been under his own care, and showed sketches illustrating what had been felt on palpation of the abdomen. In many of the slighter cases the true nature of the disease could be recognised only by a rectal examination.

Dr. J. PORTER PARKINSON remarked that on looking over the notes of 22 cases he had been struck with the somewhat rapid onset. The average history of 19 cases extended only over three and a half weeks. Dr. Parkinson thought the occasional presence of enlarged veins over the upper half of the abdomen was worthy of note and suggested some interference with the portal circulation. An interesting case of colloid carcinoma of the peritoneum occurring in a girl, *æt.* 12, was referred to. Clinically it had been impossible to distinguish it from a case of tuberculous peritonitis, but a nodule removed at the time of the exploratory operation revealed the nature of the disease. Of Dr. Parkinson's 22 cases 14 were under the age of four years.

Dr. G. A. SUTHERLAND then read a paper upon the "Prognosis of the Disease," which we hope to publish in our next. Forty-one cases treated at the Paddington Green Children's Hospital had been examined. Of these 41 cases 29, or 70 per cent., recovered, 11 died, and 1 was unrelieved. Of the cases treated medically, 22 recovered and 4 died; of those surgically treated, 7 recovered and 7 died. The word "recovery," it was pointed out, did not by any means necessarily mean permanent recovery. The 29 cases were, however, well when looked up after leaving the hospital, periods having elapsed varying between 3 months and over 6 years. Dr. Sutherland afterwards briefly dealt with the various types of tuberculous peritonitis, referring to features which might be considered to be of good or unfavourable omen. Some complications, such as intestinal ulceration, extensive caseation of mesenteric glands, and localised suppuration were, as might be expected, of serious import. In cases in which marked pulmonary lesions prove to be present the prognosis is unfavourable, but when disease is limited to the pleura the outlook is not necessarily bad.

Dr. ROBERT HUTCHISON thought a clear distinction must be drawn between those cases in which tuberculous peritonitis is primarily in the abdomen and remained there, and with those in which it is merely a

part of wide-spread tuberculosis. With regard to the ascitic form of the disease, he thought it probable that a simple chronic peritonitis may exist. It did not necessarily follow that all cases of peritoneal effusion in children, when the fluid had disappeared, had been tuberculous in nature.

A communication from Dr. JAMES CARMICHAEL (Edinburgh) stated that in 48 of his cases of tuberculous peritonitis there had been 9 deaths. In 13 of the cases of recovery the patients had been kept under observation for a prolonged period and remained in perfect health.

Dr. LEONARD GUTHRIE then read a paper on the "Medical Treatment." The paper dealt largely with the relative value of medical and surgical treatment. It was not considered that surgical treatment is of more value than medical. He mentioned that it had been suggested the cases which recovered under medical treatment were not tuberculous at all. Dr. Guthrie thought it a little hard that the physician should be right when he called the surgeon in, but wrong when he did not. With regard to medical treatment it was a matter for opinion whether such drugs as mercury or arsenic do any good. Medical treatment is in the main confined to treatment of symptoms; and after recovery to attention to hygiene. While, however, medical treatment is in the main symptomatic, it is doubtful whether the value of surgical treatment is more than mythical. The surgeon, like an ancient Etruscan *Horuspex*, after opening the abdomen, merely gazes at the victim's entrails and discovers propitious omens for the future. Yet possibly the letting out of fluid may do good, but there is no reason why simple puncture should not answer quite as well.

Dr. CHRISTOPHER HAYWARD (Manchester) thought tonic treatment was good, and he considered a combination of bromide of arsenic and bromide of gold valuable in chronic tuberculous affections.

Mr. WATSON CHEYNE stated that if the physicians had discovered that tuberculous peritonitis is a curable disease they should thank the surgeons for the discovery. Six years ago he had been unable to find any statistics indicating the curability of the disease. When the physician had given up a case of tuberculous peritonitis as hopeless he brought it to the surgeon, and to the surprise of both, perhaps, the case often recovered. Since it was the worst cases which were brought to the surgeon the statistics of medically-treated cases and those operated upon could not be compared. In spite of the change of front of these physicians, Mr. Cheyne was not yet going to admit that laparotomy is of no value in tuberculous peritonitis.

Mr. F. C. ABBOTT thought that the cases which were most benefited by operation were those which commenced in the Fallopian tubes or ovaries. Most statistics showed the majority of fatal cases to be in males, whereas most cases which were operated on and recovered were in females.

Mr. R. H. A. WHITELOCKE (Oxford) thought with Mr. Abbott that the cases of tuberculous peritonitis which arose in the Fallopian tubes were the most suitable for operation. He gave some details of the way he treated these cases.

ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST,
JANUARY 8TH.

DR. JOHN CAMPBELL, President, occupying the
Chair.

THE following were elected Fellows of the Society:—Drs. G. R. Lawless, Armagh; J. C. Sugars, Dunganannon; Jas. Craig, Londonderry; John Wilson, Castle Blayney; George Waring, Glenavy; Robert Henry, Comber; George St. George, Lisburn; D. S. Browne, Belfast; Robt. Magill, Newcastle; D. C. Kirkhope, Belfast; and Martha Adams, Lurgan.

Dr. LYNASS showed "a curious case" of what looked like a new growth in the upper jaw of a boy, *æt.* 7. The patient was strumous and deficient men-

tally. The case seems to correspond with one described by Erichsen as simple hypertrophy of the gums.

Dr. BRIAN O'BRIEN showed a child with an interesting congenital deformity of the foot, with radiographs.

Mr. ANDREW FULLERTON showed a child from whom the clavicle had been removed for necrosis, and a tabetic patient with great enlargement of the leg due to callus from a spontaneous fracture.

Dr. JOHN MCLEISH showed a cardiac case.

Professor LINDSAY opened a discussion on "The Difficulties of the Medical Examiner in Life Assurance Work." He dwelt at some length on the general attitude of the medical examiner, and the necessity of his observing the golden mean between negligence on the one hand and over-examination on the other. It is no part of the examiner's duty to act as detective. After these more general observations he proceeded to deal with particular difficulties, and gave his views regarding many of them.

Dr. CALWELL emphasised the necessity for practical common sense in life assurance work. He discussed several difficulties, including those where the candidate has an intermittent pulse or a chronic hoarseness.

Dr. MCQUILTY dwelt specially on the question of heredity and tuberculosis, and on albuminuria.

Sir WM. WHITLA criticised American proposal forms, and pointed out that their great detail was due to the fact that the American societies do not trust their medical men, but simply let them collect information on which the medical officials of the societies form their own judgment.

Dr. NELSON made some remarks on the question of ear disease and insurance.

At the conclusion of the discussion Sir WM. WHITLA announced that he had received a cheque for £100 from Professor Redfern, to be used in any way he might think fit for the benefit of the Ulster Medical Society. He proposed to hand it over to invest, to form the nucleus of a fund for the extinction of the ground rent. Much pleasure was expressed by the members, most of whom were in past days his pupils, at Professor Redfern's generous gift.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 10th, 1903.

EARLY DIAGNOSIS OF PHTHISIS.

ONE of the questions creating the most interest at the present time is that of the curability of consumption. It is admitted by all that that hitherto hopeless malady is amenable to treatment under certain conditions when recognised in its incipient stage. Some go further and pretend that phthisis, in any of its stages, provided the lungs be not utterly destroyed, can be cured, or at least the morbid process may be arrested. In any case the chances are naturally infinitely greater where the malady is detected at its earliest stage. Professor Courtois-Suffit made an exhaustive study of the early diagnosis of pulmonary tuberculosis, which he has published in one of the medical journals, and of which I give a brief résumé.

CLINICAL SIGNS.

Progressive wasting, a very important sign in children—general fatigue, depression of strength, neurasthenia. Frequently is added a pyretic tachycardia and urinary troubles (in complete evacuation of the bladder), slight incontinence; thoracic pain, especially under the clavicles and the scapula, caused frequently by dry pleurisy.

Frequently also is found a pain remarked by Cater, and produced by pressing on the pneumo-gastric

nerve at the base of the neck. Digestive troubles exist frequently. Almost all the patients complain of a little dry cough, while the voice is more or less hoarse. Hæmoptysis is frequently the first manifestation of the malady; it is generally very slight and may not return for several months, and, perhaps, never.

The examination of the patient will reveal the following signs:—Frequently unilateral dilatation of the pupil, remarked by Destrée and Harrington; red gum line noticed by Thompson, and considered as a very important sign by Caudressen, as he found it in sixty-nine true and twenty-three suspicious cases. The patient being undressed, the coloration, rarity, or, on the contrary, abundance, of hair will be remarked, depression of the scapular fossæ, and a flattening of one side of the thorax.

There is a sign which should be always looked for: it is that which Boix described under the name of scapulo-thoracic amyotrophy or atrophy of the fleshy dome covering the apex of the lung affected, and interests all the muscles of the region—trapezium, deltoid, pectoralis, and scapular muscles.

Auscultation and percussion were particularly studied by Graucher and Fernet. The former reveals an inspiration, rough and grave, which, according to M. Graucher, is pathognomonic. It was due to the diminished calibre of the respiratory ducts and the roughness of their walls. Expiration is rude and prolonged, exceeding frequently the duration of inspiration.

In the studies he made on the phenomena of auscultation observed in incipient phthisis, M. Fernet drew attention to three distinct points, which were the apex of the lung, and more especially in the supra-spinous fossa and the groove between the pectoral and the deltoid muscles, furnishing the signs above indicated; the inter-scapular space on the affected side (dulness and tubular snuffle), and, finally, at the base of the lung, dulness and subcrepitating râles.

Examination of the head reveals tachycardia, which is always a bad sign, even if no other plausible predisposing sign of tuberculosis can be found.

The fever in infected consumptives might always attract the serious attention of the medical attendant. According to M. Chrétien it presents three clinical types. The first is that which comes under the name of subjective fever. The patients do not present any rise in the temperature, but complain of malaise, lassitude, and depression every evening towards five o'clock.

The second type is the subfebrile described by Strempel. It is frequent. The temperature of the patients is normal in the morning, but rises one or two degrees towards evening.

The third and last type is characterised by continued fever, with oscillations varying but slightly.

The early diagnosis of tuberculosis, concludes M. Courtois-Suffit, is a difficult problem to solve in a large number of cases, and up to the present day we do not possess any pathognomonic sign on which we can positively make our diagnosis. Yet by careful study of the predisposing signs and the general symptoms, and in particular of the temperature, we can arrive at an almost precise conclusion and institute treatment accordingly, and furnishing to the patient the best chance of cure.

DR. H. F. MARLEY, of St. Issey, Cornwall, has been presented with a purse containing a hundred guineas and an address testifying to the admiration and affection of the inhabitants of the district.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 11, 1903.

At the Société de Charité Physicians Hr. Mendel related a case bearing on the

ETIOLOGY OF CHRONIC NEPHRITIS.

It was that of a young girl suffering from chronic nephritis who was suddenly attacked with a rigor followed by high fever. The autopsy showed a splenic tumour, swollen bronchial glands in which, as well as in the ascitic fluid and kidneys, streptococci were present in pure cultivation. The speaker considered the old streptococcal thrombi in the glands to be the starting point of the bacteræmia and the cause of death.

He then related a case of

NEPHRITIS IN PREGNANCY WITH ECLAMPSIA.

The patient was a girl, æt. 17, who was admitted with œdema of the right labium and purulent vagina discharge. She was seven months' pregnant. After a short aura eclampsia came on. She was delivered of a macerated fetus. Streptococci were found in the vaginal discharge, and also in the sputum. The speaker discussed different theories of eclampsia, and expressed the opinion that in his case it was caused by the streptococcal infection, the primary cause of which was the production of toxin in a chronically inflamed uterus.

Hr. Michaelis observed that bacteria were no rarity in the kidneys; they were present in a third of the cases in typhoid, and were also frequent in scarlatina and diphtheria. In regard to the second case, he thought it very improbable that the eclampsia was set up by retention of toxins.

Hr. Senator remarked that bacteria were rarely present in pure diphtheritic nephritis. He and Fürbringer held this nephritis to be caused by toxins. As regarded the eclampsia, he pointed out what had been shown by Zuntz, viz., the special excitability of the brain in pregnant women.

ADRENALIN.

Adrenalin, according to Dr. E. Hartmann (*Kon. Bl. f. Sch., Aertze*), is an extract of the suprarenal capsule of oxen. Wherever it comes, it sets up a transient acceleration of the circulation which is harmless. The function of the suprarenal gland was a double one: it furnished an internal secretion, the aim of which is to neutralise poisonous tissue-change products. Animals from whom the glands were removed died with symptoms of acute poisoning. A material was also prepared in the glands, which preserved the normal tone of vessels. Injection of the juice of the organ into healthy animals set up an increased resistance in the vascular system, particularly in the capillaries. In Addison's disease organotherapy frequently brought about a passing improvement. Last year Dr. Takamine, of New York, prepared a crystalline body from the glands of oxen which he called adrenalin. The crystals readily form soluble salts in combination with acids. In commerce the preparation has been brought out as a 1 per 1,000 solution of adrenalin hydrochlorate in physiological saline solution. If the skin of the arm is painted with this 1 per 1,000 solution, in the course of one or two minutes it becomes bloodless from contraction of the capillaries and remains in this state for two hours. Adrenalin allows the performance of all kinds of operations on the nose where before they were not practicable on account of the bleeding, but as the mucous membrane does not become anæsthetised, cocaine

must also be used. The writer generally adds a few drops of the adrenalin solution to a 20 per cent. cocaine solution, and paints the mixture on two or three times at intervals of two to three minutes. If the artificial anæmia required be very marked, he dissolves the cocaine powder in the adrenalin solution. The bloodlessness of the mucous membrane lasts from one to two hours, when a hyperæmia of reaction comes on. He advised it also in local suppuration in the nose and in empyema of the sinuses. In obstinate epistaxis it does not always act promptly. Painted on the epiglottis it quickly reduces swelling. Catheterisation of the Eustachian tube is rendered easier by preliminary painting with it, and polypi of the middle ear are shrunk by application of it so that they can be the more readily removed.

At the Medical Society Hr. Grawitz showed a case of so-called

TROPHONEUROSIS.

The patient was a girl, æt. 17, of healthy parentage, who had always been healthy, and who, eight months previously, was attacked with general disturbance and pain in the left leg, and simultaneously with this it became red, the redness advancing from below upwards. When she was admitted into the Charlottenburg Hospital six weeks ago there was redness of the whole leg and considerable tenderness on touch. Within a few days a considerable atrophy of the whole left lower extremity developed, so that the circumference of the thigh was 4 c.c. less than that of the right side. There was no infiltration of soft parts, and no stasis, and blood taken from the affected limb was exactly like that taken from the patient's arm. The case was one of simple atrophy of the skin and ectasy of the veins, the walls of which appeared to have become atrophic. Otherwise the nervous condition of the patient was good. He had not been able to discover any description of an analogous case. He considered it to be a trophoneurosis, the remarkable feature of which was its acuity.

BRÖSE'S METHOD OF EXTIRPATION OF THE MAMMA.

In non-malignant cases, in order to preserve the normal appearance of the part as much as possible, Hr. Bröse was in the habit of making his incision in the fold of skin below the breast, dissecting the skin up and removing the organ. He then replaced the skin. It was remarkable that the empty pocket of skin became so filled up with the fat that the absence of the gland was not noticeable to the eye.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 10th, 1903.

THE PROPHYLAXIS OF TUBERCULOSIS.

It may be remembered that some time ago the Gesellschaft appointed a committee from their body to investigate, and, if possible, formulate a few simple rules for the guidance and prevention of tuberculosis. At this juncture Sternberg gave a résumé of the committee's labours and expressed a desire to read a summary of their report, which he said might be properly divided into four sections. The first section was devoted to the education of the people and explanations to teachers and philanthropists in the guidance of such a disease. They suggested circulars and placards as well as lectures and university courses to further education on the subject.

The second section was devoted to the consideration of disposition and hygienic attention during the school period, with suitable localities during holiday time

where exercise could be taken. They also recommend convalescent homes in the neighbourhood of hospitals and reformation in the building of workmen's houses, which ought to be more sanitary and commodious. The walls of the school should be done with paint or lime for better and more effectual cleansing; this precaution should be also extended to workshops, &c. Greater attention should be given to public buildings and meeting places.

The third section deals with the prevention of infection, and recommends spittoons in all suitable places; notification of tuberculous disease and removal to hospital where expedient, more especially if the home be unhealthy. Disinfection of rooms where patients have been confined or die, railway trains and rooms in the neighbourhood of health resorts, as well as prisons, asylums, children's homes, and all such public institutions.

The fourth section treats with the diagnosis and treatment of tuberculosis. In the first part they recommend places where the sputum of the poor can be examined without cost. Such institutions should have conveniences for treating the infected, and if old and infirm, properly caring for them. In the discussion that followed Lang thought that sea hospitals and lupus institutions should be erected without further delay. Isenschitz asked if the committee had taken into account the vaccinating of tuberculous cases, or if they had considered the danger of the milk from cows?

Winternitz could hardly agree with the enforcing of many of the rules, as it was not yet clearly proved that the infection was directly transmitted from person to person.

OSTEOMALACIA OR ANÆMIA?

Jaksch brought forward another case, that of a man, *æt.* 26, in an extreme state of anæmia. According to his own story, he was taken ill about six months ago without any apparent cause. No other pathological change can be discovered beyond the anæmia. It may be of importance to note that the patient was a miner and was working in the Bremberg mines, in Hungary, where *anchylostoma* abound. With this presumption in view the stools were carefully examined. Extract of male fern was given in conjunction with bitter waters. The stools were found to contain worms and other helminthic products, together with blood. Cultivations were made with distilled water and kept at a constant temperature, which had the effect of developing the worms. The ova went on to cleavage, and formed embryos that resulted in larvæ. These facts led to the presumption that he had been infected with these larvæ in the water, thus producing the debility and anæmia from which he was suffering. Subsequent examination of the stools revealed an absence of blood, blood pigment and Charcot-Leyden crystals.

The blood of the patient, considering his appearance, was less altered than might have been expected. The red corpuscles were 3,476,000 per cm., while the white were 12,000 with 6.3 of hæmoglobin. There was only slight poikilocytosis, but a great increase in the eosinophile cells. These facts correspond with the opinion formed by Lusano, who considers that the *anchylostoma* forms a ferment that acts as an irritant in the internal organs, forming polynuclear eosinophile leucocytes. The patient at the present time shows no other morbid condition beyond this interference with the metamorphosis.

Hans Chiari recalled the opinion expressed by Looss, of Brazil, who found the transition of the *anchylostoma* embryos was so widely diffused in the

organism that they could often be found under the skin.

Schwartz contended that the patient Jaksch had shown was suffering from nothing beyond osteomalacia. His skiagram clearly pointed to osteo-diathe-
 thesis, as seen in the long bones where spontaneous fracture had taken place and recovery had been effected. He would specially point out in the skiagram that the callus around the fracture was extremely slight. This absence of the lime salts was a strong point in his argument, and he regarded it as analogous to one of Pribram's cases of typical osteomalacia. He criticised the skiagrams, which, to his mind, demonstrated the osteomalacia. Jaksch, in reply, declined to admit Schwartz's arguments in view of the absence of the most characteristic symptoms of osteomalacia, pelvic changes, &c.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

REMOVAL OF COMPLETE UPPER EXTREMITY.—Mr. CARLESS operated on a woman, *æt.* 55, who had been sent to the hospital with a tumour of the humerus; this had been in existence for some months, and a spontaneous fracture of the bone had occurred some weeks previously. The tumour was the size of a coconut, and was situated near the upper end of the bone, the movements of the shoulder-joint being restricted. It was pointed out that the age of the patient was a little more than that at which sarcoma usually appears, and at his first examination of the case Mr. Carless had suggested the possibility of the growth being secondary to some other cancerous or sarcomatous deposit in some other part of the body. On a more complete examination it was found that the woman had a vaginal discharge, and an indefinite lump had been felt in the hypogastrium; moreover, on skiagraphic examination certain rounded shadows had been detected in the lungs which the skiagrapher had first thought to be due to buttons on a woollen jacket, but it was found that they were not of this nature but due to some deposit within the body. As soon as the patient was anæsthetised, a vaginal examination was made, and it was found that the uterus was the site of a large growth, probably carcinomatous, which involved the cervix, but the mass was not very fixed, and there was not much ulceration. Mr. Carless discussed the influence of this observation on the question of operation, and stated that obviously the disease had progressed to such an extent that a cure was impossible, and, indeed, it was doubtful whether it was wise to do anything; on the other hand, the limb was exceedingly painful to every movement, it had to be kept in a sling, and even then was a great nuisance to the patient; it seemed, therefore, likely that removal of the arm and growth would conduce to the patient's comfort. As to the extent and character of the operation, he pointed out that the encroachment of the growth on the upper end of the bone was so great that amputation through the shoulder-joint would probably not take away the whole of the mass, therefore he proposed to remove the complete upper extremity. An incision was made along the clavicle, and the central portion of the bone was removed, leaving about three-quarters of an inch at the inner end; the subclavian vessels were ligatured in two places and divided between the ligatures; the supra-scapular artery was picked up and ligatured before dealing with the main vessels. An incision was then carried from the centre of this wound downwards and outwards across the anterior fold of the axilla and the axilla itself

as far as the lower angle of the scapula, the skin and subcutaneous tissues were dissected up for an inch or two, then the pectorales, major and minor, were divided as also the subclavius, costo-coracoid membrane, and the brachial nerves, the latter being drawn down and severed as high as possible; the axillary space was opened up, but the serratus magnus was left in contact with the chest wall. The arm was now drawn well over the chest towards the opposite side, and the final incision was made, reaching from the outer end of the first cut to the inferior angle of the scapula, joining there with the former incision; the skin and subcutaneous tissues were dissected up from over the scapula till its vertebral border was reached, when the muscles connecting it with the spine were severed, as also the levator anguli scapulae, under cover of which the posterior scapular artery was found. A few touches of the knife cleared the lower angle of the bone and divided the insertion of the serratus magnus, thereby freeing the limb. A few bleeding points were picked up on the chest wall and ligatures were applied. The wound was next brought together and the flaps were found to fit satisfactorily. A drainage-tube was inserted at the lower angle, and the linear wound was then closed. Mr. Carless remarked that in this procedure he had followed Berger's method, which gave the most satisfactory results. He pointed out that the shock from this operation was very slight, owing to the very slight loss of blood that the patient sustained. Examination of the limb demonstrated the wisdom of the high operation having been undertaken, as it would have been scarcely possible to have got between the growth and the coracoid process; the shoulder-joint itself was free.

It is satisfactory to note that eight days after operation the patient was going on well. The shock had been slight, there had been no traumatic fever; the tube was removed in forty-eight hours, and the wound had not again been dressed.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 6d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books &c.—Seven lines or under (70 words), 4s. 6d. per insertion 6d. per line beyond.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JANUARY 14, 1903.

AN OBJECT-LESSON IN DEATH CERTIFICATION.

It is generally recognised that a reform of the present system of death certification must form one item in the legislation of the near future, and

an excellent object-lesson is furnished by the evidence at some recent police-court proceedings at Wigan. It appears that the mother of the deceased child informed the doctor of the death of the infant on one occasion, only to find on her return that the child was still alive, although she was the possessor of a certificate to the effect that death had taken place. The next day she made a fresh application and obtained another certificate, but the recalcitrant infant did not actually expire until four or five days later. Well might the magistrate comment contemptuously on the giving of certificates on hearsay; a more flagrant example it would indeed be difficult to allege. It is, however, only fair to say that no particular blame attaches to the medical man, who appears in an invidious light as having given these various certificates. He only conformed to the usual practice, which is to certify death on the affirmation of the parents or guardians. This “comedy of errors” shows how utterly untrustworthy is the present system of death certification, and proves—if further proof were necessary—that no system which dispenses with personal inspection of the corpse can possibly be satisfactory. We place this flagrant instance at the disposal of the Committee of the General Medical Council which is entrusted with the task of calling the attention of the Privy Council to the shortcomings of the system in vogue. As we are in ignorance of the precise nature of the modifications to be suggested by the Council we would premise that, to be efficient, any system of death certification must provide for personal inspection of the deceased person; that the certificate should be handed direct to the registrar, the practitioner issuing the certificate to him instead of to the parents or guardians, and that in respect of every death not certified by a duly registered medical practitioner the matter should be referred to the Coroner for the district in view of an inquest should this official, in the exercise of his discretion, deem an inquiry to be necessary. These are the main points, but any scheme of reform would doubtless comprise sundry other points of social, rather than of medical, interest. For instance, the question of the identity of the deceased ought to be established in a more certain way than is at present provided for. Under existing regulations it is open to the declarants to register the deceased under such names and descriptions as they may deem fit, and the registrar is not authorised to exact any documentary evidence of the authenticity of the alleged facts. There are plenty of instances to show with what ease and certainty utterly misleading declarations can be, and have been, made, and the penalties provided for such misdemeanours are ridiculously inadequate. An offence of this kind is not one to be met by a mere fine. It constitutes what the French call a *faux en écritures publiques*, an offence which is visited with condign punishment, as it deserves to be. Even the identity of the declarants is a detail worthy of more attention than it has so far received. The law requires that the person making the declara-

tion shall conform to certain degrees of parentage or responsibility, but the moment no evidence is demanded of the truth of the declaration the provision becomes inoperative. Of course, in the ordinary course of events such rigour may not be required, but the law must make provision for cases in which the declarants are interested in deviating from the truth, and under existing circumstances we have no means of knowing to what extent the laxity of the law is abused. It will be seen that the subject is one worthy of the earnest attention of our legislators, and medical practitioners are perhaps more interested than any other class of society in obtaining guarantees of the accuracy of the procedure in matters of death certification. There is one more point which must not be lost sight of, *viz.*, that if medical men, who are the corner-stone of any system of death registration, are required to assume the responsibility of distinguishing between deaths due to natural causes and those calling for further investigation, it is only proper that provision should be made for their remuneration.

THE LONDON UNIVERSITY PARLIAMEN- TARY DEADLOCK.

THE scientific claims of Sir Michael Foster to a high place in the esteem of his fellows are, of course, universally acknowledged. As to political status, however, it seems not unlikely that recent events will considerably lower the confidence of the electors of the London University in the consistency and resoluteness of his purpose. As everyone knows, at a critical period in the passage of the Education Bill lately passed by Mr. Balfour's Government, Sir Michael Foster, then sitting on the Unionist benches, publicly announced that he could no longer support the measure in question. The letter conveying that information was published on November 28th of last year, and stated specifically that the education policy of the Government was in certain features "out of harmony with the spirit of the University of London, and contrary to the views of the majority of my constituents." Immediately after the publication of that letter the candidatures of Sir J. Williams and of Sir P. Magnus, both of them Liberal Unionists, were announced; and a few weeks later Sir J. W. Collins entered the lists as a Liberal candidate for the vacancy it was assumed would shortly follow. Sir J. W. Collins now states that on December 14th Sir Michael wrote to the effect that he did not intend applying for the Chiltern Hundreds that week, but should at once do so should either of the candidates feel aggrieved. On December 19th, Sir Michael informed Sir J. W. Collins that the latter might expect to hear at any moment that the reasons for resignation no longer existed. On January 2nd, 1903, Sir Michael Foster wrote to Sir J. Rotton saying that unless the University wished him to resign he should continue its member. From further statements it seems that he proposes to change to the Liberal side of the House, but does not bind himself as an academic representa-

tive to support either party. This attitude will probably be regarded as altogether too "academic" for the field of practical politics, however necessary or desirable suspended judgments may be in the conduct of scientific investigation. The constituents of the University of London, if we mistake not, will want a man with his mind made up to represent their views as a body in Parliament. Strength of conviction, tenacity of purpose, a wide grasp and an intimate knowledge of the circumstances of the times are needed in the representative of a great University. Mere shilly-shally academic wavering among Members of Parliament when vital national issues are at stake would speedily shake the boasted greatness of the British Constitution to its foundations. After all that has been said and done during the last few months it seems impossible that Sir Michael Foster can seriously propose at this late hour finally to withhold his resignation. In any case we fail to gather how a vote of confidence can be registered in his favour by any other means than that of a contested election. The appearance of three powerful candidates on the mere prospect of a vacancy in itself proves conclusively the existence of strong and widely differing political views among the constituency of the University of London. Neither candidates nor constituents are likely to accept Sir Michael's determination to retain his seat with anything like complacency. The candidates have good ground for complaint, inasmuch as Sir Michael has intimated again on several occasions definitely enough, his intention of retiring. It seems now that a public pledge of that kind must be absolutely binding upon a man of Sir Michael Foster's high character and standing, no matter what private and political pressure may have been brought to bear upon him. The constituents, on the other hand, have reason to complain that their representative did not speak out boldly, either on one side or the other when the Education Bill, in which they were closely concerned, was before Parliament. Moreover, since the date of Sir Michael's election, the number of constituents has been enormously increased, so that the choice of a few years ago may be no longer the choice of to-day, especially in the light of recent events, and the intervention of political issues of so contentious a character that they profoundly disturbed the Parliamentary conscience of Sir Michael Foster himself. The contention of the latter that circumstances have altered to such an extent as to warrant him in retracting his resignation applies with equal, or rather with far greater, force to the position of his opponents. The new electorate may reasonably claim a member who will represent their views. For that purpose they will probably prefer one who is able to speak out with dignity and authority upon scientific and educational matters. At the same time it seems impossible to avoid the discharge of party responsibilities attending such representation. It would be wiser, in our opinion, to elect a man of definite political opinions who would sit and vote on one side or

other of the House, and who would preferably be a man of scientific attainments. With the profoundest respect and admiration for Sir Michael Foster, it seems to us that he can hardly withdraw his resignation without violating the high ideals that although held in small regard in political life, we are nevertheless accustomed to consider as simple matters of faith and conscience in a man of Sir Michael's position.

Notes on Current Topics.

Electro-Therapeutics and Quackery.

Mr. EDMUND OWEN'S address delivered at the first annual meeting of the British Electro-Therapeutical Society is deserving of the serious attention of the medical profession generally. Mr. Owen considers that hitherto the subject of the treatment of disease by electricity has received but scant professional recognition, and that, in consequence, the practice of medical electricity has largely fallen into the hands of quacks. This is becoming a more serious matter every day. In the past, patients were placed on insulated stools and made to emit sparks, or their hair was caused to stand on end, or they received shocks of varying degrees of severity; they paid the price demanded, and that was all. Nowadays, however, the resources of electricity are more widely exploited, and the resultant harm to the public is greater. The Finsen light is used for all kinds of diseases, the X-rays show the gullible patient some extraordinary condition which it will require a further course of electricity to cure, and so on. "What should you do," said a medical man to an attendant at an electrical establishment in the west of London, "if a new patient came in requiring treatment by the Finsen light and the manager was absent?" The answer was, "I know lupus, and I should treat it"! The neglect of electro-therapeutics by the medical profession is shadowed in the poor repute in which *bonâ-fide* medical men who practise in the field of electro-therapeutics are held by the public. It is time that this condition of affairs be changed, both in the interests of the public and the medical profession, and if the British Electro-Therapeutical Society can bring about the change it will have accomplished a valuable task.

The Late Professor Krafft-Ebing.

THE recently-recorded death of Baron von Krafft-Ebing, formerly Professor of Psychiatry in the University of Vienna, will recall to the minds of medical men the curious work of which he was the compiler, and which brought his name into a somewhat unfortunate prominence. That the author of "Psychopathia Sexualis" published that work with a definite scientific purpose, and under the impression that it would be of value to members of the medical and legal professions, is doubtless true; but we fancy that most of those who have read, or even glanced at it, will agree that however good the motive, the work itself was

the result of a gross error of judgment. The excuse offered for the production of such works, that they deal with actual facts of life which it is important to know, is absurd. Facts are not of value merely because they are facts any more than the collection of rubbish in the pocket of an imbecile is of value because it is matter of some sort. Krafft-Ebing related an enormous number of what were admittedly facts, but still their value was nothing, because no practical deductions were to be drawn from them save that human bestiality assumed many different aspects. If certain knowledge is detrimental to the morals of a great number of people there must be some convincing reason for publishing it in a form which enables such people to obtain ready access to it. Krafft-Ebing must suffer in reputation not on account of the motive which led him to write the book in question, but because he was unable to appreciate the relative value of facts.

Immediate or Late Operation in Appendicitis?

PROMPT operative interference in cases of acute appendicitis has become so much the rule with surgeons that we feel almost as if an apology were necessary for bringing under notice the good results that some French surgeons have obtained by deferring the operation until the acute symptoms have abated. Though there are some cases that rapidly pass from bad to worse and terminate in gangrene, there are other cases in which ice poultice and opium often produce a marked remission of the fever, a diminution of pain, and sleep. M. Michaux, addressing the Surgeons' Society of Paris, stated that such treatment favours the benign action of the leucocytes, localises the inflammation, and promotes the absorption of the effused products of the inflammation. Statistics so far go to confirm Michaux's views. Of eighty-four patients operated upon during the pyrexial stage he lost eight, and of fifty operated on when the temperature fell to normal he lost but three, one of whom was an albuminous patient sixty-five years old, and the other two were infants who were so lowered in physical health by auto-intoxication as to be beyond hope from the first. M. Potherat's statistics are even more favourable. Since 1901 he has operated for appendicitis 115 times; in seventy nine cases he performed the post-pyrexial operation without losing a patient, and in thirty-six cases he operated during the height of the fever, with twenty-five successes and eleven deaths. Statistics do not, however, in this question help us much. Mild cases are more amenable to medicinal aid than severe cases, and in mild cases the patient has not as large a dose of the toxin and is in a much better condition for operation. In severe cases there is great prostration, both from the toxin, loss of sleep and pain; such cases are not amenable to medicinal treatment, the inflammation has no tendency to become localised. Among such the death-rate must ever be high.

A New View of Typhoid Fever.

THE exclusive water-borne theory of typhoid infection must be abandoned in that it has been shown to be inadequate to explain the incidence of the disease in many instances, notably in regard to the prevalence of the disease among the troops in India. Not, indeed, that it can be denied that the majority of well-marked epidemics are attributable to this cause, but it is not, as has been generally believed, the only possible, nor even the principal, cause of the seasonal spread of the disease. Quite recently, it has been demonstrated that the *materies morbi* is not confined to the fæces, but is contained in the urine and other dejecta. Professor Koch goes a step further and asserts that the malady is directly transferable from one person to another, hence the importance of early diagnosis and strict isolation of the infected. It is quite possible that the exclusive attention hitherto devoted to the conveyance of the disease by contaminated water has blinded us to other less frequent, but nevertheless very potent, sources of infection. Milk has been recognised as one vehicle of infection, but by the agency of flies and similar parasites many other modes of infection are suggested. Water-borne infection is absolutely preventible and ought to be prevented, at any rate in our large towns. The diminution in the typhoid death-rate on which we are congratulating ourselves represents, after all, but a small proportion of the mortality from this essentially filth-disease, and the inadequacy of the methods of prevention actually practised is of itself evidence that we have not yet succeeded in obtaining a firm grasp of the subject.

The Size of Women's Brains.

ONE of the newspaper things that is always with us, verdant and flourishing as the green bay tree, is the size of women's brains. An indignant lady has recently written to the *Westminster Gazette* challenging the statement that "the mean weight of the brain in women is *without exception* smaller than that of equal height." The correspondent's remarks hinge on the italicised words "without exception," but we fail to see that they have any logical meaning in a general statement as to an average measurement. The fair lady, therefore, is simply beating the air when she cites her height and the size of her own head and challenges comparison with males of same height. Clearly there must be exceptional sizes of brain both in women and in men. For all that, the general proposition may be accepted that the average female brain is some five ounces less in weight than that of man. It is no less true that the average number of red blood corpuscles is some 500 less per cubic millimetre in women than in men. We hope, however, that no perfervid champions of either sex will argue from that fact that Nature has unduly handicapped the gentle sex. The correspondent above alluded to is on surer ground when she says that the skulls in most of our museums are those of the poorer classes, so that educated brains are not fairly represented. This observation is credited to Sir William

Flower. In any case the suggested fallacy offers a good field of investigation, although we dare not hope that the vexed question will ever finally be settled.

Medical Registration Reform.

THE notoriously parlous condition of the finances of the General Medical Council has long been known to the outside world. Indeed, so serious has grown the discrepancy between income and expenditure that the Council has drafted a Medical Acts Amendment Bill, the main object of which is to readjust the financial system of the Council on a sounder basis. In their legislative scheme it is proposed to add to income from two sources, namely, from medical students and from medical practitioners. It is proposed to form a compulsory register of students, who will pay an entrance fee of £1. As regards qualified practitioners the simple expedient is to double the present registration fee of £5. The anomaly of these proposals is somewhat startling. For instance, how in the name of consistency could any self-respecting body propose that registration should be compulsory for students but voluntary for qualified men? If the ordinary registration fee is to be doubled, why should it not in a few years time be trebled or quadrupled? The General Medical Council, in our opinion, would have done much better to treat finances as part of a suggested new Medical Act, framed so as to meet many of the standing grievances of the profession, and not merely to bolster up the finances of the Council. The question of registration, moreover, requires firm and broad handling. It should, in the opinion of many competent critics, be rendered compulsory and maintained, as in the case of the legal profession, by an annual payment.

Coroners and Post-Mortem Pathologists.

THE meeting of the South-West London Medical Society, which took place a few days since to discuss the recent action of Mr. Troutbeck, the Coroner for Westminster, in respect of the making of post-mortem examinations by a special official, was well attended and afforded unmistakable evidence of the feeling which Mr. Troutbeck's action has excited. Counsel's opinion was read to the effect that the Coroner has no legal authority to cause the post mortem examination to be made by other than the medical man who had been in attendance on the deceased, according to the clauses of the Coroners' Act, 1887. There does not appear, however, to be any ready means of calling to order a Coroner who violates the spirit as well as the letter of the Act. The discussion made it plain that no objection is anywhere felt to the employment of a skilled pathologist in special cases, and it goes without saying that his assistance would gladly be received under special circumstances. The gravamen of the protest applies to the supersession of the ordinary medical practitioner, a course adopted by Mr. Troutbeck in violation of the statute to which reference has been made. After considerable dis-

cussion, a resolution was passed directing that the attention of the London County Council should be called to the practice of confiding all post-mortem examinations to a specially selected pathologist, in direct opposition to the resolution of the Council, which was to the effect that this course was only to be adopted in cases of a special nature. The resolution concluded with an assurance that they would welcome the assistance of a skilled pathologist in suitable cases, but protesting against the interpretation that had been placed upon the Council's resolution. The matter will thus certainly receive the serious attention of the Council, and we may hope that specific directions will be given to coroners in this connection.

"The Medical Press and Circular."

IN the first number of the present volume advantage has been taken of recent improvements in the art of printing to ensure a high standard of production hitherto unattainable. The wear and tear of the characters resulting in blurred and imperfect impressions have been effectually obviated by recourse to a system of casting new type for each weekly issue, with results which our readers cannot have failed to appreciate. We feel that the introduction of this innovation will prove acceptable to our readers and will go far to keep the standard of the mechanical department on a level with that at which we aim for the literary department.

The First Egyptian Medical Congress.

THE first Egyptian Medical Congress, which came to an end on Christmas Eve, appears to have been a great success, both from a social point of view and the more important standpoint of the actual work accomplished. The Congress commenced on December 19th, when the opening ceremony was performed by the Khedive in the Opera House. The Khedive, speaking in French, expressed his gratification at the advances of Egyptian medical progress and his pleasure at seeing the representatives of so many countries present. A long series of addresses delivered by the various delegates followed, Mr. Reginald Harrison, F.R.C.S., speaking as the delegate of the Royal College of Surgeons of England and the representative of Great Britain and Ireland. At the conclusion of the ceremony, Professor Bouchard delivered an address on "Modern Tendencies in Medicine." It seems curious to have included an address on a purely medical subject at an opening meeting at which so many non-medical men were present. In the afternoon the Khedive held a reception. The work of the three sections—Medicine, Surgery, and Ophthalmology—commenced on the 20th, and lasted until the 23rd. On the evening of the 20th, the annual dinner of the School of Medicine was held, and proved a great success. The final general meeting was held on the morning of the 24th, when the delegates took their formal leave, and several general resolutions, the most important of which related to sanitary matters, were adopted. It was an-

nounced that the next meeting of the Congress would be held at the end of December, 1907.

The Treatment of Gastro-Intestinal Hæmorrhage of the New-Born.

THE treatment of the rare condition known as gastro-intestinal hæmorrhage of the new-born, or *melæna neonatorum*, has, in almost every case, proved unsuccessful, and, consequently, any advance in it is of considerable interest. In the current number of *American Gynecology* Dr. J. F. Moran records a case in which the sub-cutaneous injection of salt solution and gelatine was followed by a most successful result. An infant, weighing about 6½ pounds, commenced to vomit small clots of blood twelve hours after birth. Twenty-four hours later it became very much collapsed, and, on removing the diaper, the latter was found to be saturated by from six to eight ounces of a tarry fluid. The usual methods of attempting to check the hæmorrhage were tried without benefit, and then Dr. Moran determined to inject salt solution and gelatine hypodermically. About four ounces of the solution were used, and were injected in equal quantities under each breast. The result was quickly seen and was most satisfactory, the pulse increased in strength and frequency, and the respiration became more normal. The succeeding stools still contained varying quantities of blood for twenty-four hours, but then all trace of it disappeared. The cause of hæmorrhage in these cases is obscure. In a case described by Zezschwitz many years ago a duodenal ulcer was found close to the pylorus. Syphilis is probably an important pre-disposing cause, as may be also congenital malformations occurring in the vascular system. If the hæmorrhage occurs in the form of oozing from an ulcerated surface, the increased tendency to coagulation of the blood, to which the injection of gelatine may give rise, may be sufficient to cause the deposit of a layer of fibrin over the ulcerated surface sufficiently firm to check the hæmorrhage.

The Forthcoming Parliamentary Election in Dublin University.

So far as can be at present seen, there will be two candidates for the vacancy in the representation of Dublin University in Parliament—Mr. Campbell (the Solicitor-General), and Mr. Arthur Samuels. The number of medical men who are electors is considerable, and, if it were necessary on a question of the interests of the medical profession to endeavour to secure the election of a particular candidate, it would be easy for them to do so in the present almost equally divided condition of the constituency. So far as we can see, however, both candidates are equally well disposed towards the medical profession in general, and especially towards that burning question in Irish medical politics, the interests of the Irish Poor-law Medical Service. Mr. Campbell, when formerly M.P. for the St. Stephen's Green Division, actively interested himself in that service, and as can be seen from a letter of Mr. Samuels, which

was published in our last issue, that gentleman has expressed very decided views on the necessity for reform, and gave definite promise of his support. Accordingly, there is no necessity for the medical electors to determine to jointly support one or the other candidate, and their votes may be cast on wider issues. It is, perhaps, a matter of regret to many that a more purely academical candidate cannot be found than either of the gentlemen who are at present before the electors. We have every sympathy with a successful lawyer who desires to advance his interests by obtaining a seat in Parliament, and we are sure that, if elected, he will at the same time jealously watch the interests of his Alma Mater, but the reason for university representation is that an academic representative, as distinct from a party representative, should be returned. Accordingly, we greatly regret that a candidate of the type of Professor Lecky, who has just resigned, cannot be found.

The Curative Effects of the Open-Air Treatment of Phthisis.

ALTHOUGH the open-air treatment of pulmonary tuberculosis has "taken on" with unwonted success so far as public support goes, we are still in want of really trustworthy statistics of the results obtained thereby. It can hardly be questioned that the immediate result is eminently satisfactory in that the patient almost invariably gains in weight and recovers energy and strength, but, from a practical point of view, what we require are accurate data of the subsequent history of the patients thus treated. It is in this way only that the value of the term "cured" or "improved" can be estimated. It may safely be premised that a patient who has recovered under this treatment re-enters civic life under less favourable circumstances than he entered it, since his lungs, even assuming that all tuberculous lesions have healed, and (though this must be the exception) that all foci of inspection have been eliminated, remain more amenable to tuberculous influences than those of a normal, healthy individual who has not gone through the fire. This being the case no argument is needed to prove that if such an individual return to his previous occupation and resume life under the same hygienic conditions as before, re-infection must only be a matter of time. Further, in the majority of patients, return to re-existing conditions is the best that can be hoped for, while in a not inconsiderable proportion the difficulty of gaining a livelihood may be enhanced by the enforced absence. If then the result of the treatment be no more than to obtain a more or less ephemeral prolongation of life it is open to question whether it is worth the trouble and expense which it involves, and the money thus expended had not better be devoted to the improvement of the hygienic conditions of the working classes in order to prevent infection. The treatment of tuberculosis is sure to appeal to the public and to the profession much more convincingly than its mere prophylaxis, yet if ever the disease

is to be stamped out it will certainly be by preventive rather than by curative measures. It is well that we should look at the question from this broader point of view if only to mitigate the disappointment likely to be experienced when we come to analyse the results of this, as of every other method of treatment.

Medical Men of Colour in the States.

THE coloured medical man occupies an anomalous, and in many respects, unenviable position as a citizen of the United States of America. Men of his own colour are apt to pin their faith to white men in medical matters, while white patients would clearly be unlikely to employ the services of coloured practitioners. The coloured medical man, moreover, shares the intolerant social ostracism which the modern American sees fit to fix upon the African race in that country. Quite recently, President Roosevelt, that most energetic reformer, has made an official appointment, whereby he apparently wishes to protest against the racial disabilities attached to coloured citizens. It is reported, on what appears to be good authority, that he has appointed a negro physician, Dr. Crum, to the post of Collector in the port of Charleston, in South Carolina. The post is, of course, political, and probably illustrates the difficulty of conferring upon a coloured practitioner any official position connected with his own profession. The native medical man from other parts of the world often proves a most capable and highly qualified medical practitioner. It is to be hoped that President Roosevelt will succeed in vindicating the claims of the coloured medical man in the States to reasonable social recognition. In some islands in the West Indies the professional African has more chance of finding a field for his activities.

Congenital Hip Disease.

As if to support Dr. Lorenz's theory that "the operation for congenital dislocation of the hip might be successful after eight and a half years, but would require very gradual treatment," he met with his first failure in Boston. For exactly twenty-one minutes, before a crowded theatre, Dr. Lorenz, aided by his colleague, Dr. Fritz Mueller and two strong young surgeons, pulled, kneaded, tugged, rotated the leg of a boy of ten unsuccessfully, although the dislocation was considerably reduced. His second operation that day was on a girl of four with bilateral dislocation. But the double operation was performed in the record time of four minutes. "Bloody surgery," says Dr. Lorenz, "tries to correct the deformed members by extirpating parts of bones not in their proper places. Bloodless surgery restores the bones to their proper places. If the former method united swiftness and sureness it might be called the superior. Plastic bloodless surgery regards human tissue as plastic clay to remodel, its direct function being to stretch shrunken limbs until they take their natural position."

Bacteriology and Public Health.

THE great and increasing importance of bacteriology in public health has been recognised for many years past. Indeed, it may be said that the control of a medical officer of health over infectious diseases in his district to a large extent depends upon the amplitude of the means at his command of obtaining rapid and trustworthy bacteriological information. That fact has been recognised by many sanitary authorities, as shown by the organisation of a system whereby free bacteriological tests have been placed at the disposal of local medical men in suspected cases of diphtheria and of enteric fever. In a not distant future, however, it is likely that in the field of routine public health bacteriology will be greatly extended. It is an essential feature of a bacteriological service of the kind that it should be carried out at the public cost. Moreover, under the circumstances of the case, it is impossible that any medical officer of health, however able and energetic, can find time himself to undertake the necessary laboratory work. In Bristol the service established by Dr. Davies in 1895 has yielded important results in the tracing of the origin of the famous milk typhoid of 1897, and in helping to suppress diphtheria. The cost has averaged about £170 a year, but the Health Committee has now wisely resolved to transfer the work bodily to University College, Bristol, where it will be carried out under the superintendence of Professor Kent. In this way Dr. Davies will be relieved of a large amount of technical work, which will enable him to devote his energies to the labours that have done much to place the ancient city of Bristol in the forefront of municipal sanitary administration.

Sex Productions.

THE physiology of sex production will probably continue to occupy the minds of observers in spite of the disgrace which the late Professor Schenk brought upon himself by the untimely publication of an inadequately studied and improbable theory of the artificial production of sex. Kolipinski has studied sex production, taking 192 families and dividing them according to types as to the first three births. The theory which he advocates is that the person of the greatest will-power will produce his own sex first; understanding by will-power, decision, determination and resolution. He states that more males than females are born and that twins are more common among boys than girls, that older fathers produce more boys, and that wives older than their husbands produce more girls, and he explains the latter fact on his theory that the older person has the stronger will. Prostitutes give birth mostly to boys, which he also explains on the ground of their debilitated will-power. Jews have more boy children than their surrounding races. Finally, male drunkards produce boys, but whether this is due to the chronic alcoholic poisoning of the fathers or results from the abject and miserable state of the mothers, is an open question.

The Abolition of the Coroner's Office.

ALTHOUGH it has long been felt that coroners' inquests leave much to be desired in respect of practical utility, being in fact a relic of bye-gone times, public feeling in this country has not gone so far as to demand their suppression. In the State of New York, where ideas move more rapidly, a movement is actually on foot to abolish the office of coroner, and the proposal receives the cordial support of our contemporary the *Journal of the American Medical Association*. It is pointed out that the judicial functions exercised by the coroner would be better exercised by other state officials, while the medical element would in any event be adequately represented by the medical witnesses. The office of coroner was abolished in Massachusetts some time since, apparently with advantage, and New York seems anxious to follow the example. It will probably be some years yet before the popular conception of the coronership in this country endorses the description given by our contemporary as "an expensive relic of monarchical barbarism."

Enlarged Thymus Gland.

THE thymus gland is one of those out-of-the-way organs which are very apt to escape attention. It is not credited with any adult function and, at any rate until very recently, was not known to give rise to any pathological disturbances. It is, however, useful to remember that it may, and occasionally does, determine very serious symptoms and in some instances has been the cause of sudden death. Grawitz was one of the first to call attention to the medico-legal importance of enlarged thymus as a factor in the production of sudden death, and he has recently published two further cases in support of his contention. When the gland is the seat of marked enlargement it may press upon the trachea, causing obstruction which escapes observation until some fortuitous circumstance exaggerates its effects and brings about asphyxia. In one instance partial was converted into complete obstruction by the throwing back of the head in the act of swimming; and apart from the direct pressure which it exerts upon the trachea, an enlarged thymus may impede the circulation in the two large veins and so determine loss of consciousness.

PERSONAL.

M. ADOLF DEUCHER, who has just been elected President of the Swiss Republic for the third time, is a member of the medical profession.

DR. AUSTIN MELDON, F.R.C.S.I., has resigned his position of Surgeon to Jervis Street Hospital, after being attached to the Institution for thirty-five years.

DR. MALINS has resigned the post of Honorary Obstetric Physician to the Birmingham General Infirmary, having accomplished twenty-five years' service.

HIS GRACE THE DUKE OF NORTHUMBERLAND, K.G., has become President of the Imperial Vaccination League in succession to his Grace the Duke of Fife, K.T.

THE Right Hon. Lord Strathcona has consented to preside at a Festival Dinner in aid of the funds of University College Hospital on Wednesday, March 18th next, at the Hotel Metropole, S.W.

DR. EDMUND BRANCH, Medical Officer of Dominica, West Indies, has been transferred to St. Kitts as a District Medical Officer, and is succeeded by Dr. Dudley Greaves, of Nevis.

DR. FRED DITTMAR, M.A., M.D., of Glasgow, has been appointed Medical Officer of Health for the borough of Scarborough, in succession to Dr. Heywood, Waddington, formerly of Oldham, resigned.

DR. HEYWOOD SMITH has been elected president, Dr. Wm. Travers, treasurer, and Drs. Swanton and Jervois Aarons, hon. secretaries of the British Gynaecological Society for the ensuing year. Dr. J. J. Macan has been re-elected Editor of the Journal of that Society.

DR. T. S. KERR, Principal Civil Medical Officer of the Straits Settlements, is stated to have resigned that appointment. He is at present on leave, having come to England some time since to undergo an operation. Dr. Kerr entered the Straits Civil Service in 1883 as Colonial Surgeon of Penang, and was promoted to his present office in the year 1900.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents].

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

UNIVERSITY OF EDINBURGH.—From the annual report for 1902, just issued, it appears that the total number of students was 2,918, including 301 women. Of these, 1,396 (including 15 women) were in the medical faculty, and 195 (including 1 woman) in that of science. Of students of medicine 648 were Scottish, 327 from England and Wales, 112 from Ireland, 74 from India, 211 from British Colonies, and 24 from foreign countries. The number of women attending extra-academical classes with a view to graduating in medicine in the University, was 102. The degrees of M.B.C.M. were conferred on 6 men and 1 woman; of M.B.Ch.B. on 165 men and 15 women, of M.D. on 67 men and 1 woman. The certificate in tropical medicine was granted to 22 men and 1 woman. The first instance of a woman having received permission to deliver a course of intramural lectures occurred this year, when Miss Robson, M.A., gave five lectures on German pronunciation. The Carnegie bequest, which has now been in operation for over a year, doubtless accounts for a marked increase in the fee fund by enabling students to take out a larger number of classes than they would otherwise have done. The annual grant of £11,500 under the second head of the gift is apportioned thus:—Building and permanent equipment, £8,000; teaching, £2,500; library, £1,000. As the allocation by the Carnegie Trustees is inadequate, an appeal will shortly be made to the public for subscriptions "for the further development and extension of the university." A movement for the extension of the University Union is to be inaugurated at an early date, and a movement has been started to provide a habitation for the Indian Association. Among the numerous benefactions received during the year mention may be made of Sir A. Conan Doyle's gift of £1,000 for the foundation of a prize to be awarded annually to the most distinguished South African graduate in medicine of the year. This prize was provided from the proceeds

of Sir Conan Doyle's book on the war. Intimation has also been received of a bequest by the late Robert Rowe, F.C.S., for the ultimate foundation of a Professorship of Bacteriology. Numerous donations to the library are mentioned, including a collection of works on tropical medicine by Dr. Davidson and a portion of the scientific library of the late Professor Tait. The re-cataloguing of the library is now complete so far as the general library is concerned, except for some small special collections; 199,990 volumes have been dealt with in 168,460 entries and 19,300 cross references. The physiological and medical and other books in the reading-room of the new university buildings have also been dealt with. The printing of the students' hand catalogue has been delayed pending its entire revision by one of the librarians. The work of the Public Health Chair was transferred to the Usher Institute in October, the Institute itself having been handed over to the university in June last. Among changes in the office bearers the chief are the resignation of the Principal and the death of Lord Dufferin, the Lord Rector. Among innovations which the past year has witnessed the institution of a special course of instruction in the administration of anaesthetics has to be recorded. For the first time also, women have been admitted to the classes in the Faculty of Divinity; a special course of instruction in diseases of tropical climates has been held for women, and the certificate in that subject has been conferred on a woman candidate.

BELFAST.

[FROM OUR OWN CORRESPONDENT].

MEDICAL MEN ON THE CITY COUNCIL.—Elections take place this week in fifteen wards for a Councillor in each ward, and in four of the wards the retiring members who seek re-election are medical men—Drs. O'Neill, Williamson, F. White, and A. V. Browne. Two other medical men were nominated, but retired from the contest. Dr. O'Neill has been particularly active in matters relating to the health of the city, and has been instrumental in introducing a greatly improved method of meat inspection, and also a scheme for a municipal supply of sterilised milk. Dr. Williamson has been an active independent member of Council, bringing to light some of the hidden things of darkness that unfortunately abound in our municipal affairs, and hence is being strongly opposed when he stands for re-election. The two burning questions at the elections are the purchase of the tram system, which, as regards efficiency, has been steadily progressing backwards for some years, and the flooding of the city, with which the present authorities seem powerless to cope, and which has really become a very serious menace both to health and commerce.

ROYAL VICTORIA HOSPITAL.—A meeting of the committee was held on the 8th inst., at which it was reported that almost all the money promised for the new hospital was in hand, and the building rapidly approaching completion. It is hoped that the King may consent to open it if he pays his much hoped-for visit to Belfast in spring. It is said that the Right Hon. W. J. Pirrie, in a recent visit to America, procured "a number of new and special appliances for the use of the hospital." Happily for the profession he has not brought over any Yankee surgeons to teach us our business.

Society of Apothecaries of London.

PRIMARY Examination, Part II.—January 5th, 7th, and 8th, 1903. The following candidates passed in:—

Anatomy: G. E. Austin, H. D. H. W. Bund, H. S. Burnell-Jones, W. G. H. Cable, C. W. De Morgan, C. H. J. Fagan, F. C. M. Gabites, J. W. Rollings, E. Sutcliffe, R. M. Wingent.

Physiology: G. E. Austin, J. M. Burke, C. W. De Morgan, C. H. J. Fagan, G. W. Hassall, H. T. Roberts, E. F. Skinner, E. Sutcliffe.

Correspondence.

OYSTERS AND TYPHOID FEVER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Within the past few weeks there have occurred several deaths from typhoid in which the cause seemed almost beyond doubt traceable to the eating of oysters. Two particularly sad cases are those of a young bridegroom, a member of a well-known wealthy family, and his "best man," who both were affected in due course after partaking of a farewell bachelor supper at which oysters were the chief dish. The bridegroom developed the disease and died abroad during the honeymoon. The "best man" succumbed within a further few days.

The opinion which you express to-day is the one which I have always supposed was that held by the profession; namely, that typhoid bacilli will live in the tissues of the oyster after many weeks' exposure in pure fresh water; and that the only efficient method of prevention of oyster typhoid lies in the purification of the oyster beds from sewage matter. This being the scientific view of the case, it is a little astonishing to find Sir Henry Thomson in the *Times* of this morning stating that all that is needed to free oysters from dangerous organisms is to put them "into salt water to 'scour' for twenty-four hours." He adds that during this process "the intestines are completely emptied and any dangerous matter eliminated." The *Times* gives Sir Henry a prominent place and "double leaded" leader type. His dictum will be copied far and wide throughout the lay Press; and, if it be erroneous, the mischief to which it may give rise may prove truly terrible.

I am, Sir, yours truly;

January 7th, 1903.

H. S.

OBSTRUCTIVE DYSMENORRHEA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In self-defence, may I ask you to publish this, my last word, on the subject. I cannot agree with Dr. Herman's statement that Dr. Greenhalgh's stem possesses "all the properties of mine," and if those properties are meant to include even the death of one patient (one case again quoted), I deny that mine up to this have caused any. Dr. Greenhalgh's stem was designed for the treatment of flexions of the uterus, and was, so far as I know, never intended to be worn long enough to possibly effect a *lasting* cure in cases of obstructive dysmenorrhœa.

Therefore, if the solitary case of death quoted by Dr. Herman from the use of Greenhalgh's stem was a case of obstructive dysmenorrhœa, I am not at all surprised at the result. As it is more than probable the said patient died from septicæmia, caused by a fetid rubber stem with four small slits at top liable to be closed or blocked, and *very different indeed* from an *open metal flexible wire stem*, which will keep the cervical canal patulous and give free exit to the secretions.

I am, Sir, yours truly,

ALEXANDER DUKE.

London, W., January 10th, 1903.

CORONERS AND POST-MORTEMS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your article on "Coroners and Post-Mortems," you apparently assume that the appointment of Pathologist has been made officially by the London County Council, and that Dr. Freyberger has been so appointed. These statements are incorrect. I have a letter before me dated December 17th, 1902, addressed to me by the Clerk of the London County Council, from which I quote the following:—

"In reply to your letter of the 1st inst. I have to

inform you that Dr. Freyberger has not been appointed Pathologist to the London County Council, and it is incorrect to so describe him. On July 1st last the Council decided that coroners should be informed that, in the opinion of the Council, it was desirable that post-mortem examinations in inquest cases of a special nature should be entrusted to a specially skilled pathologist, and in accordance with the direction of a committee of the Council, the coroners were also informed that Dr. Freyberger was prepared to make such examinations and give evidence at the statutory fee of £2 2s., and that it might be desirable for them to avail themselves of Dr. Freyberger's services whenever the circumstances indicated that special pathological skill and knowledge were desirable."

I note that in the "Medical Directory" attached to Dr. Freyberger's name is a statement that he is "Pathologist to the London County Council," but as shown in Mr. Gomme's official reply, quoted above, the statement is "incorrect."

I am, Sir, yours truly,

A. GEORGE BATEMAN.

Medical Defence Union,

4, Trafalgar Square, W.C.,

January 7th, 1903.

Medical News.

The Gresham Lectures.

A COURSE of lectures on "Digestion" will be delivered on January 27th, 28th, 29th, and 30th, 1903, by E. Symes Thompson, M.D., F.R.C.P., Gresham Professor of Medicine, at Gresham College, Basinghall Street, London, E.C. Time will be given during the last lecture to answer questions bearing on the subject of the course. Questions to be sent in as early as possible. The lectures will be illustrated by diagrams, are free to the public, and commence each evening at six o'clock.

Death under Chloroform.

AN inquest was held at Kidderminster last week on a man who had died at the infirmary while undergoing an operation for the relief of cancer of the larynx. In spite of prompt tracheotomy and artificial respiration life could not be restored. Post-mortem, an extensive growth was found which amply explained the fatal result.

Non-Notification Case.

DR. C. B. LAWSON, of Charing Cross Hospital, was last week fined at the Woolwich Police Court for having failed to notify to the Medical Officer of Health for Woolwich that a patient seen by him at the hospital was suffering from typhoid fever. The defendant did not attend, but forwarded the penalty (£2), and a fine of £1 with £2 2s. costs was imposed.

Medical School of the Catholic University.

THE annual school dinner will be held on Thursday, the 22nd inst., in the Dolphin Hotel, Dublin, at 7 o'clock. Past students who desire to have places reserved for themselves or friends will kindly communicate with the Secretary of the Dinner Committee.

Dublin Death Rate.

THE deaths registered in the Dublin registration area for the week ending Saturday, January 3rd, 1903, represent an annual rate of mortality of 30.8 in every 1,000 of the population. Tuberculous diseases caused 17 deaths; diseases of the nervous system 15 deaths; diseases of the circulatory system 22 deaths; and diseases of the respiratory system 51 deaths. Of children, 58 died during the week, of whom 37 were infants under one year old. Within the City districts the death rate was 57.9 in the Castle Street district; 39.5 in the Black Ball Place district, and 38.8 in the Lisburn Street district.

The will of the late Mr. Lennox Browne has been proved at £14,873 2s. 6d.

Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, if resident in Ireland to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

RICHILL.—We fear that you cannot make the Guardians pay a "reasonable" remuneration, unless their own good sense prompts them to do so. They can refuse to pay your substitute altogether, and can equally refuse to pay him more than a certain rate. Mr. Wyndham has refused to make it at present compulsory on Guardians to grant an annual vacation, but he has stated that if he finds the Guardians habitually neglect to do so, he will consider the necessity of making it compulsory. This is not satisfactory, but it shows the importance of bringing every case in which vacation is refused to the notice of the Local Government Board, and refusal to pay reasonable remuneration is tantamount to refusal to pay any remuneration.

DR. H. W. S. asks us if we know of any medical diaries that are given away, exclusive of Burroughs and Wellcome's. We believe that beyond pocket almanacs and very small vest diaries none others are obtainable free except the one mentioned.

F. R. C. S.—The winner of the King's Prize of £500 for the essay on "The Sanatorium Treatment of Consumption" is a son of Professor Latham, of Cambridge, not the Dr. Latham referred to in your note.

CLIPPINGS FROM LAY EXCHANGES.

HOW IS THE PATIENT?

"Last Saturday, Dr. — performed an operation . . . which, from a scientific standpoint, places former recorded operations in the dark. — has been afflicted with plural effusion of the right lung. Dr. — inserted the pump, and after extracting about a pint was inclined to let it rest at that, but the patient was not in the least fatigued so he continued and removed the entire accumulation, 68 ounces, or more than half a gallon.

"Dr. — has the bottle and its contents on exhibition. The quantity removed is double what the authorities claimed to be a safe operation."—*Ione* (Cal.) *Echo*.

SLIPPED INNOMINATE.

"Mr. B. — had been examined and treated by a number of prominent physicians, but the cause of his trouble, which was usually diagnosed as sciatica, had been overlooked. His condition was one that osteopaths term 'slipped innominate,' the ilium on the affected side being slightly dislocated upward and backward."—*Ludington* (Mich.) *Record-Appeal*.

A DARNED RUPTURE.

"Dr. — and his assistants placed about twenty-five feet of silver wire in —'s abdomen in darning a rupture of the anterior abdominal wall."—*Chicago Chronicle*.

PHYSICIAN (at hospital): "I thought you merely had the measles?" Patient: "Well, isn't that enough?" Physician: "Yes; but you are covered with bruises from head to foot. How do you account for that?" Patient: "Oh, they brought me here in an ambulance."—*Chicago News*.

Meetings of the Societies, &c.

WEDNESDAY, JANUARY 14TH.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.)—8.30 p.m. Papers:—Dr. R. Andrews: Some Notes on Obstetric Practice in Berlin and Vienna. Dr. W. H. Kelson: On Nasal Discharges.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.)—5.15 p.m. Demonstration of Cases of Interest.

SOUTH-WEST LONDON MEDICAL SOCIETY (Bolingbroke Hospital, Wandsworth Common)—8.45 p.m. Paper: Mr. M. Yearsley: The Indications for the Mastoid Operation.

FRIDAY, JANUARY 16TH.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos Street, Cavendish Square, W.)—5.30 p.m. Specimens:—Mr. T. Walker: (1) Traumatic Cephalhydrocele; (2) Punctured Fracture of the Skull. Dr. C. W. Chapman: Dilatation of the Stomach in a Child of Eight Years. Paper:—Dr. G. A. Sutherland and Mr. T. Walker: A Case of Syphilitic Endarteritis and Nephritis in an Infant.

TUESDAY, JANUARY 20TH.

SOCIETY FOR THE STUDY OF INEBRIETY.—Quarterly General meeting at the London Temperance Hospital, Hampstead Road, 4 p.m. Paper by Dr. James Stewart on "Inebriety among Gentlefolk—A Twenty-five Years' Clinical Retrospect."

MONDAY, JANUARY 26TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN—8 p.m. Mr. Stanley Read, Mr. Morton Snaile, and Mr. J. B. Partitt will show cases. Mr. Arbutnot Lane, F.R.C.S., will read a paper on "Some Points in the Mechanics of the Jaws."

Appointments.

- BATHE, ALLAN ARTHUR, M.A., M.B. Oxon, District Medical Officer for the South District of Paddington Parish.
- BORLAND, HUGH HOWIE, M.B., C.M., D.P.H. Camb., Vaccinator to the Glasgow Royal Infirmary.
- CAMERON, S., M.B., Ch.B., Resident Medical Officer to the Chelsea Hospital for Women.
- FLUX, G. B., M.D. Brux., M.R.C.S., L.R.C.P. Lond., L.S.A., Assistant Anaesthetist to King's College Hospital.
- GREAVES, F. L. A., F.R.C.S. Eng., Honorary Surgeon to the Derbyshire Royal Infirmary.
- HEPPER, E. C., M.R.C.S., L.R.C.P., I.M.S., Clinical Assistant to the Chelsea Hospital for Women.
- HOLMES, W. S., M.B., Ch.B. Vict., Junior House Surgeon to the Oldham Infirmary.
- HOWE, JOHN, M.B., Ch.B. Vict., Medical Officer and Public Vaccinator to the District of Levenshulme and part of West Gorton (No. 8) of the Chorlton Union, Manchester.
- HUTCHEMS, H. J., D.S.O., Assistant Bacteriologist to the West Riding of Yorkshire County Council.
- MCCOY, S. H., M.B., B.A., Toronto, Clinical Assistant to the Chelsea Hospital for Women.
- McNAIR SCOTT, R. F., B.A., M.B., Ch.B., Clinical Assistant to the Chelsea Hospital for Women.
- MORRIS, J. M., M.A., M.B., C.M. Edin., Medical Officer of Health for the Borough of Neath.
- MURPHY, J. MONTAGUE, L.D.S.R.C.S. Eng., Honorary Dental Surgeon to the Derbyshire Royal Infirmary.
- MURRAY, G. S., M.B., Ch.B. Edin., Senior House Surgeon to the Oldham Infirmary.
- PERNET, GEORGE, M.R.C.S. Eng., L.R.C.P. Lond., Assistant to the Skin Department of University College Hospital.
- PORTER, CHARLES, M.D., B.Sc. Edin., M.R.C.P. Edin., Demonstrator in Bacteriology to the Public Health Hospital, Leith.
- SAVAGE, W. G., M.D. Lond., Medical Officer of Health for the Borough of Colchester.

Vacancies.

- Borough Hospital, Birkenhead.—Senior Resident Male House Surgeon. Salary £100 per annum, with board. Applications to Chairman, Weekly Board.
- Bradford Royal Infirmary.—House Surgeon. Salary £100 per annum, with board and residence. Applications to William Maw Secretary.
- County Asylum, Whittingham, Preston, Lancashire.—Assistant Medical Officer.—Salary £150, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.
- Liverpool Hospital for Consumption.—Stipendiary Medical Officer. Salary £70 per annum. Applications to Alfred Shawfield, Secretary, 77A, Lord Street, Liverpool.
- London Lock Hospital.—House Surgeon. Salary £80 per annum, with board, lodging, and washing. Applications to the Secretary, Harrow Road.
- Manchester Royal Infirmary.—Resident Medical Officer. Salary £150 per annum, with board and residence. Applications to W. L. Saunder, General Superintendent and Secretary.
- Royal Isle of Wight County Hospital, Ryde.—Resident House Surgeon. Salary £90.—Applications to Secretary.
- Saint Bartholomew's Hospital, Rochester.—Assistant House Surgeon. Salary £100 per annum, with board, washing, firing and light. Applications to the Clerk to the Trustees.
- Salisbury General Infirmary.—Assistant House Surgeon. Salary £75 per annum, with apartments, board, and lodging. Applications to the Secretary.
- Wrexham Infirmary.—Resident House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications immediately to J. Bagnall Bury, Secretary, 9, Temple Row, Wrexham.

Births.

- WAKEFIELD.—On Jan. 7th, at Lincoln Lodge, Horley, Surrey, the wife of Christopher Frank Wakefield, M.R.C.S., L.R.C.P., of a daughter.
- PORTER.—On Jan. 7th, at Helmsley, the wife of J. Francis Porter, M.D., J.P., of a daughter.

Marriages.

- GORDON—CRUDEN.—On Jan. 8th, at St. Mary Abbot's, Kensington, William Gordon, M.D., M.R.C.P., of 3, Barnfield Crescent, Exeter, to Dora Mary, elder daughter of Major Cruden, of Mellhouse, Shettleston, Lanarkshire, and Janefield, Nairn, N.B.
- PETTINGER—RISDON.—On Jan. 8th, at Old Cleeve Parish Church, James Wilson Pettinger, M.B., B.C. (Cantab.), of Kingsbridge, Devon, son of the late G. W. Pettinger, M.R.C.S., of Manchester, to Clare Sophie, daughter of John Risdon, of Golsuncott, Washford, Somerset.
- SHARPIN—HAXBY.—On Jan. 10th, at Christchurch, East Sheen, Henry Wilson Sharpin, F.R.C.S. Eng., of 34, Sillwood Road, Erith, to Jane, eldest daughter of S. H. Haxby, of Hatchliffe, Lincolnshire.

Deaths.

- EDDOWES.—On Jan. 8th, at Maddington House, Shrewton, Clara Elizabeth, the beloved wife of Charles Eddowes, M.R.C.S.
- PITT.—On Jan. 4th, at New Kleinfontein, P.O. Benoni, Transvaal, Tom Pitt, M.R.C.S. Eng., L.R.C.P. Lond., L.M. Rot. Hosp. Dublin, aged 34. (By cable.)
- O'CALLAGHAN.—On Jan. 12th, of 137, Harley Street, London, W., Robert T. A. O'Callaghan, F.R.C.S., Lieut.-Colonel 1st Flintshire Royal Engineers, in his 45th year.

SOME OF MY PRINCIPLES IN ORTHOPÆDIC SURGERY, (a)

By ADOLF LORENZ,

Professor of Orthopædic Surgery at the University of Vienna.

I CONSIDER it a great honour to be allowed to appear before you, and I know of no better way to show my gratitude than by asking your permission to explain to you some of my principles which hitherto have ruled my orthopædic work.

I hope to meet your approval at least regarding some of these principles. As to others which may rouse your opposition for the moment, I hope you will find them worthy of your objective trial. Even if these principles do prove to be different from yours, certainly we who are on both sides of that Atlantic which divides the place of our work, completely agree in the same aim, that is, to help our patients in the best way. As to my methods, I can recommend them as both safe and successful to the patient. In saying this I touch upon my leading principle, that is, curing my patients without danger of loss of life. Luckily, deformities seldom offer what we call, *indicatio vitalis*, therefore, when we operate on deformities we should never arouse even the possibility of putting the life of our patient in danger. Following this principle, I generally prefer bloodless operations to bloody ones. Usually the results are the same, but in many cases those of the bloodless ones are even better. As long as the bones are elastic enough, I prefer osteoclasis to osteotomy; this latter operation is exclusively reserved for adolescents and adults. In hip deformities I prefer bloodless corrections to osteotomy as long as even the slightest motility of the joint can be stated; only in cases of complete bony ankylosis do I operate with the chisel.

All cases of knee contracture I correct by the intra-articular modelling redressment, as long as even the slightest motility can be found. Only the cases of complete bony ankylosis of the knee-joint, which are rarer than is usually believed, are reserved for the bloody operation.

In all deformities of the foot, both paralytic and congenital, I rely exclusively upon my modelling redressment of the foot, and from a thousand-fold experience I can assure you that the results are generally beyond expectation. In my opinion, the wedge-shaped incision of the bones of the foot, newly recommended by the French, is nothing more than a deplorable mutilation of the foot. The results of the modelling redressment of club foot have been preferred by many others, and I am happy to say that at least in Germany, this method is predominant.

On the whole I daresay that I prefer bloodless operations to, bloody ones as long as any possibility exists of securing the result in this way. According to this principle I cannot sympathise with the total extirpation of the sterno-cleido mastoid in wryneck. In my experience the [subcutaneous

myotomy of this muscle in connection with the modelling redressment of the cervical scoliosis is perfectly sufficient to cure the *caput obstipum* thoroughly, and without leaving a scar. In this realm I go even further, as the congenital *caput obstipum* in children can be cured even without tenotomy, only by myorrhesis of the sterno-cleido mastoid muscle, and the results obtained by this method are the most perfect ones from a cosmetrical standpoint. The ruptured muscle regains its normal length as well as its normal elasticity to such a degree as to allow the head to move freely to the opposite side. Besides this, the ruptured muscle retains a normal prominence with its partner, restoring the normal configuration of the neck, in this way avoiding the known applanation of the operated side which usually occurs after open or subcutaneous myotomy.

Following this principle you will share many advantages with your patient. The latter readily consents to be operated upon as he runs no risk of life, and as for yourself, you will feel quite easy about him.

Another principle which I have always followed is the so-called central correction of deformities, which means that every deformity should be corrected in the vertex of its angle. If you should prefer to correct a deformity in one of the sides of the angle, even near the vertex, the deformity itself would remain, and instead of a correction you would have only a compensation for the deformity. This compensation implies some shortening of the side of the angle, that means of the leg, which shortening should be avoided under all circumstances. This principle is very important with regard to the contractures of the hip-joint. It is obvious that subtrochanteric osteotomy contradicts the above-mentioned principle. By correcting or compensating the deformity you shorten the leg. Agreeing with the principle of central correction, I always do central, that is pelvitrochanteric osteotomy. Having performed this operation, correction is very easy without causing any further shortening of the leg. I object even to oblique subtrochanteric osteotomy, although it avoids shortening by a complicated and difficult extension after-treatment, by which the patient is confined for some weeks to his bed instead of being able to get up a few days after the operation.

Following the principle of central correction you will also object to supracondylic osteotomy or osteoclasis in correcting the contractures of the knee-joint. In preferring central, that is, intra-articular correction, you will avoid shortening the limb. In correcting genu valgum the principle of central, that is to say, intra-articular correction cannot be thoroughly attended to because—except in cases of young children—a loose knee is to be feared, and besides the treatment takes too much time. In genu valgum supracondylic osteotomy is still the predominant method because of its general reliability, but beyond doubt epiphysiolysis on the lower end of the femur allows better correction of the deformity, being a more central method than the supracondylic osteotomy. Unfortunately, the method of epiphysiolysis is available only in children from five to sixteen years.

Another important principle of modern orthopædic

(a) Address delivered before the New York Academy of Medicine, December, 1902.

surgery is that of absolutely saving the bones by dividing the soft parts as far as circumstances may demand it. This conservatism toward the bones and this radicalism against the soft parts (just the inversion of a principle of former times) condemns all cuneiform osteotomies and resections, of the bones *en bloc*, and makes it a rule to correct deformities by simple linear osteotomy, sacrificing the soft parts as far as may be desirable. Indeed, it is very easy to correct every hip deformity of whatever degree by similar linear (pelvitrochanteric) or central osteotomy, after having thoroughly divided the adductors and the subspinal soft parts. It is of no importance whether you divide them in open wound or subcutaneously, you must only divide them thoroughly. The wedge-shaped excisions of bones in correcting knee contractures are likewise to be avoided, or at least to be restrained to a minimum by regardless radicalism against the soft parts in the fossa poplitea. As to the excisions of bones in the treatment of club foot, I have mentioned, I abhor them.

The principle to correct deformities only by simple linear osteotomy, is even available in those most difficult cases of bow-legs with anterior convexity of the bones. In such cases I apply one or two linear osteotomies to the centre of the deformity, then I add achillotenotomy and sharp screw extension above the ankles until correction is allowed.

Another principle of common interest refers to the treatment of tuberculous diseases of the joints in children, and to the treatment of deformed paralytic limbs. I must avoid discussing the question whether operative or conservative treatment should be carried on in these cases. My standpoint on this question is rather one of expectancy. But I do not hesitate to declare that up to now I have never made a resection of a tuberculous joint in children, and that the results of conservative treatment seem to me far better than those of operative treatment. Nevertheless, I am far from denying the necessity of operating in some special cases, particularly in common hospital practice. However, the principle of which I will speak refers to the question whether or not mechanical treatment should be carried on in a way to exclude all functional work of the limb during the whole treatment. Observation of nature let alone seems to me to give the answer to this question. If we contemplate a case of hip disease never interfered with by any treatment at all, we learn in many cases that nature unhelped by our mechanical means, needs no more time to cure the disease than we do. After some two or three years all may be over. During this time the sick child may have been confined to bed by great pains in the hip joint some months only. During the rest of the time they walk about without the help of crutches as well as they can, using the limb according to the actual state of sensitiveness. After all the disease heals without any suppuration even, and finally we see these children come to us to get rid of their deformity. We find a contracted limb, but fit for function even under the unfavourable mechanical conditions of the deformity. We find the bones solid and the soft parts not so much wasted as we expected; and last, but not least, we find that the growth of the limb has not been much interfered with by the disease. These cases are the best objects for operative treatment because the good state of the legs very soon enables them to profit by the correction of the deformity. If we compare one of these cases of natural healing with the results of our mechanical treatment, which may have begun at the first sign of the disease, we will find that we have scarcely shortened the course of the disease. We have managed that pains have been eased or suppressed, and that the limb may be in a tolerably good position. But surely we shall find the leg in a wasted condition, the muscles being slack, the bones lacking solidity, being quite unable to support the weight of the body, although pains have long since disappeared. Probably we shall find besides that the growth of the leg has been much interfered with by the disease. There can be no doubt that this deplorable condition of the limb is due to the fact that both by suspension and fixation by our

mechanical means the leg has been totally excluded for many years from every function of movement and weight carrying. From this consideration is derived my principle to exclude the diseased limb no longer from a measured function if severe pains will not forbid it. I never allow any movement of the diseased joint, but I suspend the weight only as long as the pains demand it, always taking proper care to procure slight abduction of the leg. As soon as the pains allow it I begin to attend to the muscles by massage. Of the movements, only active and passive abductions are made in the later after-treatment to prevent the tendency to abduction.

My final aim is to procure a solid ankylosis of the hip-joint combined with good position of the leg, experience having taught me that great mobility and bad function with lack of any endurance are common allies. With greatest enthusiasm would I welcome a method which would procure a true bony ankylosis of the diseased hip-joint, bony ankylosis of the hip and good position of the leg being the condition for the best result both from a cosmetic and functional point of view.

As you may have seen by what I have said, I make little of the permanent extension. I consider extension only a matter of fixation, direct and indirect fixation together naturally give a greater degree of surety. I have said that every articulation attacked by chronic diseases should not be prevented from function any longer than is absolutely necessary. In saying so I turn against the method of treatment generally used in Germany, which makes the patients wear their pressure relieving and fixing apparatus so long that they become slaves to them. This same principle I emphasise using in the treatment of paralytic deformities. I am convinced we render no great service to our patients by making them wholly dependent upon their apparatus; the limbs atrophy by exaggerated use of apparatus to such a degree that they become useless for any function. It is my practice to correct thoroughly the paralytic deformities by modelling redressment, in case of need combining the transplantations of the tendons, and to fortify the rest of the muscles by massage and exercises in order to secure the obtained correction. For the rest, the patients, must be accustomed to make use of their legs as much as possible without apparatus, or by assistance of the simplest. Generally, a flannel bandage or laced boot will give the necessary support. In any case I take care to secure the corrected position during the night by means of a simple apparatus. I think that enclosing the leg in a steel support is to be avoided as by so doing the leg will be excluded from any function. On the contrary I try to make the leg independent of mechanical appliances as far as possible. Only in the treatment of total paralysis, which fortunately occurs very seldom, the permanent use of mechanical support is indispensable. In the treatment of scoliosis I am wholly against the exclusive application of mechanical supports, especially against those which are worn day and night. I restrict the use of corsets to special cases which evidently want a support. Besides I take special care of the muscles of the back by exercising them and endorse the necessity of forcible antiscoliotic gymnastics.

Gentlemen, I think it is unnecessary to follow these principles in detail, and I hope you will not object to my endeavouring to solve the problems of orthopædic surgery by operative treatment, and if possible, by a bloodless one, and to restrain and simplify orthopædic appliances.

If the surgical task has been thoroughly solved, orthopædic appliances, if necessary, may be of very simple construction so that special mechanical ateliers may be considered superfluous. If orthopædic surgery conceives and carries out its themes in such a way, then it will be possible to indulge in orthopædic surgery at every surgical station, even if great mechanical means may not be at hand. Then orthopædic surgery will not deny the democratic character which it must have to be able to communicate its progress and im-

improvements to even the poorest children who may be in want of relief.

ERYTHEMA MARGINATUM PERSTANS. (a)

By J. MAGEE FINNY, M.D.Dub.,

Ex-President of the Royal College of Physicians, Ireland; King's Professor of Practice of Medicine in the School of Physic, Ireland, Clinical Physician to Sir Patrick Dun's Hospital.

THE case I beg to report to the Academy of Medicine is one of erythema multifforme, which, from its persistence and its peculiarities, is somewhat removed from the ordinary varieties included in the term, and because of these features I have deemed it worthy of being submitted to the members of the Academy, and have designated it under the title of "erythema marginatum perstans." The patient was exhibited to the Royal Academy of Medicine.

ERYTHEMA GYRATUM AND MARGINATUM OF THE TRUNK AND ARMS.

R. L., a young man, a grocer's assistant, from Banbridge, co. Down, æt. 21, of slight build, and weighing 8 st. 7 lbs., was admitted to Sir Patrick Dun's Hospital on October 13th, 1902, suffering from a skin disease of an erythematous nature, which was said to have been present for over three years.

The lad's hair and face and neck were fair, while the colour of his body and arms, and of his legs in particular, was of a darker hue—more like what a dark-skinned man might present—with a faint metallic yellow-brown lustre. Standing out from the skin were pink-red coloured elevated lines, and

curves and circles and segments and spots, fairly symmetrical in distribution, occupying both the back and front of the thorax, the abdomen, the arms, and the forearms to the back of the wrist, and the nates, thighs and legs as far as the ankles. The palms and soles were free of spots, and the fingers and toes and dorsum of the feet were the only parts exempt. There were a few spots on the back and side of the neck, but the face, scalp, and upper part of the neck were quite free of eruption.

The spots were, some small, quarter-inch in diameter; some large, half-inch; distinctly raised above the skin to both sight and touch, smooth and without any vesiculation; the colour faded a little on pressure. Again, there were coloured rings and irregular circles of half-inch to one and a half inches in diameter, and many of these spaces enclosed by the raised coloured border, were pigmented and covered by the finest scaliness possible, so that they looked as if dusty, and gave the impression that the border was scaly, but closer examination negatived this, as the coloured circumferential border was non-scaly. Again, there were irregular gyrate lines as if formed of two or more broken circles, and, lastly, long lines partly curved

THEMA GYRATUM OF THE THIGH AND LEG.

and partly straight, which terminated abruptly in clear skin. These latter were mostly present in the adductor and extensor surfaces of the thighs, and near the axillæ over the adjoining pectorals.

Further examination revealed the presence of some enlarged glands in the groins and right axilla, and of the right mammary gland. The glands in the neck were normal. A full physical examination showed that all his organs were healthy and all functions were normally discharged, except, perhaps, a little indigestion and constipation. There is no evidence of syphilis, and the lad is a total abstainer. His family history is good.

The following personal history and that of the disease was supplied by the patient himself, who is intelligent, and I read it in his own words:—

"I first took the disease in August, 1899, and, feeling sick, I went home and was attended by the local doctor; on his advice I went into the Banbridge Infirmary on September 9th, 1899, and was there only two weeks under treatment, and left seemingly cured. A week had just elapsed when the skin disease came back, and I was re-admitted to the infirmary, where I remained about seven weeks, and, though a great deal better when I left, the rash was still out on me. I stayed at home until

(a) Read before the Royal Academy of Medicine in Ireland, November 11st, 1902.

the end of January, 1900, and then, on the advice of Dr. Purdon, who had treated me for several weeks, I went into the Skin Hospital in Belfast, and remained under treatment for nine weeks. On leaving, the skin rash was better, but not cured, and I remained at home from April to the end of July, using the ointments I had had while in hospital, after which I returned to business. Except for the month of May, 1901, I have been at business until I came to Dublin, October, 1902. In that month of May I had a very bad cold (influenza?), and during the cold the skin disease came out a great deal more than previously.

During the time at business the skin eruption kept about the same. My legs always were worse than any other part of my body, and if exposed to cold while dressing or undressing would become very hard and of a blackish colour, and they were often swollen about my ankles and even up to the knees. I have had very bad chilblains on my hands the last two winters.

"As to my general health, I have not suffered from any bad illness, but I was easily tired, and perspired very readily. My digestion was bad, as after taking food a quantity used to come up, and my mouth had always a dirty, sticky taste in the mornings, and this continued for a long time in spite of care being taken as to my food, &c.

"The rash or skin disease which is now on me for over three years begins something in the form of a hive, and it then spreads in a ring, the centre becoming healthy-looking, while the ring or border is raised and of a red colour; then one ring meets another, the raised parts blend and spread into all kinds of shapes, and some end in lines either curved or straight. When the inflamed raised parts on my wrists and thighs are much rubbed small watery blebs, about the size of a wart may appear. The skin disease is at times very itchy and especially at night, just like nettle-rash, and I have not been able to resist scratching the spots with my nails sometimes, and have torn them occasionally and made them bleed. The rash has always been worse on my thighs, and legs, and about the knees. My back, shoulders, body and stomach were also covered with the disease; very few spots ever appeared on my face, scalp or neck, and it is only this year that it has come out so much on my arms and backs of hands. Although it has never gone away altogether since August, 1899, it at times was less pronounced, and then again it would return, and though it faded and changed its pattern in one place it would crop up again in another. I do not know any cause for the disease appearing in 1899 in either my habits of living or in my business. I have never had any serious illness, nor am I rheumatic."

To this lucid description I have only to add the results of my own observation while the patient was in hospital.

The eruption, delineated by this painting and these photographs, which latter have been taken by Dr. J. Joly, has been fairly persistent, lasting unchanged for a week or two, and it has been seen to fade in one region while close by to come out afresh. I found the new spots were small papules, and for the purpose of observing their future stages, I enclosed them in a square of aniline ink. In three days they were small circles quarter-inch in diameter, and they were soon seen to reach the enclosing lines and to spread wider and wider beyond

them and to form a distinct circle, and then, as the convex edge approached and touched another similarly spreading circle a breach occurred at the point of contact and the *E. annulare* or *circinatum* became *E. gyratum*, the various shapes of which latter depended upon the sizes of the meeting circles; lastly, some of the large gyrate margins, seeming to exhaust themselves, ended in curved lines forming curious devices with terminals abruptly raised—*E. marginatum*. Except being distinctly raised, they were not at all unlike some tattooing in Egyptian or Hindustani characters. Though I carefully looked for examples of the *erythema annulare* covered with vesicles—the so-called "herpes iris"—I failed to find any, and in like manner I failed to meet a spot of *erythema nodosum*.

Recognising that in all probability arsenic and all the usual remedies had been employed on this boy, and with no lasting good effect, I exhibited the use of thyroid extract; at first in doses of 5 grs. twice a day, and later on three times a day. I was led to think of it knowing its remarkable influence on the cutaneous circulation and the stimulation of the cutaneous lymphatics, and hoped that absorption might be affected of the inflammatory exudation which constituted the disease. During its administration the temperature of the extremities was more evenly maintained, and the induration and swelling of the legs reduced; the patient felt more comfortable, and the larger lines and circles have been more or less absorbed on the back and arms, yet the erythematous and indurated lines on the thighs have not improved, and new papule have continued to appear on the back and shoulders, and rings and gyrate patches have recurred on the forearms and spread down on to the back of the hands, while each new crop of papules, &c., is attended by a very well marked itching. I have therefore discontinued this drug as the results were not sufficiently pronounced, and have substituted for the present syr. ferr. iodid and ol. morrhue.

A few words are necessary on the subject of the diagnosis of the disease.

The peculiar appearance of the patches—pink, red, violaceous—which originally came on as an acute attack in 1899, to be followed by similar exacerbations—the patches appearing first of all as small papules circular in form, fading in the centre as they extended peripherally, assuming shapes of irregular curves or festoons, and of long red curved and zig-zag lines—this protean character of the eruption makes it take its place under the affection which is termed "erythema multiforme." The only missing members of the family group being the concentric rings possessing variegated colours—red, purple, yellow and blue—which is designated *E. iris*, and the solid swellings of the extremities called *E. nodosum*.

The absence of violent itching and tingling and burning sensations distinguish it from urticaria, which it closely resembles, while the eruption is more pronounced in colour and form, is more persistent, and there is an absence of wheals.

When first seen on the thorax it slightly resembled the circinate and gyrate rash of psoriasis, a drawing of which I submit, but besides its own characteristics, described above, it lacked the two well-marked features of psoriasis, viz., (1) the bleeding points one finds on attempting to scrape

away the spots; and (2) the heaped-up epidermic scales peculiar to the latter disease.

It had nothing in common with eczema—even the variety “eczema papulosum,” from which the absence of very severe itching, the large size of the papules, and their irregular shape and form sufficiently distinguish it; while from “dermatitis herpetiformis” the absence of vesicles and bullæ sufficiently remove it. There were a few vesicles discoverable on one or two of the red lines on the wrists while under hospital supervision, and the patient reports that he had noticed a little moisture to exude occasionally from them when much rubbed, but I feel confident this disease is excluded, for while some cases of *D. herpetiformis* have an erythematous and urticarial phase, it is essentially a vesicular or bullous disease, and includes such conditions as “herpes gestationis,” “hydro a æstivo,” or “hydroa vaccini-forme,” &c.

The chief resemblance between the two diseases, that is, erythema multiforme and dermatitis herpetiformis, seems to lie in the disposition to group and to extend about the periphery. Dr. Payne showed a case before the Dermatological Society of London in 1898 which he described as “erythema gyratum,” but which seemed to have been one of the erythematous stages of dermatitis herpetiformis in the subsequent opinion of himself and Drs. Crocker and Malcolm Morris.

I shall quote the published extract in the “Transactions” (p. 142) as it strongly resembles my case, and it is possible that even in contradiction of the above specialists’ opinion, Dr. Payne’s case was one of erythema multiforme, and not of dermatitis herpetiformis.

“A man, æt. 45, presented an eruption, which had lasted sixteen months, and which consisted of erythematous patches varying in size up to some inches in diameter, the larger being distinctly annular or marginate, with a raised, red, somewhat hard margin. The smaller were discoid. Some patches were persistent for a long time (weeks?), others more transitory, and new patches appeared from time to time. The eruption was generally distributed on the covered parts of the body, but absent from the face and hands. A few spots showed traces of a ruptured vesicle, and the itching was at times very great. The lymph glands all over the body were enlarged and hard, especially in the groin.” A subsequent report stated “that under full doses of quinine (15 grs. a day) the patient recovered.”

Recognising that the case I have reported was out of the ordinary run of cases of erythema, I made search for the description of any cases of erythema which could tally with it, and consulted all the text-books on skin diseases, including the latest, by Stellwagon (1902), but with little success. In my search through the volumes of *The British Journal of Dermatology* I came across two instances, in addition to that of Dr. Payne’s, which may be somewhat similar to mine. (a) In Vol. III., p. 24, Dr. Abraham exhibited a woman with erythema perstans affecting the hands, but no notes are recorded. (b) In Vol. IV., Dr. Saville gave the notes of a case of a woman, æt. 35, whom he exhibited to the Society. She had had a first attack five years before, lasting two years, and a second attack, after an interval of nearly three years during which she was quite well. The erythema came out first on the hands and feet, as a slightly raised flat eruption, which in two days became a circle of two inches

diameter; the margin was raised, there were no vesicles or scales, with itching at night. Then the rash appeared on the dorsum of the feet, similarly raised, as red circles and segments. Dr. Saville considered it a variety of erythema multiforme, and its nature seemed unknown to the members of the Society present.

I also searched the volumes of the *American Journal of Cutaneous and Genito-Urinary Organs*, and was so far rewarded by finding one case, and one case only, somewhat closely resembling mine in some of its features. It is recorded by Dr. Lustgarten before the New York Dermatological Society in 1893, Vol. XI., p. 110, under the name erythema papuatum, vel circinatum figuratum, perstans, et chronicum.

A man, æt. 21, was struck by a horse on his head, and, two months after having been trephined, an eruption came out on his body and lower extremities in annular or gyrate patches with elevated borders, remaining for weeks and months, and leaving the skin pigmented. New patches were being constantly added, with slight itching and unaccompanied by any other subjective symptom; all medicines employed seemed useless. Dr. Lustgarten considered it a reflex neurosis of traumatic origin.

Dr. Walter G. Smith has since called my attention to a paper read before the Clinical Society of London by T. Colcott Fox, M.B., November, 1880, which details two cases of erythema gyratum perstans in a brother and sister, æt. 19 and 18, which had lasted, with remissions and quarterly exacerbations, since they were four years of age, with a drawing affixed (life-size copy is in the Royal Atlas of Rare Skin Diseases); and in every feature these cases seem to resemble my case. Steel and cod-liver oil, after a prolonged course, seemed to do them good.

A passing comment is necessary on the involvement and enlargement of the glands in the groin and in the right axilla, which may be considered a feature of an unusual character.

The only allusion to this complication is quoted in “Stellwagon’s Diseases of the Skin” (p. 197) as being Jarish’s view that the swelling of the lymphatic glands, especially the cervical, has been sometimes noted in erythema multiforme.

In conclusion, I have to thank the Academy for its patient hearing, and to offer my apologies for having occupied so much of their time in portraying the features of this case.

I trust some members present may have seen similar cases, and that they may be able and willing to assist me on the question of treatment.

Clinical Lecture ON THE ART OF EXTRACTING FOR CATARACT. (a)

By C. BELL TAYLOR, M.D.,

Surgeon to the Nottingham and Midland Eye Infirmary.

I HAVE here a patient on whose right eye I operated for cataract in his eighty-sixth year, and on whose left eye I operated for cataract in his ninety-sixth year; as you see, the pupils are central and he can read for hours and tell the time by the Exchange clock.

I also have here another patient, æt. 60, both

(a) Delivered before the Nottingham Medico-Chirurgical Society, 1902

of whose eyes I operated upon for cataract by extraction four years ago. On his recovery from the operation he obtained employment as a smith in the furnace department of one of our principal railways, and has since been exposed day by day as a striker to the very trying glare of incandescent metal; nevertheless, you will note that both eyes are perfect, I may say, without exaggeration, singularly beautiful, that sight is excellent, that he does not require to wear glasses, and that all trace of surgical intervention is conspicuously absent.

The cases of *double* extraction for cataract, to which I had the honour and pleasure of calling your attention a few evenings ago, although operated on within the last few weeks, were equally remarkable in result and equally free from all trace of operative interference. Now I need not tell you that this is the perfection of art, *i.e.*, to conceal art, and I propose to-night to lay before you some of the reasons by which I was led to the adoption of a method of treatment which has yielded such satisfactory results.

When Professor Waldau, the late von Graefe's assistant, whose practice I followed in Berlin, proposed to excise a small piece of iris and then to scoop out cataracts with a spoon, he did so because, although at that time suppuration was by no means rare after cataract extraction, it was almost never observed as a result of simple iridectomy. It occurred to me that a slight enlargement of Waldau's incision would enable us to dispense with that very objectionable instrument—Waldau's steep-edged spoon—and later on, seeing the vast importance of maintaining a perfect screen and a central and movable pupil after ablation of the lens, I determined to enlarge Waldau's incision still further, and to dispense not only with the spoon but also with iridectomy. Waldau made his incision with a broad trowel-shaped keratome, entered at the summit of the cornea precisely in the corneo-sclerotic junction. I have attained the same end with greater facility and absolute precision by substituting one or other of the knives depicted in actual size below.

No. 1 for the Right Eye.

No. 2 for the Left Eye.

In performing this operation it is necessary to separate the lids with a light speculum, easily displaced, to steady the eyeball with forceps which perforate the sclerotic, and to enter the knife, which should be in first-class condition both as to point and edge, in the cornea close to the sclerotic junction, at the base of a flap which, when completed, will comprise nearly if not quite one-half of the cornea. The knife is then pushed quickly across the anterior chamber until it emerges at a counter puncture similarly placed, sawed, if I may be allowed the expression, rapidly upwards, so as

to get in front of the iris, which would otherwise fold over the edge of the blade, and then turned forwards so as to complete the section precisely and deliberately in the upper border of the corneo-sclerotic junction. In this way a flap is formed which fits like a watch-glass, so precisely that the wound is invisible the moment the knife is withdrawn, which is at once agglutinated to adjacent tissues, and which ultimately leaves no trace. I prefer to lacerate the capsule widely, but only in its periphery, as suggested by Knapp, and always do this part of the operation with a very light hand, lest the lens be displaced or cortex separated or a portion chipped off. If now slight pressure be made at the lower border of the cornea or if the patient looks down, the wound will gape, the lens will present at the pupil, which it slowly dilates, performing a movement of bascule, and then emerges *totus teres*, and if not *atque rotundus*, at all events with an unbroken surface, the flap falls automatically into its place, and if all has gone well there will be no cortex to squeeze out (because there has been none separated from the nucleus) and no prolapse of the iris (because it has not been unnecessarily strained during the passage of the lens) or other trouble then or after to vex the soul of the operator or disturb the serenity of the patient. If the wound does not gape on slight pressure or when the patient looks down—and here is the crux of the whole matter—it is because the incision is not large enough or the wound has been wasted by cutting between the layers of the cornea instead of entering the chamber at once, in which case it, the wound, may be enlarged by curved, blunt-pointed scissors adroitly manipulated; if it still does not gape on pressure there is some complication or deviation from natural conditions which will have to be met *secundum artem*, or the eyeball may be closed for a season, and the experience gained be utilised to the benefit of both patient and operator on some future occasion. I will not detain you now with details on these points. What I wish to emphasise is that the operation I have described is differentiated from all others by the extremely narrow knife, as narrow as narrow can be, with a deep shank for the left eye by which the right hand may be used for the left eye and the necessity for ambidexterity on the part of the operator dispensed with; by the large easily gaping wound limited to the corneo-sclerotic junction and differing but little in size from Daviel's of 150 years ago; by the consequent complete evacuation of the lens and cortex, so obviating prolapse of the iris, and by results which are certainly beyond compare. Indeed, there can be no question that such patients not only look better and see better (the contractile pupil replacing accommodation and compensating as in aphakial animals) for the loss of the lens, but that they are much better able to bear the brunt of life (witness the smith I have just introduced to your notice) and much less liable to any ulterior ill-consequences than if they had been operated on by one or other of the combined methods which have been so fashionable of late years.

When operating, I stand behind the patient, who is reclined, and I almost invariably use artificial light. The chimney of the lamp which some of you have seen me use for extraction in this room is an excellent steriliser, and the knives, curettes, and prickers may be soaked in absolute alcohol, while the patient's face, especially the eyelids and roots of the lashes, are sponged with the same fluid.

Cocaine and holocaine in the vast majority of cases suffice for anæsthesia, but if the patient prove very refractory, as now and then happens, ether nebulised by nitrous oxide may be given, or ether alone may be administered by the thermogen inhaler or a modification of the cone, both of which prevent freezing, and are in my opinion far superior to Clover's or any other apparatus of the kind. The patient should be got quickly under by the exclusion of air and the operation commenced at once during the first period of ether anæsthesia, in which case, according to my experience, you will seldom have sickness or subsequent trouble of any kind. I may mention that I have on several occasions

demonstrated what I believe to be the advantages of the operation I have described. I have, for instance, exhibited cases of double extraction at the Clinical Society of London, again at the Royal College of Physicians, when the International Ophthalmological Congress met there, again at the Royal Ophthalmic Hospital, Moorfields, when the late Sir William Bowman declared that the results of my operations "left nothing to be desired," and more recently I have submitted a number of cases to the criticism of the members of the Ophthalmological Society of the United Kingdom, at their rooms, Chandos Street, London.

Mr. President and gentlemen, I have endeavoured to treat a big subject in a very few words and a very small space. Some important details with regard to complicated cases are necessarily omitted, but I hope I have said enough to be understood, and as I number my cases of extraction by the thousand and am constantly operating, I hope I shall not be deemed presumptuous in placing the results of my experience at the disposal of my distinguished colleagues and the members of this learned Society.

A sum of £10,000 has been vested in trustees by Mr. T. Sutton Timmis, J.P., for the purpose of initiating systematic investigations into the origin and cure of cancer. The investigations will be carried on at the Liverpool Royal Infirmary, and the new laboratories of experimental medicine in University College, Liverpool.

A NEW FORM OF NASAL TRUSS.

By W. J. WALSHAM, M.B., F.R.C.S., &c.
Surgeon to, and Lecturer on, Surgery, St. Bartholomew's Hospital.

HERETOFORE, the difficulty has been to prevent the forehead plate of a nasal truss from slipping from side to side and upwards over the forehead. The present truss is designed to obviate this difficulty, by making the lower border of the forehead plate follow the contour of the root of the nose and contiguous orbital

margins. A rounded notch (A) corresponding with the root of the nose is cut in the plate and the margins of the lower part of the plate forming the sides of the notch are bent backwards in a blunt curve (B B) to almost a right angle to the rest of the plate. The notch, therefore, embraces the root of the nose, while the turned back portions of the margins of the plates catch under the orbital ridges at the internal angular processes of the orbits. This prevents the truss from being displaced upwards, while the notch prevents any movement from side to side. The truss is provided with the usual straps and headband, and to the plates are fixed the usual arms for making pressure upon and fixing the nasal bones or cartilages.

It is made by Messrs. Arnold and Sons, West Smithfield, London.

Clinical Records.

THE MIDDLESEX HOSPITAL.

A Case of a Large Sarcoma of the Uterus Removed by Abdominal Hysterectomy; Bladder laid open; Recovery. (a)

By WILLIAM DUNCAN, M.D., M.R.C.P., F.R.C.S., &c.,
Obstetric Physician to the Middlesex Hospital.

THE patient, æt. 56, was admitted into Prudhoe Ward of the Middlesex Hospital on September 26th, 1902, complaining of increasing size of the abdomen, swelling and pain of the legs, with progressive emaciation and weakness for the last twelve months.

Family History.—One sister died of "flooding" at the age of 42, and her grandfather is said to have died of cancer; nothing else of importance.

Previous History.—The patient had rheumatic fever twenty-five years ago. Has been a widow for six years after twenty-four years of married life, during which she was only once pregnant, nine months after marriage, and she then "miscarried." The catamenia began at 15½; were always regular, lasted six days and the loss was rather scanty. The menopause occurred eight years ago without any trouble. Ten years ago she complained of pain in the right iliac fossa, was examined by a medical man, who found a small lump there; this swelling has gradually increased in size until six months ago, since when the increase has been rapid, and the patient has appreciably lost flesh and strength. She has lately suffered from indigestion and frequency

(a) Read at the British Gynæcological Society, January 8th, 1903.

and slight difficulty in micturition. No constipation.

State on admission.—The patient is a pale, emaciated woman. The abdomen is greatly enlarged (more than at a full-term pregnancy), the skin is tense and distended, marked by superficial veins coursing over it and presenting red pigmented spots, "tâches de Morgan." On palpation, the abdomen is found to be occupied by a tumour which is solid in some parts and cystic in others; rather uneven on the surface. No thrill to be felt, nor anything abnormal on auscultation.

Per vaginam.—Os uteri is felt high up; cervix small and closely connected with a mass which dips into pelvis from above; sound not passed. The history and clinical features pointed to an ovarian tumour, probably undergoing malignant change.

Operation on October 2nd.—The patient having been anaesthetised with gas and ether, a median incision was made between the umbilicus and pubes; the tumour was seen to have huge veins coursing over it, and in places the bowel and omentum were adherent. The incision was then extended up to the xiphoid cartilage in order to thoroughly examine the connections of the growth and to decide on the advisability or otherwise of proceeding with the operation. It was evident that the tumour occupied both broad ligaments, but owing to its size and the universal adhesions it was impossible to say definitely where it sprang from. Having decided to proceed, I began to detach the adherent gut and omentum. Whilst doing this I laid open (in the middle line and above the level of the umbilicus) a cavity from which escaped some clear odourless fluid. Thinking it to be a cyst, I opened it down to the extent of about six inches, and then found it was the urinary bladder. Having separated this viscus from the surface of the tumour, I carefully closed up the opening I had made by means of a series of silk sutures passing through all the bladder coats. I also put in a few fine silk stitches through the peritoneal coat alone. The fundus of this greatly elongated bladder I fixed to the abdominal wall, just above the symphysis pubis, with a silk suture. Finally, after a most difficult operation, I got the tumour out of the abdomen and having tied all bleeding vessels, cut across what proved to be the cervix uteri, leaving quite a small stump of the cervix. By uniting behind the posterior layer of each broad ligament I formed a cavity large enough to hold an adult head. At the bottom of this was the small stump of the cervix. The upper margin of the cavity in the broad ligaments was next sutured to the lower end of the abdominal incision, leaving an opening through which the cavity was loosely stuffed with iodoform gauze. The remainder of the abdominal wound was then closed with three layers of sutures, and dressings applied in the usual way. The amount of blood lost was not much, and the patient stood the operation (which lasted one and three-quarter hours) well. The urine was ordered to be drawn off every three hours, so as to prevent any chance of distension of the bladder.

The patient made an uneventful recovery. For the first three or four days the urine was bloodstained, but then became normal and was passed naturally after five days. At first there was a good deal of blood-stained oozing from the gauze filling the cavity in the broad ligaments, but this got gradually less, and the cavity steadily contracted, so that the amount of gauze used became less and less until at last only a small sinus remained, and the patient was sent to the convalescent home at Clacton-on-Sea on October 30th, five weeks after the operation.

Remarks by DR. DUNCAN.

This case presents several points of interest.

1st. Difficulty of diagnosis.—It seems to me that it was quite impossible to give a positive diagnosis in this case (as it is in so many others) until the abdominal cavity had been laid open. There was no history of uterine trouble; the tumour began, or was first felt, in the right iliac region; it had the characteristic feel of a multilocular ovarian. Even after the abdominal cavity had been freely laid open, I was unable to say where the tumour sprang from. When removed it

weighed thirteen pounds, but it was now very much contracted.

2nd.—The opening up of the bladder was due to its having been so closely adherent to the tumour and dragged up above the level of the umbilicus. Opening the bladder during the course of removal of uterine or ovarian tumours is not, I believe, a very uncommon accident. Personally, I have always been very careful to try and avoid doing so, and this is my first experience in my own practice of this accident. When it does occur, what is the best treatment? This subject has been thoroughly discussed by Dr. Charles Greene Cumston, of Boston, in a paper entitled "Lesions of the Bladder during Abdominal and Vaginal Hysterectomy," which appeared in the *Boston Medical and Surgical Journal*, November 21st, 1901. Dr. Cumston kindly sent me a month ago a reprint which I only wish I had read before the accident just related occurred. There are numerous methods of suturing the wounded bladder, but Dr. Cumston advocates two layers of sutures—a catgut suture uniting the mucous membrane and a second Lembert suture (also of catgut) uniting the other coats. He also says that if the rent be a long one, it is advisable to put in a third layer, uniting peritoneum alone. Dr. Cumston lays great stress on the importance of putting a self-retaining catheter into the bladder for about ten days, and changing it every four or five hours for a fresh one. This advice appears to me sound, and if it should be my ill fortune to again open the bladder during an operation I should follow Dr. Cumston's method, even though in the case I have recorded no ill-effects resulted from passing a catheter every three hours.

3rd.—When a cavity is left after the removal of a tumour from between the layers of the broad ligament, my usual method is to obliterate that cavity at the time of operation by whipping the sides of the cavity together from below upwards by a continuous suture and thus obtaining immediate union, instead of packing the cavity with gauze and letting it slowly contract up. In this case, however, the cavity left by the opening up of both broad ligaments was so large that I had no alternative left but to adopt the slower method..

Lastly.—With regard to the tumour itself: Owing to the sarcomatous masses being encapsuled, there appears to be a much better chance for the patient escaping recurrence. I wish that I had removed the small bit of cervix still remaining. The patient, as far as I am aware, continues well, but it is yet too early to say whether she will recover completely.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.
MEETING HELD JANUARY 8TH, 1903.

SIR J. HALLIDAY CROOM, F.R.C.S., F.R.S.E., President,
in the Chair.

THE report of the Editor of the *Journal* of the Society was read and adopted on the motion of Dr. HEYWOOD SMITH, seconded by Dr. BEDFORD FENWICK, the thanks of the Society being at the same time voted to Dr. J. J. Macan for his services.

The officers were elected for the current year. The list will be found under "News."

Dr. MACNAUGHTON-JONES read notes of—
CASE OF TWINS AFTER SALPINGO-OOPHORECTOMY AND RESECTION OF THE OTHER OVARY.

The patient, æt. 26, who had had five pregnancies, with labour at full term, first consulted me three years since. She was then suffering from all the symptoms attendant upon chronic suppurative endometritis. There was a very profuse discharge with an extensive and deep cervical erosion. She had been treated for the erosion and endometritis for some time before I saw her. Both ovaries were enlarged and painful, the left especially so. The uterus was subjected to most thorough curetting with the application of chromic acid

internally, and nitric acid to the eroded surface, the result being a complete cure of the endometritis and erosion. Pelvic pain, however, still continued, with difficulty of locomotion, and on February 21st, 1901, I removed a large cystic ovary with a thickened and dilated tube, and resected the other, which was studded with small cysts. She quickly recovered from the operation, but for some time the course of the case was not very satisfactory, as she still complained of pelvic pain, and there was sensitiveness of the remaining ovary. However, on June 4th, 1902, she was confined of twins under the care of Dr. Frederick Evans of Cardiff. Her labour was a very quick one. The sex of both children was female, and there were two amniotic sacs, and two placentæ.

REPEATED PREGNANCIES AFTER SALPINGO-OOPHORECTOMY AND VENTROFIXATION OF THE UTERUS.

The following notes have been supplied to me by Dr. William Bourke:—"Patient, æt. 26, consulted me in April, 1897. Ten weeks after marriage she had had an accident causing miscarriage, for which she was casually treated, being in bed for two days only. Since then she has never been well—sacral aching, fatigue, great pain before and during the periods, walking producing much pelvic distress. Had consulted two specialists. One put her under the 'rest' cure; the other told her to forget her pain and take a long sea voyage. Her husband took her to Australia, and she suffered much increase of trouble during the voyage, and was entirely laid up in Australia. She came home as soon as she could travel, much the worse for her trip. Six months after this she consulted me. I found a retroflexed uterus with the left ovary in Douglas's pouch, swollen, not movable, and very tender. Finding it impossible to keep a pessary of any kind in the vagina, and no good resulting from palliative treatment, I advised operation, but was overruled by three consultants consecutively. I then treated the unhealthy catarrhal state of the os and cervix in the hope of producing conception, which fortunately occurred, and I safely delivered her at full term. In spite of every precaution, after delivery the uterus returned to its former position, and the ovary continuing to give trouble, life became a burden to her. I again advised operation, and had consultations with three other specialists, who were not in favour of it. I told her family that it was useless to try to do more, and there appeared no alternative save chronic invalidism." At Dr. Bourke's request, I saw her in October, 1899, and operated on November 8th, removing the left ovary and performing ventro-suspension. Dr. Bourke summarises the result in the following words:—"The result has been perfect from a surgical, exceedingly so from a matrimonial point of view, for the patient has been twice confined at full term of healthy children, without the smallest complication. A third conception, however, ended in a miscarriage." The uterus has all through maintained its normal position.

The PRESIDENT mentioned an instance in which conception and miscarriage followed the complete removal of both ovaries by himself; the possibility of a third ovary suggested itself.

Dr. MACNAUGHTON-JONES said that in the first case only about one-third of the second ovary had been removed, and, in reply to a question of Dr. Heywood Smith's, that he had, as was his custom, used prepared gut for ligature.

Dr. WILLIAM DUNCAN exhibited a large sarcoma of the uterus, and read notes of the case which will be found in another column under the heading of "Clinical Records."

Dr. BEDFORD FENWICK said that in operating upon a large tumour which dragged the bladder upwards it was very difficult to avoid wounding that organ. A very useful precaution, always adopted at the Soho Hospital whenever there was any question of the bladder being so displaced, was to pass a sound, and make sure of its position. When a cavity in the broad ligaments was left too large to be entirely obliterated, he, and some of his colleagues, had found it well to whip the edges together so as to completely shut the

vacant room in the broad ligament off from the peritoneal cavity, and then to make an opening from the vagina; the vacant space then collapsed downwards, and the healing was very much more rapid, the abdominal wound not being disturbed.

Dr. HERBERT SNOW thought that Dr. Duncan was to be congratulated on his success in dealing with a very difficult case. The existence of the tumour for ten years seemed to point to its being an instance of malignant degeneration of a primarily innocent fibroid; the specimen under the microscope clearly showed its sarcomatous nature. It was a matter of regret that one could not distinguish between myo-sarcoma and true sarcoma produced from connective tissue; he doubted whether the latter ever attacked the uterus; though it might spring from the broad ligament, ovary or tube.

Mr. BOWREMAN JESSETT concurred with Dr. Fenwick as to the advantage of vaginal drainage. It was the usual practice at the Cancer Hospital, and they found that generally the top of the cavity closed down in two or three days, and that a few days later the gauze drain could be safely removed. He had, to his regret, opened the bladder once or twice by accident; he had sutured the mucosa with catgut and then stitched the peritoneum in Halsted's way, which he preferred to Lembert's; he had found one layer of sutures, in addition to those uniting the mucosa, sufficient. In one instance, in which the tumour weighed sixteen pounds, he had had the misfortune to find at the last moment, after the tumour had been removed, that the ureter had been divided in two places; as he could not detect the upper end, he concluded that it had been included in a ligature, and that the kidney would atrophy, but the case ended fatally. In all vaginal hysterectomies he adopted the plan of leaving a self-retaining catheter in the bladder for the first two days, with the end led into a male urinal between the patient's legs; this kept the bladder empty, and saved the patient the worry of having an instrument passed every four or six hours; this plan he also adopted in cases in which the bladder had been injured. He asked Dr. Duncan whether the patient had had no cystitis or other bladder trouble before the operation.

Dr. MACNAUGHTON-JONES thought that the precaution of passing a sound into the bladder ought never to be omitted in any case of hysterectomy. He had had the misfortune to open the bladder once in removing a giant myoma; he closed the aperture, which was not a small one, by a single layer of suture, introduced a self-retaining catheter, and the woman recovered perfectly. After such an accident there was apt to be some bleeding into the bladder. In the case just mentioned he had given adrenalin to control such hæmorrhage, yet nearly a fortnight afterwards the patient passed an organised clot by the urethra. Nevertheless, he thought such coagulation might be less likely to occur when the urine was allowed free and constant discharge through a self-retaining catheter. Coley had given several instances of elevation of the bladder by a tumour unaccompanied by any vesical symptoms, and one in which he removed a portion of the wall as large as the palm of his hand; yet the woman got perfectly well. He saw no advantage in vaginal drainage of such a cavity as that described, provided perfect hæmostasis had been secured.

Dr. DUNCAN, in reply, said that the passage of a sound was undoubtedly a valuable proceeding, but he could not agree with Dr. Bedford Fenwick as to the advantage of vaginal drainage, which he considered, unless there was danger of the accumulation of blood in the cavity, introduced an unnecessary element of danger from infection. As to the tumour, in the recent condition it resembled a myoma, and he quite agreed with Dr. Snow and Mr. Jessett that a sarcoma could not have been going on for ten years, and that the case was one of secondary malignant degeneration. He was not inclined to use a self-retaining catheter in vaginal hysterectomy, but admitted that it might have been wiser to introduce one in this case. Of the ureters he had seen no more than their openings into the bladder.

The patient, when particularly questioned, said she had had slight frequency and also difficulty of micturition, but she had not volunteered any complaint of vesical trouble.

Mr. BOWREMAN JESSETT showed a specimen of an Ectopic Gestation removed about two hours previously from a patient supposed to be suffering from obstruction of the bowels for the past five days. When he first saw her at 2.30 p.m. she had begun to vomit and presented all the symptoms of her supposed condition. At 5 p.m., provided with a Paul's tube, he made an incision for a cœlio-colotomy, proposing to open the colon and insert the tube, and afterwards deal generally with the bowel, but directly he opened the peritoneum an enormous quantity of black venous blood gushed out. Introducing his hand, he turned two quarts of blood-clot out of the pelvis, and, to his astonishment, found an ectopic gestation in the left broad ligament, which he was able to pull up, ligature on both sides, and remove, but it took him three-quarters of an hour to stop the bleeding. The intestines were enormously distended, came out in a body, and greatly impeded the operation. A long tube passed up the rectum removed much of the flatus from the ileum; to relieve the jejunum he had to make an incision, which he sewed up again, and then returned the bowels into the abdomen and closed the wound. The patient, æt. 36, had not been pregnant for nine years, and it was not until after the operation that it was ascertained that she had missed one period. She had complained of umbilical pain for nine days, and probably the hæmorrhage had been going on for that time. The case was a very unusual one, as there was nothing to lead him to suspect a pregnancy; he hoped to report further upon it at some future date.

The President, Sir J. HALLIDAY CROOM, then delivered his Valedictory Address, which we hope to publish in our next.

A vote of thanks to Sir J. Halliday Croom for his services in presiding over the Society during the past year, and for his very interesting address, was proposed by Dr. MACNAUGHTON-JONES, seconded by Mr. BOWREMAN JESSETT, and carried by acclamation.

THE LARYNGOLOGICAL SOCIETY OF LONDON. MEETING HELD FRIDAY, JANUARY 9TH.

The President, Mr. E. CRESSWELL BABER, in the Chair.

The following officers were appointed for the year:—Dr. P. McBride, president; Mr. A. A. Bowlby, Dr. J. Dundas Grant, Dr. P. Kidd, Mr. C. J. Symonds, vice-presidents; Mr. W. R. H. Stewart, treasurer; Dr. StClair Thomson, librarian; Dr. J. Donelan and Dr. E. Furness Potter, secretaries; Sir Felix Semon, Mr. E. Cresswell Baber, Mr. C. A. Parker, Dr. W. Permewan, Mr. R. Lake, and Mr. L. A. Laurence, members of the council.

Sir FELIX SEMON showed a case previously exhibited at the November meeting of the society, of ulceration of the left tonsil with enlargement of numerous cervical glands, in a man, æt. 70, on both sides of the neck (malignancy?). It was now seen that the ulceration had quite disappeared, and the tonsil had become much smaller, whilst the enlargement of the cervical glands had considerably diminished. Malignancy was now completely excluded. The case was shown again as affording valuable evidence that ulceration of a tonsil in old people with enlarged glands must not necessarily be looked upon as malignant.

Dr. P. WATSON WILLIAMS exhibited new design for sphenoidal sinus, cutting forceps, and a laryngeal spray.

Dr. A. BROWNE showed a drawing and read notes of a case of "Suppurative Ethmoiditis and Frontal Sinusitis," after radical operation for nasal polyp. The case had been cured on three occasions with Meyer's ring-knife. Four weeks after the last operation the patient began to have pain, a high temperature, and became semi-comatose. The nose and forehead became swollen. Both frontal sinuses were opened and found to be full of pus. The dura was exposed. The patient was relieved for twelve hours after the operation and then died. The anterior part of the left frontal lobe

was found to be necrosed, and there was extensive purulent basal meningitis.

Dr. H. L. LACK showed a man, æt. 59, with aphonia of six months' duration, who had a similar attack last year. He spoke as if the glottis were closed, but could sing with a natural voice.

Dr. McBRIDE was of opinion that this case was one of spastic aphonia.

Dr. LACK also showed a microscopic section from a large ulcer of the tonsil in a man, æt. 25, showing (?) tubercles. There was no history of syphilis, but the case yielded immediately to iodide of potassium.

Dr. LACK also showed a microscopic section of cyst of ventricle of larynx opened when operating on a case of malignant disease of the larynx.

Mr. R. LAKE showed specimens shewing a new growth of the inferior turbinal (1) of posterior extremity in a male, æt. 52; (2) of septum and inferior turbinal in a male, æt. 28; and (3) of inferior turbinal in a patient, æt. 72 (an old lapsus case).

Dr. H. TILLEY showed a case of large hypertrophy of mucous membrane in the ary-tænoid region (so-called inter-ary-tænoid pachydermia) in a robust-looking man, æt. 48.

Dr. J. DONELAN showed a specimen of large naso-pharyngeal fibro-myxoma with prolongations extending to the anterior nares in a youth, æt. 18.

Dr. BARCLAY BARON showed a case of "Naso-pharyngeal Malignant Disease" in a man, æt. 50. The patient had complained of deafness and nasal obstruction and discharge of blood and pus from the nose for about eight months. Three months ago a hard, irregular growth had been removed by scraping from the naso-pharynx, with relief of all symptoms. The symptoms had again returned and the naso-pharynx was filled with growths which protruded into the nostrils. The nature of the growth was uncertain, but in places it had the appearance of lympho-sarcoma.

The President, Dr. McBride, Mr. Spencer, Dr. Tilley, and Dr. Pegler discussed the case.

Mr. ATWOOD THORNE showed a case of epithelioma of the larynx in a man, æt. 60. There had been hoarseness for six months previously. The left cord was seen to be fixed in the middle line, and the growth observed involving the left ary-tænoid and ary-epiglottic fold. There was slight tenderness to external pressure, and a large gland under the ramus of the jaw on the left side. There was no history of syphilis. Potassium iodide had been given for the last fortnight, but with no appreciable result. The case was discussed by the President, Dr. Lack, Sir Felix Semon, Mr. Waggett, Dr. Dundas Grant and Dr. McBride. The opinion expressed was that the case was not suitable for operation.

Dr. FITZGERALD POWELL showed a case of infiltration of the pharynx and post-nasal spaces in a man, æt. 45, probably syphilitic. Dr Powell also showed a growth in the post-nasal space appearing below the soft palate in an infant æt. 18 months, for diagnosis.

Mr. W. G. SPENCER showed a case of symmetrical swellings of gum at the hinder end of the alveolar border of each upper jaw in a woman, æt. 37.

Dr. W. H. KELSON showed (1) a woman, shown at a previous meeting, suffering from aphonia due to a rounded growth originating in the left ventricle, which prevented approximation of the cords. He had removed the growth, and specimens shown under the microscope pointed to its being a fibroma undergoing mucoid degeneration.

Dr. KELSON also showed a case of recurrent fibrous polypus of the nose in a man, æt. 26.

Dr. DUNDAS GRANT showed a case of chronic laryngitis with inter-ary-tænoid pseudo-pachydermic swelling probably due to purulent rhinitis, in which the hoarseness had much diminished, and the inter-ary-tænoid had become smaller during the use of a nasal wash for one week.

Dr. DUNDAS GRANT also showed a case of hereditary specific perforation of the left anterior pillar of the fauces.

**CORK MEDICAL AND SURGICAL SOCIETY.
MEETING HELD ON WEDNESDAY, JANUARY 14TH.**

Dr. P. T. O'SULLIVAN, President, in the Chair.

THE PRESIDENT showed a man, *æt.* 27, suffering from compression of the spinal cord, as a result of "tubercular disease of the vertebra." The patient had suffered from angular curvature since childhood, but the present symptoms had shown themselves only for the past few months. There were pains in the back and in the intercostal region, and within the past few weeks paraplegia had developed. There was no bladder trouble. The deep reflexes were increased, and ankle-clonus could be obtained. He proposed trying extension for the present, and subsequently a plaster-of-Paris jacket.

Dr. C. YELVERTON PEARSON read notes of a case of successful operation on a patella fractured for the fourth time. The patient was a young man, *æt.* about 30, the subject of osteoporosis. He had sustained over a dozen fractures at different times since childhood, the long bones being usually involved, and some of them having been fractured several times. The patella was found to be very porous. After passing a very fine bradawl he introduced two sutures of silver wire diagonally, not touching the articular surfaces, and then put up the limb in plaster-of-Paris for three weeks. On removing the bandage the patient had good movement in the limb, and had further improved since then.

Dr. T. GELSTON ATKINS showed three specimens of "uterine tumours removed by panhysterectomy." The first was a case of adeno-carcinoma. The patient progressed favourably for nine days after the operation, but then developed acute delirious mania, to which she succumbed six days later. The second specimen was a round-celled sarcoma, and the patient in this instance made a good recovery. The third specimen was a very large myoma. Three weeks after the operation, on the evening previous to her intended discharge from hospital, the patient died quite suddenly, probably either from thrombus or from fat-embolism.

PARIS, January 18th, 1903.

PARALYSIS OF DIPHTHERIA.

At the meeting of the Société Médicale, M. Aubertin spoke of the paralysis so frequently observed after an attack of diphtheria, which he attributed to a kind of slight neuritis uninfluenced by the injections of serum, as he had found in four cases in which he tried this. M. Comby said that for his part he could not do otherwise than recommend serotherapy for that kind of paralysis, as it was a rational treatment and could do no harm.

SUPPURATIVE TONSILLITIS.

Everyone knows how very distressing quinsy is, and those who suffer periodically from it are ready to appreciate any treatment that will abridge their torture. Up to the present and for ages past palliatives externally and local internal applications constituted about the limit of our therapeutics. Belladonna ointments and poultices externally, fumigations of mucilaginous substances, painting the surface with cocaine (more or less dangerous) was the treatment generally prescribed, with salol or salicylate of soda given internally from the presumption that the painful affection was due to an arthritic diathesis. In spite of the intelligent combination of remedies and an earnest desire of the physician to alleviate the suffering of the patient, the malady ran its course in nine days and relief only came when the abscess burst of its own accord, or was opened by the lancet, an operation seldom performed and discountenanced by many surgeons.

However, it seems that the above routine treatment may be replaced by another, much more active and, above all, much more satisfactory to the suffering patient. According to Dr. Durand, of Lyon, dried beer yeast, which has given such good results in furunculosis, erysipelas, chronic bronchitis, pneumonia, &c., has an almost immediate effect on phlegmonous tonsillitis. He cited the case of a young girl, *æt.* 22, who each spring-time was seized with tonsillitis, ending always in suppuration. The beer yeast was given on the fourth day of the affection in doses of four teaspoonfuls a day. In a few hours the patient felt great relief and finally got well after having simply expectorated a few drops of sanguineous pus. MM. Toupet and Terry, of Paris, writing on the same subject, said that the employment of yeast suppresses in the space of ten or twelve hours pain in swallowing and at the same time the distressing lancinating pains in the ears disappear. At the end of one or two days of the treatment, the patient is able to continue his occupation, although the tonsil is still large but not painful. The ordinary dose of the yeast is three teaspoonfuls daily.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 17th, 1903.

At the Medical Society, Hr. Lexer discussed the LOCAL TREATMENT OF SURGICAL GENERAL DISEASES.

Although routine treatment must be rejected, its principles might be discussed. There were three typical groups of such diseases that required special treatment.

First there was the group of toxic infections of which snake-bite was the type. Here the object was to prevent absorption as quickly as possible. As the chemical means of destroying the poison frequently failed, it was proper to try and let out the toxins by large incisions in the injured extremity.

The type of the second group was anthrax. In this the danger lay less in the local process than in the metastasis proceeding from it. He noted particularly the experiments of Schimmelbusch and Friedriech with regard to it. The first of these determined that when a mouse was inoculated with the disease in the tail, the general disease could not be prevented even when the tail was amputated a short time later; but the germ must be rubbed in to the wound. Friedriech infected mice on a smooth cut surface of the tail, and fixed them so that the tail hung in bouillon. In this case the general infection did not come on. From this the speaker concluded that all energetic interference was injurious. Treatment should be limited to a protective salve or protective dressing, and, by fixation or suspension, preventing any injury to the damaged limb, then the fever would quickly subside and recovery take place. During the past eleven years he had treated fourteen cases of anthrax in this way, and had only lost one of them from intercurrent non-specific pneumonia.

In most suppurations, excitants of suppuration entered the blood which stimulated the production of antitoxic material. Only when these excitants were very virulent, or the organism non-resistant, did any dangerous growth of the germs take place. The entrance of large quantities of such germs into the blood should therefore be prevented as much as possible. All rough treatment where there was suppuration, such as pressure and squeezing out of boils, should be avoided. The most sparing agent was the knife.

When the abscess was opened, the dry tampon was preferable. This arrested hæmorrhage and soaked up the poison. It acted more energetically than a caustic or carbolic acid scab could, under which the poison might be retained. On taking out the tampon the wound should be syringed out freely with solution of peroxide of hydrogen, as being but little irritating. For the casting off of necrotic sloughs, when the local process had ceased to advance, moist dressings could be used. Wet dressings were only good at the very commencement of an inflammation. When pus was formed, or in process of being formed, they really favoured the process of necrosis, and were therefore to be unconditionally rejected.

In case of offensive processes, such as abscesses near intestine, infiltration of urine, and phlegmonous pus, the speaker did not use iodoform gauze as it decomposed too readily when the iodoform became absorbed.

The third group was one in which there was direct multiplication of germs in the wound, from which the toxins were taken up. To this group belonged tetanus, rabies, and glanders.

In the case of tetanus, part of the excitants could often be removed along with the foreign body with which they had entered. The greatest difficulty in the way of elimination was presented in the case of large flap wounds packed with dirt. Here timely amputation might still save life, as was proved by a case exhibited.

In the case of rabies, the period of incubation was so long that there was more prospect of success from excision of the wound and trimming of the edges.

The contrary of this was the case in glanders, where treatment was generally too late. Here treatment must be limited to simple incision and the wound must not be scraped out.

At the Society für innere Medizin, Hr. Ruhemann reported on

MESOTAN.

a preparation of salicylic acid, of which it contains 71 per cent. If half a teaspoonful were rubbed into the skin, absorption took place in a short time, and salicylic acid could be demonstrated in the urine. By being used on the skin no after-effects, often noted when salicylic acid was used, were seen, so that the whole surface of the body might be dusted over with mesotan without any ill-effects following. He had had as much as 250 grammes rubbed into a patient during a short space of time without any manifestation of after-effects. In cystitis, after the rubbing in of a few teaspoonfuls of mesotan the pus cells disappeared from the urine; in chronic bronchitis the fester quickly disappeared. It was useful in all cases in which salicylic acid was indicated.

At the Hufeland Society, Hr. Mankiewicz showed a

FOREIGN BODY FROM THE URETHRA

of a man. It was a rubber tube, such as are used for inflating the pneumatic rubber tyres of bicycles, and was found eight centimetres behind the external meatus urethræ of a man who complained of frequent desire to micturate. The man asserted that he had passed the tubing in to prevent the outflow of urine. Before the speaker attempted to remove the foreign body instrumentally he told his patient, as he always did, to take a warm bath. Whilst in the bath the patient stated that the tubing was expelled spontaneously. It had no doubt been placed there in the first instance for onanistic purposes.

THE CLUB DOCTORS' STRIKE.

At Gera, in South Germany, this has been approved by the Leipzig Medical Association. It is felt there as in England, that the terms which were established

many years ago are no longer adequate, but the friendly societies decline to recognise the claim. To render the blockade rigorous, the medical men on strike refuse to attend the members of the recalcitrant societies even as private patients, a step which public opinion is not likely to approve.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 17th, 1903.

CHOLELITHIASIS.

At the Gesellschaft der Aerzte Ullmann showed a patient, a female, æt. 57, on whom he had operated for calculi in the choledochus by the combined method. He commenced by performing cystotomy and attaching the gall-bladder to the wall of the abdomen by a few stitches. On the fifth day he began to inject into the fistula sesama oil, which is less liable to decompose than almond oil. On the ninth day he endeavoured to pass a sound into the cystic duct, wherein lay a calculus which had now become movable and was easily extracted with a pair of forceps.

He related a similar result in another case where the stone was wedged firmly in the ductus choledochus.

Eiselsberg criticised the operation as one of great difficulty, and preferred to perform both choledochotomy and cysticotomy.

ALPINE AND MARINE TREATMENT.

Konrad observed that climates were roughly divided by therapeutists into "dry-cold," "moist-warm," or "dry-warm" and "moist-cold." The two latter, he thought, might be disposed of at once as their therapeutical action was injurious, or, at any rate, non-remedial. In the Alpine ranges of inland seas both of the former are met with. The "dry-warm" atmosphere is usually found in deserts such as the north of Africa; the "dry-cold," which acts as an excitant; while the "moist-warm," or insular climate, acts as a sedative agent. Under the influence of great altitudes the red blood corpuscles are increased as well as the hæmoglobin. There is also a greater intake of oxygen and elimination of carbonic acid. These inland sea regions lie for the greater part between 0° and 5° of the winter isotherm, or extending probably to the tenth isotherm, which occurs in the Tyrrhenian and Adriatic, extending over the South of Italy, Sicily, and Corfu. In the north of Italy there is a cold region in the plain of Lombardy, while in the Lake district it is more temperate. The shores of Dalmatia have a colder summer climate and a warmer winter one than the opposite Italian shores, south of France, or the Riviera. There are elevated sanatoria in central Alpine districts such as Arosa, Davos and Engadine which are beneficial to phthisical patients, as well as many others suffering from abdominal complaints. On the other hand patients suffering from laryngeal tuberculosis profit most by a moist-warm climate. The Engadine is not as suitable in the winter as the summer, owing to a constant wind that prevails there, while Arosa and Davos make excellent winter resorts, having no air currents.

The Southern Tyrol is especially suited for the same reason, having a very mild climate and little wind, particularly at Vitrolio. Gleichenberg, in the same neighbourhood, has a moist-warm climate. The Riviera may be represented as very similar in this respect, as it has a dry warm land breeze, succeeded by a moist warm sea breeze.

Lussin has a moderate temperature resembling that Rome, Corsica, and that of Corfu. The desert climate

of Northern Africa is indicated in cases of arthritis, nephritis and rheumatism.

INFANTILE DISEASES.

At the *Doktoren-Kollegium Weiss* discussed the whole subject of infantile diseases as met with in private practice and hospitals. The death-rate of infants during the first year ranged throughout Europe between 97 per 1,000 in Ireland, to 296 in Russia, while Austria is not so far behind with 254 per 1,000. The causes of this high death-rate may be divided into physical and social. Under the former may be classed the health of the parents, high birth-rate, and other predispositions to disease common in infants, particularly those affecting the alimentary tract. According to the statistics collected in Vienna between the years 1867-88 the deaths of infants are recorded as 190 per 1,000 dying from asthenia; 290 from diseases in the alimentary tract; 40 from tuberculosis; and 73 from infectious diseases.

To the second or social category may be attributed poverty, bad surroundings, and over-crowding. According to the latest statistics of the *Fürstenhäuser* 78 per 1,000 of the children who died were of very poor parents. Among such as clerks, 177 per 1,000; in artisans, 207; labourers, 300; while among those receiving parish relief 363 per 1,000. In one township of Vienna the death-rate is 93 per 1,000, while in the "X Bezirk" it is 299 per 1,000. Another factor in the death-rate is the climate.

In summer the death-rate is twenty-one times greater than at any other season. The greatest enemy, however, is artificial feeding. According to the figures of the Munich Corporation we find that June, 1902, has a death-rate of 70 per 1,000 of breast-fed infants and 930 per 1,000 among the bottle-fed. We in Vienna seem to be in a better position, having an average of 77 per 1,000. This happy result is due, probably, to the large number of orphanages, and the example is being followed in Berlin, Strasburg, &c., with very beneficial results.

There is little doubt that rational artificial feeding can be made to yield as favourable results as breast-feeding. In many of these institutions wet-nurses have been engaged for weaklings, and then six or eight weeks will suffice to remedy the malnutrition and restore the infant to a healthy condition.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

EXTENSIVE OPERATION FOR RECURRENT CARCINOMA OF TONGUE, FLOOR OF THE MOUTH AND LOWER JAW.—Mr. MAYO COLLIER operated on a woman, *æt.* 53, the subject of carcinoma of the tongue, floor of the mouth and lower jaw, on whom three previous operations had been performed for the same affection. Mr. Collier said the present condition of this patient was apparently hopeless. The disease originally appeared as a nodule inside the left cheek near the opening of Stenson's duct. This had been freely removed by one of Mr. Collier's colleagues, but within six months had returned and had invaded the lower jaw. This also had been removed, and with the growth part of the lower jaw, but within three months the old scar became involved and secondary glands appeared below the jaw. These were freely attacked and removed in September last. At the present time a large mass protruded from under the tongue on each side of the *frænum*. This mass invaded the floor of the mouth, and had already extended to the lower jaw in the mid-line. Mr. Collier said in this case the surgeon was on the horns of a dilemma, and whatever course was adopted, an un-

satisfactory result was almost certain. If no operation were performed then death was certain within three months, with all its attendant horrors. If an operation was decided upon then nothing short of the most extensive removal of tissues, with its accompanying disfigurement, discomfort and misery, was likely to be of the smallest avail. The disease was apparently of such a virulent type that, to ensure a measure of success or few months' respite, the whole tongue, floor of the mouth and a greater part of the lower jaw should come away. These points being explained to the patient, an operation was decided upon. The lower lip was divided in the mid-line and separated from the bone for some distance on either side. The lower jaw was sawn through in the bicuspid region on each side and removed. The tongue was next drawn forward and, with the entire floor of the mouth, and growth, was removed with curved scissors. The arteries were easily secured. The parts were adjusted and the stump of the tongue secured with a stout silk thread. The patient was sent to bed with instructions to the attendants to keep the face down so as to encourage natural drainage. Mr. Collier pointed out that this operation, although of an extremely formidable nature, can be performed rapidly and safely without tamponing the larynx and without previous ligature of the lingual arteries. If the tongue be forcibly drawn forwards the parts are almost bloodless during the excision, and the arteries can be easily secured with scarcely any loss of blood by a smart assistant.

"DREADNOUGHT" SEAMEN'S HOSPITAL, GREENWICH.

CASE OF OPERATION FOR DUPUYTREN'S CONTRACTION OF THE PALMAR FASCIA.—REMOVAL OF THE PALMAR FASCIA.—Mr. WILLIAM TURNER operated upon a man, *æt.* 38, a sailor, who was suffering from Dupuytren's contraction of the palmar fascia of the left hand, affecting the ring and little finger particularly, and the middle finger to a less degree. The hand was thoroughly purified the morning of the operation and again when the patient was under the anæsthetic with soap and water, turpentine, ether, and 1 to 20 carbolic acid lotion, particular care being taken of the clefts between the fingers. A longitudinal incision was made through the skin over the band which ran to the ring finger from just in front of the anterior annular ligament as far as the web of the fingers, but so placed as to cover the centre of the metacarpal and first phalanx of the ring finger; practically no hæmorrhage occurred at this stage. Then the skin on the outer side was carefully dissected off the adherent palmar fascia beneath, a very tight band of which ran to the ring finger, so thickened as to simulate very closely a small round tendon. This was then easily separated from the structures beneath by extending the finger and divided posteriorly close to the annular ligament and in front, where it was attached to the flexor sheath and sides of the first phalanx. Then a little more separation of the skin enabled the band passing to the middle finger to be similarly dealt with, but here some hæmorrhage occurred from some of the superficial twigs of the palmar vessels, but it was easily controlled by pressure. The inner portion of skin was separated as before, and the portion of fascia going to and affecting the little finger completely removed. The skin was then brought together by interrupted fine silkworm-gut sutures; no vessels had to be ligatured, and the wound was dressed with double cyanide gauze and wool in the usual manner, a splint being placed on the palmar surface to keep the fingers extended for the first few days. Mr. Turner said there was apparently no causation to be discovered for the condition in this

patient. In most cases that he had seen one of three causes had been traced, namely, hard work with the fingers flexed and pressure in the palm, as using a spade all day; or a definite gouty or rheumatic diathesis, when the trouble is usually bilateral and commences in a rheumatic nodule of fibrous tissue in the palmar fascia and gradually spreads along; or, lastly, it may be associated with a congenital tendency, in many cases descending in a family from father to son. This case was, therefore interesting as no cause could be assigned for the condition and the right hand was unaffected, although the man was right-handed in his work, and there was no sign of any definite nodule. He went on to say that he preferred the operation as above performed to the other methods which have been described, namely, subcutaneous division or Kocher's Y-shaped incision, as in both of these the fascia is not removed and the causation of the fibroid thickening and contraction of the same still, acting recurrence is the rule and not the exception. He then went on to state that there were two main difficulties in the operation, first, the purification of the skin, as the epithelial layer gets so thickened and horny, and consequently it is difficult to make the carbolic acid penetrate deeply, again from the attachment of the skin to the fibrous tissue little pits are often seen which collect dirt very readily; and secondly, the separation of the skin from the palmar fascia without injuring or perforating the former or cutting off its blood supply so completely that portions slough and lead to much scarring in place of linear cicatrix. If this occurs it is wiser to skin-graft as early as possible so as to avoid leaving scar tissue in place of the palmar fascia. The wound was stitched up with interrupted sutures and not a continuous one, so as to more easily allow for one or more stitches to be removed in case the necessity should so arise from parts of the flaps being under tension and not retaining their blood supply, or from the unfortunate introduction of sepsis into the wound.

Mr. Turner added that he had not found any alteration in the functions of the hand after the operation, the tendons working quite naturally and well beneath the skin.

MESSRS. LEWIS AND BURROUGHS, the well-known firm of dispensing chemists, have had to pay heavily for an error in transcribing the directions for taking certain calomel pills. Instead of "two pills to be taken at bedtime," they sent twenty-four, two of them being directed to be taken three times a day. The result was that the unfortunate patient developed mercurial poisoning and was awarded by a sympathetic jury the sum of £150 by way of damages. The only defence possible was that the prescription was rather illegible, but the jury evidently thought that chemists are expected either to read prescriptions aright or else to "refer to drawer."

A ROUMANIAN medical man, Dr. Vasile Georgeson, is at present tramping through England in accomplishment of a wager entered into by him to traverse every country in Europe within thirty months, but he has still 11,000 miles to accomplish, and is not over-sanguine of fulfilling his task within the appointed time. He will arrive in London in due course, but will probably receive a less popular reception than that accorded to his *confrère* from Vienna.

WE note that *Truth*, the editor of which is by no means hand in glove with the medical profession, shares our views as to the injustice of the supersession of the ordinary practitioner by the pathologist patronised so extensively by Mr. Troutbeck, the Coroner for Westminster. Our contemporary agrees that Mr. Troutbeck must be labouring under some misapprehension as to the circumstances under which it is desirable to call in the services of a specialist.

"SALUS POPULI SUPREMA LEX,"

WEDNESDAY, JANUARY 21, 1903.

A FRESH DEPARTURE IN BRITISH MEDICAL ETHICS.

DURING the past week a startling event has disturbed the usual relations of the medical profession of the United Kingdom with the outside public. Briefly stated, a foreign surgeon has demonstrated to a number of English medical men in a London special hospital a particular method of surgery, the details whereof have been fully and minutely reported in the daily newspapers. The operator was Professor Lorenz, and his particular method was a "bloodless" one of operating on congenital dislocations of the hip and other malformed joints by forcible rupture of muscles and manipulation of the bone or bones into position. The method is not altogether new, indeed, the professor has been actually described by one journalist as the "lineal successor of the celebrated bone-setter, Hutton." Professor Lorenz, as most of our readers will remember, has recently visited America, where he performed his "bloodless" operation upon the daughter of an American millionaire. The fee paid him for his services on that occasion was measured on a princely scale, and that fact, together with a precise account of the professor's movements, have formed the subject of frequent foreign telegrams throughout Europe for several months past. According to their wont the Americans made him the hero of the day and showered upon him receptions, banquets, and distinctions of all kinds, including the crowning honour of a doctorship of laws of Chicago. The whole visit, in short, through no fault of the professor's, resembled rather the tour of some showman than the professional visit of a distinguished Continental surgeon to an American patient. Here on this side of the Atlantic the medical profession was content to read the telegrams announcing the professor's progress with a shrug of amusement and a sincere

self-congratulation that our ways were not as foreign journalistic ways. The latter view, however, can no longer be maintained in its entirety, for the visit of Professor Lorenz to London on his way back to Austria has been signalised by a chorus of journalistic notice of pure Transatlantic type. Thus, in various London newspapers of the 15th instant, under the heading "Bloodless Surgery," appeared accounts of half a column in length describing the demonstration of operative methods given on the previous day by Dr. Lorenz at the City Orthopædic Hospital. Seventy medical men were reported to have been present, among them Sir Alfred Cooper and Mr. Alfred Fripp, who have our sincere sympathy at this unforeseen public notice of what to them was doubtless a simple professional visit. Mr. E. Noble Smith, senior surgeon to the hospital, received the professor, and was assisted by the other members of the staff, Mr. John Poland, Mr. Chisholm Williams, and Mr. J. Jackson Clarke. Their names were given in full, with the additional information that they were all Fellows of the Royal College of Surgeons. Mr. Noble Smith discussed shortly the advantages and disadvantages of the procedure to be brought under notice. Professor Lorenz then made a speech, in the course of which he stated that he had performed two hundred and sixty operations with the knife, "with excellent results in all but four cases," and had practised his present operation in upwards of one thousand cases "with great success in every instance." The manipulations that followed were described in minute detail. The age of the patients, the length of time they were under chloroform, the nature of the disease and of the surgical treatment were given in detail that would have been seemly only in the clinical columns of a medical journal. Thus, one patient, a girl of seven, with congenital dislocation of the hip, underwent a forcible manipulation which ruptured the adjacent muscles, and the head of the bone was finally heard to "jump into its socket." The after-dressing in a plaster case, the after-pain, everything, was minutely described. There is no need to enter into the remaining cases. The chief thing that will interest the medical profession of this country is to learn how reporters were allowed to invade the sanctity of a surgical operating theatre. The whole affair is contrary to all the unwritten laws of the medical profession in the United Kingdom. If this kind of thing be permitted in one hospital, where is it to stop? American professional methods have, happily, not made much progress so far among our countrymen, and it is to be hoped that the carelessness which has permitted the present outrage upon professional dignity and decency to be perpetrated will be traced to its proper source.

THE IMPERIAL VACCINATION LEAGUE DEPUTATION.

THE deputation from the Imperial Vaccination League, which was received by the President of the Local Government Board last week, may be congratulated on having cleared the decks for action.

The deputation was influential and representative, although the President, the Duke of Northumberland, was unable to be present. One point to which attention was drawn, and it is one which, it may be hoped, will appeal to the public at large, is the enormous expense which epidemics, such as prevailed last year and are still rampant in the provinces, entail on the community, the cost of which runs into millions of pounds. This represents the pecuniary consequences to the nation of the anti-vaccination propaganda, but after all, the waste of money is trivial compared with the suffering and sacrifice of life which the spread of the disease among the unvaccinated or imperfectly protected entails. Three great questions will have to be decided in view of future legislation: first, the means of securing the uniform and efficient vaccination of the young; secondly, re-vaccination at the termination of school life; and, thirdly, by what authority the vaccination laws would best be enforced. It is generally agreed that the carrying out of the law cannot safely be left in the hands of boards of guardians. As a matter of fact, these bodies, which are largely recruited from the small shopkeeper class of the population, unfitted by education to grasp the bearing and importance of the law which they have hitherto been called upon to administer and subject to every little gust of popular passion and prejudice, have shown themselves in this respect untrustworthy depositories of authority. Incidentally, the question of a more adequate supply of Government lymph was mooted, but this, though an important detail, is not likely to give rise to any difference of opinion. As might be anticipated, Mr. Long, though obviously unable to commit himself to any definite statement in respect of the intentions of the Government, gave unmistakable evidence of sympathy with the object of the deputation. They had, he said, at the Local Government Board, a constant and growing experience of the advantages of vaccination, and the only wonder they felt was that it should be necessary at this period of the world's history for them to come to support that which they in the office, at all events, believed ought to receive the support of every intelligent person. He added that the more he studied the question the more difficult he found it to understand how anyone could fail to give a hearty support to one of the greatest instruments of preventive medicine in the world. Admitting that isolation was in itself an excellent thing he pointed out how impossible it was that isolation alone could have brought about such a remarkable change as had occurred since small-pox was a common disease. Last, but not least, Mr. Long gave a useful hint when he suggested that if the facts were only made known and the evidence placed before the people they would have a much larger majority even than they had at present in favour of vaccination. These assurances will materially assist the League in the task to which they have set their hands, and it behoves every member of the profession to do what in him lies to bring before the public the

facts and figures upon which the protective effect of vaccination is based.

SYPHILIS AND LIFE ASSURANCE.

THE influence of syphilis on mortality is a subject of pressing importance to all engaged in assurance work. Unfortunately, wide difference of opinion exists, and there is a conspicuous lack of uniformity in practice. The matter has of late attracted considerable attention, and it is to be hoped that as a result of the discussions which have recently taken place clearer indications for judicious selection will be rendered apparent. Dr. Byrom Bramwell, in the last issue of his very attractive *Clinical Studies*, deals with the relationship of syphilis to life assurance with well-ordered care. He shows that while Mr. Jonathan Hutchinson considers that the fact that a man has had syphilis ought not to weigh for anything at all in reference to assurance, and that for such purposes it may actually have been an advantage for a man to have had syphilis, on the other hand there are others who would not accept anyone who has had syphilis as a first-class life. The majority of medical advisers at the present time, however, generally accept at ordinary rates a proposer who has suffered from primary and secondary syphilis, in which adequate mercurial treatment has been carried out, and in which a sufficient time has elapsed since the onset of the disease and since the secondary symptoms have disappeared. Dr. Greene, whose recent work on "Examination for Life Insurance" is deserving of careful study, states, speaking mainly from American experience, that: "Most companies will insure syphilitics at ordinary rates if treatment has been efficient, and a period of not less than five years has elapsed since the disappearance of all symptoms. The author firmly believes this to be an error, and would, under no circumstances, advise that a straight-life policy be issued to a man who has a syphilitic history." Dr. Bramwell believes that syphilis very definitely tends to shorten life, and he advises assurance companies to protect themselves by imposing an extra rate on every case in which there is a history of syphilis. Dr. Graham Brown, in the current number of the *Scottish Med. and Surg. Journ.*, expresses a somewhat similar opinion, declaring that "a man infected with syphilis has not a normal longevity, and should not be insured at normal rates." The question is one of great importance. Syphilis is still unfortunately a very common form of infective disease. Life assurance has now become a customary procedure with almost every thoughtful and judicious citizen. Hence not only in the interests of the assurance offices, but in common honesty to their clients, it is most desirable that this matter should not be left to the haphazard of directors or the prejudice of examiners, but should be controlled by some uniform procedure which should be based on extensive and well-investigated medical experience.

Notes on Current Topics.

A Pioneer Physiologist.

THE remarkable case of Alexis St. Martin, and the important advance in our knowledge of the physiology of the stomach which followed from it have been again brought back to the medical mind by an address delivered by Professor Osler some little time ago before the St. Louis Medical Society. Professor Osler took as the subject of his address the life of St. Martin's preserver and patron, "Dr. William Beaumont, a Pioneer American Physiologist." The story of St. Martin may be unknown to many. He was wounded in the stomach at a distance of two or three feet by a shot-gun on the morning of June 6th, 1822, outside a fort on the island of Michilimacinae. Beaumont, who was stationed there in the position of army surgeon, was the first to attend to him. Besides extensive laceration of the walls of the thorax, there was also a direct perforation into the stomach, through which food escaped. At first sight, the case appeared hopeless, but, doubtless owing to the wonderful vitality of the young Frenchman, he survived, and the wound gradually healed with the exception of a fistulous opening into the stomach. The American Government, with a tender-hearted regard for economy, then decided that he was a pauper and useless to them. They accordingly decided to transport him to his place of nativity, and would have done so, at the cost probably of his life, but that Beaumont intervened and took him into his own house and looked after him for two years at his own expense. In 1825, Beaumont began his subsequently well-known experiments, which he continued at intervals up to 1833. During this period the exigencies of military service took him to various parts of America, and in most instances he was accompanied by St. Martin, who in an interval of respite had temporarily returned to Canada and married. In 1856, St. Martin came under the observation of Dr. Francis Gurney Smith, of Philadelphia, for a little time, and finally died at Quebec in his eighty-third year; but, although Professor Osler himself endeavoured to obtain an autopsy, "the man with a lid on his stomach" was buried without such an examination having been made. The results of Dr. William Beaumont's experiments were published in 1833 as a work entitled "Experiments and Observations on the Gastric Juice and the Physiology of Digestion," and a second edition appeared in 1847. Their value—as was pointed out by Combe, who issued an edition in Scotland—was greatly enhanced by the candid and truth-seeking spirit in which all his inquiries were conducted, and in his freedom from the trammels of prejudice or theory. Moreover, their appearance at a time when "some physiologists will have it that the stomach is a mill, others that it is a fermenting vat, others, again, that it is a stew-pan," enormously increased its importance. Beaumont's accurate and complete description of gastric juice still finds its place in many text-books. He con-

firmed the observation of another investigator that hydrochloric acid was the important acid present. He recognised that the essential elements of the gastric juice and the mucus with which it was mixed were separate secretions. He established the profound influence of mental disturbance on the secretion of the gastric juice. He established a number of minor points notably the rapid disappearance of water from the stomach through the pylorus, the motions of the stomach, and the digestibility of different articles of diet. All the time he speaks of himself as "a humble inquirer after truth and a simple experimenter," and yet, as Professor Osler points out, he anticipated many of the most recent advances which have been made in the knowledge of the physiology of the stomach, Professor Osler has enriched medical literature by the address to which we have referred, and has proved himself a most interesting biographer. To those who are desirous of increasing their knowledge of the pioneer worker in the field of stomach physiology we commend the perusal of the address itself.

Divers' Paralysis.

THE curious paralytic symptoms to which pearl divers appear to be subject are well described in a very interesting communication published in a recent number of the *St. Mary's Hospital Gazette* by Dr. Graham Blick, the Government medical officer for Broome, in North-West Australia. The affection presents many points of resemblance with "caisson disease," and no doubt has the same physical origin. No symptoms are experienced while at work, it is only on coming to the surface that the victim develops sudden loss of consciousness with more or less widely diffused paralysis. These cases, in spite of the startling gravity of the symptoms, do not invariably prove fatal, though when recovery does take place, it is extremely protracted. In one case recorded by the author there was paralysis below the level of the neck, even deglutition being difficult, and there is almost always incontinence of urine and fæces. Sensation is in most cases extensively affected. In all the autopsies hæmorrhage into the fourth ventricle was discovered and occasionally slight vascular ruptures in the brain substance. Dr. Blick suggests that bleeding might minimise the lesion, but in practice no treatment at all is adopted, the pearl divers working several days' journey from medical assistance. No explanation has been suggested of the occurrence of hæmorrhage into the fourth ventricle, but the lesions are no doubt occasioned by the sudden liberation, under reduced atmospheric pressure, of the surplus gases which have accumulated in the blood, giving rise to gaseous embolism, and by enhancing the intravascular pressure to rupture of vessels. Contributions of this kind from former students add materially to the interest and value of hospital journals and reports and it would be well if the example were more uniformly followed in view of the special opportunities for original observation which many of them must obtain.

Hospital Clocks.

PUNCTUALITY is a virtue which hospital authorities cannot afford to lack. Not a few hospitals in different parts of the country render the general public a valued service by a well-placed and readily discernible clock. But some institutions for the sick seem more regardful of the man in the street than of their patients, prisoners of suffering, in the matter of time registers. The *striking* clock may become an instrument of exquisite torture, especially during the slow-moving hours of night. From a correspondence in a provincial paper it would seem that the suffering inmates of a large public hospital for years endured the penance of an hourly infliction from the crash and bang of a three-ton clock bell. The clients of hotels in the neighbourhood complained, and fortunately for the interests of the patients, at last secured an abatement of the nuisance. We certainly are of opinion that a noisy bell can hardly be considered a desirable soporific for hospital patients, and certainly, wherever a hospital may be placed, the interests of the sick poor should receive first consideration.

A Medical Colony.

ONE of the most interesting features of London life is the remarkable way in which various nationalities, trades, and professions tend to concentrate in definite colonies. There are many explanations for such, but undoubtedly the chief factor is convenience. And medicine can claim no exception. Harley Street is known throughout the civilised world as the hub of British medicine, the premier residential quarter of those who practise the healing art in England's metropolis. Mr. E. Muirhead Little has recently made inquiry as to the growth of this concentration camp. In 1862, according to the "London Medical Directory," there were 22 practitioners in Harley Street, and 4 in what was then Upper Harley Street. As early as 1850 there were 14 doctors in the local list. By 1855 these had increased to 19, and thence onward the colony flourished; 30 in 1865, 51 in 1875, 68 in 1885, and 125 in 1895. And now, in the beginning of 1903, there are no less than 186 practitioners who claim Harley Street as their address, although, as Mr. Little quaintly puts it, "a few of them must be sought well round the corners of cross streets."

Enteric in South Africa.

DR. P. MURISON, addressing the Durban Town Council last month, said enteric and dysentery were the two greatest scourges in Natal, and in 1901 formed 96 per cent. of deaths. A person suffering from enteric ought to come under the Contagious Diseases Act; he was a danger to the community and a manufacturer of typhoid infection. Fifty per cent. of the cases nursed at home either had their soiled linen washed there or sent to a public laundry. If at home there was often no sewerage, and the waste water was thrown over the back-yard, or allowed to run into the street. He urged the erection of a Thresh's Steam Disinfecter in or near the Fever Hospital grounds, and

the supply of a special soil-pan to unsewered houses containing enteric cases, these pans and the soiled linen to be taken away periodically by authorised persons from the Board of Health. By disinfecting pans and linen as far as possible the chances of spreading infection would be diminished. The grave fact that annual deaths from diarrhoea diseases had for the past three years exceeded one death in every three made the notification and inspection of such cases an urgent necessity.

The Micro-Organism of Hydrophobia.

PROFESSOR SORMANI, of Pavia, in a communication read before the Medical Institute of Lombardy a few days since, described an organism which he believes to be the specific organism of hydrophobia. He describes it as belonging to the group of polymorphous microbes occurring sometimes in the form of micrococci, at others in that of bacilli, and more rarely as blastomycetes, and he designates it provisionally *coccus babyllus polymorphus lissa*. His cultures were obtained from the nervous substance and salivary glands of infected animals, and the organism is stated to grow readily in milk, on potatoes and other media commonly employed in bacteriological research. Obviously the discovery, if duly authenticated, is one of far-reaching importance, this particular organism having hitherto eluded the efforts of investigators to isolate it. Until we are in possession of the technical data upon which the alleged discovery is based it is obviously impossible to offer an opinion as to the validity of the claim, but as the details will shortly be public property, it will not be long before we shall know what importance to attach to the results of Professor Sormani's researches.

The Phonograph in Dentistry.

MUSIC and tooth-drawing—an association first formed by a Paris dentist—is gaining favour in America, where doubtless wonderful and startling improvements on the idea will be made. The Parisian noticed that patients awaking after an anæsthetic showed very unfavourable symptoms, their condition being largely due to the noise of traffic outside. Now, when a patient is seated in the chair he adjusts the phonograph tubes to his ears and the instrument sets to work. Then the anæsthetic is given and he finds unconsciousness comes on quicker and easier, while less anæsthetic is required. The patients, we are assured, awake without headache or discomfort of any kind. A phonograph playing cheerful and inspiring airs will doubtless soon be found in every doctor's ante-room to raise the spirits of anxious patients.

Pure Food.

ACCORDING to the Bill just passed, the American Secretary of Agriculture will have as duty in that country to fix standards of food products and determine the wholesomeness or unwholesomeness of preservatives and other ingredients. One man's food is no longer to be another man's poison. It must be food or poison for all men, as the Secretary

of Agriculture shall determine. The editor of a Chicago paper, who doubtless has interests in some patent sauce or food, asks bitterly: "Where will all such legislation end? And for this particular measure, in view of the fact that the Senate does not seem to greet it with enthusiasm, it may end just where it is, and if it should, the mourning over its demise will not be wide-spread."

The Opium Traffic.

CONSISTENCY is not a distinguishing feature of nations, even when they profess to frame their codes of morality upon the high ideals of Christianity. Thus, the British nation, in dealing with other communities rarely imposes any restrictions upon gunpowder, spirits, opium or other articles the sale of which may be fraught with untold disaster to the civilised or uncivilised people who are the purchasers. In the case of opium the terrible results of the traffic have long been known, but no step has ever been taken by the British Government to prevent the importation into China of that drug by British merchants against the wishes of the Chinese themselves. The late Archbishop Temple studied the question of the Anglo-Indian opium trade with an unbiassed mind. He concluded that such a traffic, carried on by the Government itself, was unworthy of a nation professing the Christian faith, an opinion which must surely be supported by all consistent Christians. The British Legislature has recently passed a law of a most stringent nature restricting the right of their constituent lieges to get drunk. That measure is founded on the assumption that the State is bound to care for the moral well-being of the people. How can a Government of such ideals sanction, or rather actually conduct, an illegal and degrading traffic against the expressed wishes of the Chinese nation?

The Gifts of Patients to Medical Men.

THE relations existing between medical men and their patients are clearly often of a fiduciary nature. In their case, as in that of certain others, the law has asserted a right of control over the extent to which medical men may be entitled to accept gifts at the hands of their patients. It has been established that a medical attendant cannot defend his claim to large sums of money—that is, sums not measurably in proportion to services rendered and to his usual fees—supposing such sums to have been given him informally by a patient. The medical man, however, is entitled to receive a legacy, provided it can be proved that the testator was in possession of proper faculties and was not unduly influenced at the time of making the disposing will. It need hardly be pointed out that a medical man would not have a legal title were he to draw up a will in his own favour at the request of a patient. Under corresponding circumstances a lawyer would be similarly disqualified. A knowledge of these points would now and then save a medical man from being placed in an extremely awkward

position. It would be wise for any member of the profession to decline any large sum of money offered him by a patient. At the same time it would be open for the benefactor to carry out his intention by means of a deed of gift under formal conditions known to every lawyer.

Is Lunacy on the Increase ?

THE vexed question as to whether the increase of insanity in the United Kingdom is real or apparent appears to be answered emphatically in the affirmative, so far as the West Riding of Yorkshire is concerned. That part of the county is particularly well provided with lunatic asylums, but, for all that, further accommodation of the kind will shortly be required. For some years past the undue annual increase of insanity in the county has been the subject of comment. In the year 1902, with a total of 5,061 patients, there has been a total net increase of West Riding chargeable patients of no less than 195. This large total includes neither private and out-county patients, nor 914 insane persons who are housed in the workhouses. In consequence of this influx the local County Council will proceed at once with the erection of the main buildings of the new asylum at Storthes Hall, which it was hoped would not be required for several years to come. The fact that insanity has increased unduly of late years in the West Riding appears to be established. It is to be hoped that the asylum experts in that division of the county, which has often led the way in the scientific investigation of insanity, will be able to offer some satisfactory explanation of this state of affairs. The busy mining and industrial populations of Yorkshire may possibly be showing in this generation a degeneracy resulting from the exposure of their progenitors to long-continued unfavourable conditions.

The Law as to Inquests.

IT is sometimes very difficult to distinguish between deaths due to accident and those due to disease, and some allowance must be made for medical men who unwittingly fail to establish a strict line of demarcation between the two. A case in point occurred last week in London and called down another censure from the Coroner for Westminster on the authorities of St. Thomas's Hospital, this institution being just now in Mr. Troutbeck's bad graces. A lad was admitted who had a sore place on his lip and another on his finger, together with symptoms attributed to rheumatic fever. He ultimately proved to be suffering from pyæmia, to which he succumbed. It was then ascertained that the sore on the mouth was due to a burn caused by a spark from the furnace, and on this ground an inquest was held. A verdict was returned to the effect that death was due to heart failure consequent on blood poisoning, there being nothing to show how the latter had been caused, a verdict which does not throw much light on the point under investigation. It follows that a pin-prick within a year and a

day of death may render an inquest necessary whenever the cause of death does not obviously exclude the possibility of the injury having been the primary cause.

Ritual Circumcision and its Consequences.

AN inquest was held by the Coroner for Westminster a few days since on the body of a child who had died of pyæmia following ritual circumcision. The case was inquired into very carefully, and it appears that in addition to sundry medical operators a certain number of persons are trained to perform the operation with due regard to surgical cleanliness. Dr. Freyberger, who was called in to assist the Coroner, unhesitatingly condemned the way in which the instruments were kept, and the absence of precautions to prevent contamination. A verdict in accordance with the medical evidence was returned. It is obvious that circumcision, when performed by unskilled persons—that is to say, persons not familiar with the practice of surgical cleanliness—presents certain dangers, though it must be admitted that the occurrence of dangerous complications is very rare. It is especially among the poor that the danger exists, since the better-class Jewish parent usually provides for medical superintendence of the operation. Doubtless a lesson of this kind will not be thrown away, in that it will serve to inculcate the necessity for the strict observance of the regulations laid down by the Jewish authorities.

The Spitting Nuisance.

THE Council of the National Association for the Prevention of Consumption have passed a resolution advocating the prohibition of spitting on floors of public buildings, in public carriages, and generally in any covered place of public resort. From a hygienic point of view we are unable to see much difference in the danger between covered places of public resort and others, and from an æsthetic point of view we should very much like to see spitting on footpaths also prohibited. As this is such an altogether new departure, however, we must be thankful for small mercies—when they shall have been accorded by the authorities.

Small-pox in the Provinces.

SMALL-POX continues to spread in the provinces, and fresh cases are daily being notified in Bradford, Nottingham, Leicester, Stockport, Widnes, Newbury, St. Helens, Chesterfield, Derby, Salford, and elsewhere. Although the number of cases in the respective districts is nowhere very large, it is evident that we are confronted with a wide-spread epidemic which it will tax the resources of the local authorities to circumvent. In some instances especially in the smaller towns, accommodation for patients has had to be improvised at short notice, thereby adding greatly to the difficulty of ensuring prompt and efficient isolation. Moreover, isolation is a costly and uncertain process compared with vaccination, and the lesson is one which will perhaps be appreciated elsewhere than in Leicester

Abattoirs v. Slaughter-houses.

THE practical administration of public health in the United Kingdom is, on the whole, possibly the best attainable under existing social conditions. At the same time there is abundant room for improvement in many points. The constitution of local governing bodies, with whom rests the duty of protecting the health of the people, of necessity implies the election of councillors who are interested in various trade interests, the control of which is necessary. In this way we find bakers, publicans, butchers, electricians, and house and land agents often strongly represented on the public bodies in question, to say nothing of other commercial and financial interests. Their presence doubtless serves to protect the trade with which they are associated; but, on the other hand, it often exerts an undue influence in checking the wheels of progress. Instances of that kind of passive obstruction are familiar to everyone who has had much experience of the ways of local governing bodies. There is no more flagrant instance of the harm that can be done than by the retention of slaughter-houses in crowded town localities in the interests of owners who are usually butchers and councillors. In London, as in most of our great towns, the evil of private slaughter-houses is nothing short of a public scandal. Parliament might well insist on the compulsory establishment of public abattoirs within a reasonable number of years. Otherwise the slaughter-houses are likely to linger for many years to the injury of the public and the benefit of the butcher.

St. Bartholomew's Hospital.

THE recent appeal of St. Bartholomew's Hospital for the aid of the Mansion House in its contemplated extension has led to an unexpected storm of hostile criticism. St. Bartholomew's, as everyone knows, is the richest medical charity in the United Kingdom. Roughly speaking, it is built on a site worth about three quarters of a million of money, it is endowed to the extent of several millions, and it enjoys an annual income of £72,000. At the present time only about two-thirds of the available beds of St. Bartholomew's are occupied. In spite of that pertinent fact, however, the honorary treasurer, Sir Trevor Lawrence, is anxious to put in motion the machinery of a Mansion House fund. The plea is that the hospital authorities have bought an acre and a half of the enormously valuable adjacent site of Christ's Hospital at a cost of about £300,000, and want an equal sum of money to build thereon. Hitherto the Mansion House collection has been confined to national purposes, and the proposal to use it for the benefit of a local City charity has naturally attracted a good deal of attention. The policy of going to the public for more money to add to the existing enormous wealth of St. Bartholomew's has been vigorously attacked. The original population around the hospital has decreased, according to some estimates, by 70 per cent. The present vast influx of patients, both out and in,

is to a great extent drawn from the provinces and from northern districts of the Metropolis. With the foundation in the neighbourhood of ample casualty and emergency wards, both out and in, the main hospital would probably be just as available if built in an outlying suburb, where land could be bought at, say, a thousand pounds an acre, instead of a million, the value, roughly speaking, of the present site. A large modern hospital could be erected there with ample and wholesome accommodation for resident staff as well as patients. Teaching could be carried on equally well in a suburb, as students rarely live near a hospital nowadays. As to the convenience of the medical staff, it would be about as easy to go from Harley Street to, say, Hampstead, as to the City. At present we believe that hardly a single member of the senior staff of physicians is engaged in active teaching at the school. The controversy will serve a useful purpose by bringing the question of decentralisation of hospitals before the public.

An Ambulance Service in London.

THE London County Council is awakening to a sense of the scandalous lack of ambulances in the Metropolis, and the subject is at present being investigated by the General Purposes Committee. In most provincial towns the ambulance service is largely worked by the aid of the police, but this plan is impracticable in London, seeing that the police are not under the control of the Council. The other alternative is for the Council to organise an ambulance service of its own, maintained at the expense of the rates, and worked mainly through the agency of the Fire Brigade. This suggestion has much to recommend it, the brigade being well provided with telephones and means of transport, so that we may hope in the near future to see London as well provided with ambulances as some of the large provincial towns.

Building Acts and Fire.

THE fatal fire in the City of London last summer, on which occasion a number of persons were burnt to death on the fifth floor of a warehouse, has not yet been followed by adequate preventive measures. The Metropolitan Fire Brigade, it is true, have done much to improve their apparatus and methods, and at all fires ladders are now available long enough to reach a fifth floor. So far little has been done towards amending the Building Acts, as recommended by the coroner's jury that sat on the fire. The London County Council have decided to urge the necessity of fresh legislation upon Parliament. The City Corporation, however, on the other hand, have shelved similar advice given them by a special sub-committee. Their objection appears to be based on the ground that the carrying out of the alterations required to provide safety exits by roof and otherwise in all existing buildings would entail an enormous cost upon property owners. This evasion of responsibility, if permitted, will leave a vast day population of workers within the City in a state of continual

peril from fire. It is notorious that, owing to faulty construction, a large proportion of the warehouses and other City buildings are simply death-traps in the presence of fire. If the present Building Acts be made retrospective as regards the provision of proper fire exits the cost must clearly fall upon some one, and it seems only fair that the owner of the property should bear the brunt of the expense rather than the heavily rented and heavily rated tenant. The question is one of great importance, not only to Londoners, but to residents in all other parts of the United Kingdom.

The Hygienic Regulation of Barbers' Shops.

THE extremely insanitary, not to say dangerous, manner in which barbers are allowed to conduct their business at present is a subject which would advantageously engage the attention of sanitary authorities. At present, the number of establishments, even of the highest class, in which the necessity for sterilising brushes, scissors, &c., after use is recognised is extremely small, while among the poorer class of barbers such measures are practically unheard of. When we reflect upon the number of diseases—some of them of a severe constitutional type—that can be propagated in this manner, the necessity for reform is very evident. Unfortunately, however, our sanitary authorities as a rule are not remarkable for the spirit of initiative, and are therefore unlikely to agitate for reform of their own accord. It is indeed open to question whether medical journals and medical authorities generally have done their utmost to bring pressure to bear in this direction. We learn from a contemporary that the Canadians are in front of the Mother Country in endeavouring to obtain tonsorial reform. The Ontario Provincial Board of Health have drawn up regulations for the guidance of barbers with the object of ensuring greater cleanliness and of preventing the spread of skin, scalp, and other diseases. These regulations have been brought before the various barbers' associations in the hope that they may be led to adopt them. They are very practical in character, and, with the exception of a direction to boil razors for five minutes after use, are such as would entail but little trouble or expense. We strongly commend them to sanitary authorities who are anxious to justify their own existence by accomplishing a really necessary reform.

Peers' Donations to King Edward's Hospital Fund.

THE acknowledgment by the secretaries of King Edward's Hospital Fund of the receipt at the Bank of England of the sum of £4,094 2s. 4d., "being the first quarterly dividend arising from the securities so generously given to the Fund by Lord Mount Stephen and Lord Strathcona," gives at least a definite idea of the magnitude of the sum which has been given to the Fund by these peers. Securities which yield an annual income of £16,376 13s. 4d., are indeed a munificent gift, and one which well deserved the reference made to it

by the Prince of Wales, who called it the "splendid endowments from Lord Strathcona and Lord Mount Stephen, who have thus extended to King Edward's Fund that open-handed generosity by which they have in Canada created and endowed so many great works of charity." Without in the least wishing to decry the importance of placing London hospitals on the soundest financial basis, we should very much like to see a more universal distribution of the large sum which has been collected for these hospitals of late years. In Ireland, particularly, there are many hospitals which are severely handicapped in their efforts by want of funds. The expenses of hospital management have increased enormously during the last twenty years, both on account of the higher standard of comfort deemed necessary and the introduction of antiseptic and aseptic methods; while at the same time in many instances the receipts of the hospitals in Ireland have diminished in consequence of the depreciation in the value of land. The latter fact prejudicially affects all hospitals indirectly, by depriving them of would-be subscribers, and, worse still, it hits directly many hospitals formerly in receipt of a permanent income from land. No wonder then that the managers of Irish hospitals cast longing eyes at the enormous sums which have been collected of late for London hospitals.

Ocean Travel for the Inebriate.

A SEA voyage is sometimes advised as affording an opportunity for loosing the links of the alcoholic habit. Unfortunately most passenger boats present almost unlimited means for ready access to alcohol, and make isolation from an alcoholic environment practically impossible. Hence medical men now generally recognise that to advise ocean travel for inebriety is worse than useless. We understand, however, that the authorities of a well-known sanatorium for this class of case is about to undertake an interesting experiment. Arrangements are being made whereby the whole passenger accommodation is engaged. A cruise of some eight weeks in the Mediterranean under the personal supervision of a medical man, with complete isolation from alcohol, and constant change of environment, may be expected to afford conditions which should prove of lasting benefit. We shall be glad to learn the result of this praiseworthy experiment.

Ankylostoma in Great Britain.

THE outbreak of ankylostomiasis among the men employed in the Dolcoath mine in Cornwall has been reported upon by Dr. Haldane, F.R.S., and his report has just been published in a Blue Book. The salient feature of the investigation show that the spread of the disease is largely due to carelessness on the part of the men themselves and certain steps are advised with the object of preventing the pollution of mines. Dr. Haldane points out that unless proper precautionary measures are enforced there is no reason why the parasite should not, metaphorically

speaking, gain a footing elsewhere, as well in coal as in metalliferous mines. After this warning it is to be hoped that effectual measures will be taken to stamp out the invader.

The London Hospital Pills.

THE eloquent statistical appeal of the Hon. Sydney Holland on behalf of the London Hospital will, we trust, meet with due recognition at the hands of the charitable public. His figures are startling—92 miles of lint and 476 miles of bandage, plus nine miles of plaster, are serious items; but they pale before 2,500,000 pills and three tons of cough lozenges. There is a proverb that every bullet finds its billet, but we doubt whether as much could safely be affirmed of this arsenal of pills. It is doubtful, indeed, whether the proportion of billets would, on inquiry, be found to rival with the bullets of the French army in 1870, when only one bullet out of six thousand is said to have hurt anyone. The figures, moreover—to those who are cognizant of the lavishness with which medicines and medical appliances are dispensed at our large general hospitals—suggest the possibility and propriety of greater economy in this department. Economically disposed patients have been known to make use of the cod-liver oil for illuminating purposes, and infants in perfect health have been known to partake greedily of the cough lozenges intended for their elders, not always with satisfactory results. Seriously, however, it cannot be denied that a very large proportion of this ocean of medicine runs to waste, and the problem of checking this leakage of much-needed funds is one which might well engage the attention of those who are responsible for the management of our hospitals.

Revivification of the Human Heart.

At the last meeting of the Academie des Sciences a case was reported in which pulsation of the heart in a child of three months of age who had died of double pneumonia, after removal from the body twenty hours after death. An artificial circulation of saline solution containing the mineral elements of the blood, with the addition of a small quantity of dextrose warm and saturated with oxygen, was established, and after twenty minutes weak rhythmic contractions were produced first in the right ventricle, and finally the whole heart resumed regular pulsations which persisted for one hour. The author repeated the experiment on other human hearts, and succeeded several times in provoking pulsations in the auricles thirty hours after death, in spite of the formation of large clots in the organ.

WE are asked to announce that the Annual Dinner of the Gynæcological Society will take place at the Café Monico, Piccadilly Circus, on Thursday, January 29th, at 7 for 7.30 p.m. The president, Sir John Halliday Croom, will occupy the chair. Tickets may be obtained from the hon. secretary (J. H. Swanton, 40, Harley Street, London, W.), price 10s. 6d. each, and ladies may be invited as guests.

The Chelsea Hospital for Women has received from its good friend, "H. M. E.," a further munificent donation of £2,000.

PERSONAL.

DR. S. E. JOHNSON, of Moseley, has been elected an alderman of the City of Birmingham.

MR. JOHN LYNN THOMAS, C.B., F.R.C.S., has been appointed on the commission of the peace for Cardiganshire.

It is proposed to erect a memorial at Munich to the late Professor Pettenkofer, and Dr. Corfield invites the co-operation of sanitarians in this country.

PROFESSOR VON ESMARCH celebrated his eightieth birthday on January 9th, and a memorial to him has been raised in his native place, Tønning, in Schleswig-Holstein.

DR. J. N. LANGLEY, F.R.S., will deliver the presidential address at the annual meeting of the Neurological Society on January 22nd, taking for his theme the "Autonomic Nervous System."

DR. PERCY ATHELSTAN NIGHTINGALE has been authorised to wear the insignia of the Fourth Class of the Royal Siamese Order of the White Elephant, conferred upon him by the Government of Siam for services rendered.

MRS. DEACON, the wife of the Postmaster-General of the Gold Coast, has been appointed Medical Officer of Health to the Colony. Mrs. Deacon was formerly a student at the School of Medicine for Women, London.

THE Lord Chancellor has appointed Mr. Charles S. Bagot to be an honorary Commissioner in Lunacy, in the room of Mr. John D. Cleaton, deceased. The appointment of Mr. F. A. Inderwick, K.C., to be a paid Commissioner in Lunacy, in the room of Mr. C. S. Bagot, is gazetted.

DR. HENRY MOORE, the organising secretary of the most successful bazaar ever held in aid of the Royal City of Dublin Hospital, was presented on Wednesday last with a service of plate in recognition of the importance of the aid which he had rendered to the Hospital. The funds of that institution benefited to the extent of £9,000 by the bazaar, a result which was largely due to the indefatigable manner in which Dr. Moore worked in its interests. Mr. Croly, F.R.C.S., in making the presentation, referred to the fact that this was the second bazaar in aid of the hospital at which Dr. Moore had assisted, and to the extremely satisfactory result of each.

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH UNIVERSITY UNION.—EXTENSION SCHEME.—A public meeting in support of the extension of the University Union was held in the M'Ewan Hall on January 1st. Owing to the indisposition of Mr. A. J. Balfour, the chair was taken by the Lord Rector, who was also the principal speaker on the occasion. Opened some thirteen or fourteen years ago the Union

has probably done more than any other single institution for the comfort and general well-being of the undergraduates, and has promoted good feeling among them by serving as a centre for all kinds of student activity. For several years after its opening the Union was not financially successful—indeed, not until it undertook its own catering was it able to make both ends meet. For a time, too, certain sections of the undergraduates stood aloof from membership, but now the numbers who join are sufficient to over-crowd the building uncomfortably, hence the appeal that funds may be provided to house all who wish to become members of this students' club satisfactorily. The Lord Rector in his speech alluded to the dining accommodation, the library, and the facilities for recreation as being most conspicuously inadequate; to remedy the last-named it is proposed to have two fives courts when the extension is complete. The following resolution, moved by Lord Robertson and seconded by the President of the Union, was carried unanimously:—
 "That this meeting recognising the important position which the Union now holds in the social and academic life of the University, and having had placed before it a statement as to the necessity for its immediate extension, pledges itself to do all in its power to assist in raising the necessary funds." An influential committee was then appointed to co-operate with the Union committee of management in the work of raising the £20,000 which is desired. It is to be hoped that old Edinburgh men in all parts of the world, particularly those who know the advantages which the possession of such an institution as the Union affords to the undergraduates, will come forward liberally and help their successors in the task of enlarging and extending the benefits of the Union.

THE CRUSADE AGAINST TUBERCULOSIS.—PUBLIC MEETING IN GLASGOW.—A public meeting was convened by the Lord Provost of Glasgow on January 14th, to consider the prevention of phthisis and to institute a fund to assist the local branch of the National Association for the Prevention of Consumption in its work. The immediate object of the meeting was to institute a fund for the erection of a sanatorium on a site which the Association has acquired. Mr. Quarrier, whose "homes" are known throughout Scotland, and who has founded sanatoria for the treatment of phthisis, protested against the Association ignoring the work already done, and thought the new Association should be amalgamated with the old one. Dr. Duncan moved, as a rider, that the proposed sanatoria should be for males only, in view of Mr. Quarrier's work at Bridge of Weir for female cases. He said he had at present twenty-three applications by artisans for admission to one of three consumptive beds in which he was interested. It was pointed out that meanwhile the Association proposed only to deal with males, and Dr. Duncan's amendment was accordingly withdrawn.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

AUTOBIOGRAPHY OF THE PRESIDENT, B.M.A.—It is not often that a medical man allows others the opportunity of considering his own view of himself and his doings—save through the columns of the Medical Directory. The distinguished President of the British Medical Association has, however, cast all modesty to the winds, and in the current number of the *Manchester Medical Students' Gazette* indicates the truth of the old saying that "the child is father to the man" by humorously revealing the doings of the "Days of my Youth." We seriously hope that Mr. Walter Whitehead's action in publishing his autobiography, although "writ humorous like," will not become a necessary precedent to be followed by all Presidents of the B.M.A.

MUNIFICENT BEQUEST TO OWENS COLLEGE.—I am in a position to state authoritatively that the late Dr. Schuster, who died last week, has left his valuable laboratory and buildings connected therewith to Owens College.

LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

PROF. LORENZ AT THE ROYAL SOUTHERN HOSPITAL.
 ON January 10th, Professor Lorenz visited the Royal Southern Hospital, Liverpool, for the purpose of demonstrating some of his methods. A large audience of medical men filled the Clinical Theatre. Seventeen cases of congenital dislocation of the hip had been collected by Mr. Robert Jones, together with seven of club-foot and some cases of hip disease with marked deformity. Professor Lorenz first demonstrated his bloodless method of reduction in a case of unilateral dislocation of the hip in a girl, æt. 8. For practical purposes this is the age limit beyond which cases are generally unfavourable. After thoroughly stretching and tearing the tense adductors and extensors, and rendering the parts about the hip "flail," he reduced the dislocation by causing the upper end of the femur to rotate around the lower margin of the acetabulum and enter the socket. By forced manipulation the socket was made more like an ordinary acetabulum, and he was able to demonstrate clearly the slipping in and out of the bone. The thigh was then put up in plaster of Paris by Dr. Müller in the most finished and perfect manner, the position being that of abduction, external rotation and extension at a right angle to the body so as to jamb the head of the bone against the anterior part of the acetabulum. He next proceeded to replace the dislocated heads in a case of double congenital dislocation in a child, æt. 3. This being a suitable age for his method the reduction only took a few minutes, and the patient was fixed in plaster in the same way. A demonstration was next given of his "modelling redressment" of talipes equinus varus, the foot afterwards being placed in plaster. The apparatus which he uses for correcting "short leg" in hip disease was next explained. The audience, which consisted of well-known surgeons from London, Birmingham, Liverpool, Wales, &c., was a most enthusiastic one, and the Professor's demonstration was received with great applause, everyone agreeing that for lucidity and completeness it could not be surpassed.

BELFAST

[FROM OUR OWN CORRESPONDENT.]

EXCESSIVE DISPENSARY EXPENDITURE.

IN connection with the late inquiry into the expenditure on medical and surgical appliances and medicines, some interesting figures were presented to the Board of Guardians last week, giving comparisons between the years 1880, 1890, and 1900. In 1880 there were two visiting medical officers, one resident, and an average of 895 patients weekly, with an average weekly cost per patient for medicines and appliances of 5½d. In 1890 there were two visiting medical officers, two resident, an average of 1,114 patients, and an average cost for medicine, &c., per week of 4½d. In 1900 there were three visiting medical officers, four resident, and an apothecary, an average of 1,468 patients, and an average cost of 10½d. for medicines, &c., per week. It would be interesting to know how these figures compare with those of some large unions in Dublin and the South.

DISPENSARY DOCTORS' FEES—A TEST CASE.

AT the Downpatrick Quarter Sessions on January 16th, before Judge Orr, Dr. MacLaughlin, of Strangford, prosecuted the Guardians of Downpatrick Union to recover a sum of £5 5s., balance of salary alleged to be due to him by the defendants. It appeared that the

um had been deducted by the guardians with the approval of the Local Government Board, being the amount paid by the guardians to Dr. Smyth, who had been employed to act as *locum tenens* when the plaintiff was acting as witness in civil cases at the Down Assizes and Downpatrick Quarter Sessions. The Local Government Board authorised the deduction on the ground that, the cases being private ones, the plaintiff could have arranged for proper fee and expenses before appearing in court. It was contended for the guardians that the Local Government Board had power to authorise the deductions made under Article 24 of the Dispensary Regulations of 1899, and that they were bound by the direction of the Local Government Board.

Upon behalf of Dr. MacLaughlin it was contended that these regulations, on which the defendants relied, gave them no positive power of deduction, nor to the Local Government Board any power to authorise any deduction from a medical officer's salary in a case of this nature. Article 24 was purely negative, restraining the guardians from making any deduction except under certain circumstances, and this article, having been inserted for the protection of the medical officers, was now being used by the guardians as a weapon of destruction.

His Honour considered that upon a general interpretation of the Dispensary Regulations the guardians had the power of deduction given to them in a case in which the medical officer was incapacitated from acting as in this case, and consequently he considered the action must fail, and dismissed the process, expressing the opinion that the case was one which would in all probability go further, and that, although there was some doubt about the case, he would not reserve judgment, but would do all he could to expedite an appeal.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE CONTAGIOUS CHARACTER OF LEPROSY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a reply to the remarks of Mr. Jonathan Hutchinson, in a recent number of the *Polyclinic*, to which you allude in your editorial of December 10th, 1902. I ask for space in your columns in reply thereto.

In the Berlin lepra Conference the non-contagion party of Great Britain and its possessions stood an obstacle to our obtaining the declaration that official delegates should authorise their respective governments to form a permanent international committee against emigration of lepers; that every country which had leprosy colonies should see to it that they were properly isolated, etc. These people claimed that there was no necessity of caring for the 200,000 lepers of India.

As one of the provisional committees of the Berlin Lepra-Conference which promulgated the declaration to the governments of the world that leprosy is contagious, and that isolation of lepers is necessary, let me state further that London, as the place of meeting of that congress, was not selected because Mr. Jonathan Hutchinson had proposed the Prince of Wales as president. Dr. Unna, of Hamburg, thought that this would not do, as his Royal Highness was a pronounced non-contagionist. Moscow, Russia, was defeated because it would give us contagionists too much power, as the Russian leprologists were bitter contagionists. Berlin, therefore, in the interests of the Scandinavian "mixed" isolationists, was chosen.

There is to the isolation of lepers only one great national opponent to-day. That is England. The maintenance of her 200,000 Hindoo lepers, not to speak of her West Indian and other lepers which, as Dr. Beaven Rape, of the Trinidad Leper Asylum, wrote me, are the result of importations of Hindoo lepers to the West Indian British possessions, to work the sugar plantations, would be an enormous

expense. England is opposed to isolation from utilitarian considerations. Recently, as Mr. Hutchinson wrote me, measures for the isolation of lepers in India were withdrawn from Parliament because of the opposition which he led against them. His opposition was certainly not of a scientific, and still less of a philanthropic character.

As for the contagiousness of leprosy, I know of the case of a man who became leprosy by being massaged by Swedish woman whose fingers were diseased. The time of negation is past, and it would be well for him to open his eyes to what is evident. The great Kaposi in 1881 said: "The contagiousness of leprosy, received formerly as a patent truth and then systematically denied, has become again a problem which refuses to be disregarded. What physician," he says in a critical study on this subject (*Gaz. Hebdom.* 1880) "would dare now to inoculate leprosy?"

And you cannot explain the importation of leprosy from one nation to another in the course of the centuries if it is not by contagion. The condition of transmission of which we know nothing; the long incubation of the disease, due, in my opinion, to a prebacillary spore life; the indefinite duration of its latent period, are doubtless so many causes of the obscurity which prevails on this subject. So long as this question is not scientifically answered in the negative, we are of opinion that any measures of general or public precaution are justified, and by such measures alone can leprosy be rooted out or localised.

Founded on facts and modern opinions, the theory of contagion of leprosy is now predominant. Some, for purposes of expediency or other reasons, may not admit it, but they are to-day in a minority. The logical conclusion of all the great leprologists is that the disease is insidiously contagious; that for 100 or 200 years it remains after inoculating a virgin country very slowly endemic, and then suddenly appears in its most hideous form, epidemic leprosy, as in Colombia and South America to-day, and that the people, even the most liberal, are justified in defending themselves by measures of rigour.

Let me state the general laws which govern the invasion of this disease: First, that the leper carries leprosy with him, and that those parts of the world which are now leprosy are so through contact with leprosy individuals. Never have virgin countries produced lepers. The second proposition shows the gradual increase of the disease and the influence of isolation, one being in inverse ratio to the other. The recrudescence of the awful scourge in the whole world to-day constitutes truly an international danger, and every nation must protect itself in the measure of its progress and civilisation.

I am, Sir, yours truly,

ALBERT S. ASHMEAD, M. D.

New York, December 27th, 1902.

DUBLIN UNIV. PARLIAMENTARY ELECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—As an elector of the University of Dublin, as a Poor Law Medical Officer of 25 years' service, and as one who has suffered, in common with many others of my profession, hardships and injustice from those at present in power over us, I am deeply interested in the coming election, and as the result may have far-reaching consequences for Poor Law Medical Men, to whom I principally address myself, I ask them to look on the situation as practical men.

We have two candidates before us—one the Solicitor-General of a Government which, during the passing of the Local Government Act, and since that Act, has had abundant opportunities of improving the condition of the Irish Poor Law Medical Service, and redressing the many grievances of its members, who are men of abilities, men of education, but who are compelled to live on starvation wages—wages which would be refused by an artisan—and then, when worn out in the service, are often left to die in indigence. Thanks to our organisation, and the fact that medical men are

at last beginning to see that unless they look after their own interests no one else will. We are no longer the nonentities we were, we are now a body of men who have to be reckoned with, and Mr. Campbell now suddenly offers, if returned as a Government official, to look after our interests. *Sed timeo Danaos et dona ferentes*. As a law officer of the present Government, I fear his ability to serve us—it must be limited. It will be impossible for him to ask questions, move resolutions, introduce legislation, or discuss amendments, except from the Government point of view.

On the other hand, we have in Mr. Samuels a man who will be independent and unfettered by office, and ready and willing to serve us in every way, *vide* his letter to Dr. Kinkead of 30th October, 1902, published in your Journal of the 7th inst., and other papers. He gave me his promise some months ago, and recently renewed it, that he would do all in his power to bring to notice and try to remedy the scandalous abuses from which Poor-law Medical Officers in this country suffer. I, therefore, appeal to my brethren in the Poor-law Service who have votes, to give them to Mr. Samuels, and to try and induce their College contemporaries, who are living in England under happier circumstances, to think of us, the poor Dispensary Doctors of Ireland, and assist us to return a man who will, I feel confident, do his best to remedy our unfortunate condition.—I am, Sir, yours truly,

F. P. MACLAUGHLIN, M.Ch., Dublin.
Vice-President for Ulster of the
Irish Medical Association.

Strangford, January 16th, 1903.

Literature.

AGE AND OLD AGE. (a)

THIS excellent little handbook will fill a gap in many a medical bookshelf. While there are many books dealing with childhood from every conceivable point of view there are exceedingly few that treat of the opposite extreme of life. Indeed, the author is the only medical writer, if we remember aright, who has approached the subject as a whole for at least fifteen or twenty years. The little monograph by the late Sir George Humphrey, valuable though it be, is confined to old age, pure and simple. The author, on the other hand, is careful to discuss "age" and premature senility as apart from old age. In a simple, attractive style he has treated the subject systematically and with sufficient detail to secure the attention of the reader without losing sight of the main principles. Hence medical practitioners, especially those who are entering upon active practice, will find a variety of useful information between the covers of this little volume. The chapter headed "The young man old before his time" contains a deal of suggestive matter, and the influences of alcohol, dissipation, athletics, occupation, exposure and so on upon the advent of senility, are temperately and reasonably discussed.

The author's classification of his subject is somewhat novel. He improves on the commonly accepted definition of old age as that period of life following maturity in which the degenerative processes become marked. His more extended view describes it as "That condition following maturity in which the bodily and mental powers begin to wane, first gradually (senescence) and then in a more marked way (senility), the former appearing naturally about the 50th to the 60th year, but sometimes occurring prematurely at any period of middle age, while senility may come on at any subsequent period, but usually about the 65th or 70th year." This definition provides for the prematurely aged, the ageing, and the aged man. All the varieties of age and old age are discussed from various points of view, and many instructive and original

observations are made. The whole book from beginning to end is characterised by sound common-sense and clear expression. Dr. Walsh's little volume may be cordially recommended to all who want information as to the decline of life, a period for which preventive medicine is doing more and more.

CREIGHTON ON CANCERS AND TUMOURS. (a)

THE object of Dr. Creighton's book is to prove that glandular structures, having the anatomical character of axillary sweat glands are present in a surprising number of breasts, and that they are "the true seat and anatomical cause of all varieties of mammary tumour, not only of the soft intracystic and intratubular, but also of sarcoma in general, of scirrhus, of colloid, of steatoma or pearly tumour, of fibroma and of simple cysts." He considers that the proper mammary structure always remains passive. In an anatomical introduction the author deals with the comparative anatomy and evolution of the skin glands in different animals. The conclusion is come to that the primitive mammary gland is of the sweat gland type. Several cases are recorded where structures, which Dr. Creighton considers to be sweat glands, were found in the breast, but so far as we have been able to follow the description he considers every tube with muscular fibres in its wall to be of necessity a sweat gland. He expresses the opinion, "both upon antecedent grounds and on the evidence of an original case," that the peculiar cancer of chimney-sweeps and of workers in tar is traceable to a special deposit of sweat glands in the scrotum and groins. In the original case of this disease that he describes he appears to have examined only a small portion at the edge of the excavation. He considers it is sarcoma not epithelioma, and adds "I suspect that this kind of tumour of the cutis in chimney sweeps and the like is always sarcomatous."

A number of tumours in the mammary glands of butchers are described, and the inference is drawn that they originate in connection with sweat glands, and there is a chapter on "Scarcomatous tumours of sweat glands in non-mammary regions of the dog's skin." In this twelve cases are described, but in all the origin of the tumour from sweat glands appears to us to be purely an assumption; thirty-six breast tumours of various sorts in the human being are related in the book, and each is considered, on evidence that we believe to be entirely insufficient, to originate from sweat gland structures. The book is illustrated with numerous lithographs.

LITERARY NOTES.

OUR contemporaries the *Lancet* and *British Medical Journal* have referred to the rapid printing and publishing of Dr. Latham's *King's First Prize Essay* on "The Sanatorium Treatment of Consumption," as forming a "record" in the medical book world. This work of 254 pages, with separate charts, &c., was passed for the press by the author on Monday, a thousand copies were printed on Tuesday, bound in cloth gilt lettered on Wednesday, and delivered by Messrs. Bailliere, Tindall and Cox at the offices of the leading medical journals on Thursday for review. Such a remarkable piece of publishing enterprise, which heretofore would have been considered impossible, deserves a note of recognition as evidence of progress in the production of medical literature.

DR. G. H. R. DABBS, physician, novelist, dramatist, poet and journalist and author of many delightful works for children, has for six years conducted with considerable success a remarkable little journal called *Vectis*, which, although well known and much valued by a privileged few in the Isle of Wight, was deserving of a wider field. We are glad to know that Dr. Dabbs, having now removed to London, proposes to continue

(a) "Age and Old Age: a Handbook and Guide to the Care of the Aged in Health and Disease." By David Walsh, M.D., late Hon. Sec. to the Rontgen Society; Hon. Physician Western Skin Hospital. London: R. A. Everett. Price 2s. 6d.

(a) "Cancers and other Tumours of the Breast: Researches showing their True Seat and Cause." By Charles Creighton, M.D. London: Williams and Norgate.

the publication of *Vectis*, which, however, now takes its proper place among our Metropolitan monthly reviews devoted to literature, social and dramatic matters. The first number of the new series is dainty in appearance and delightful in substance, and we have no hesitation in heartily recommending it to all members of Dr. Dabbs' profession.

IN the recently issued Vol. XXXI. of the new series of the Encyclopædia Britannica there is much that will prove of service to the student of medicine. Particular mention may be made of such articles as those on Pathology, by Professors Hamilton and Woodhead, with shorter articles by various physicians on systemic affections; Pharmacology, by Professor Stockman; Physiology, by Dr. Pembrey; and Plague, by Dr. Shadwell.

Obituary.

ROBERT THOMAS ALEXANDER O'CALLAGHAN F.R.C.S.I.

WE regret to have to announce the comparatively sudden death of Surgeon Lieutenant-Colonel Robert Thomas Alexander O'Callaghan, of the 1st Flintshire Royal Engineers (Volunteers), at his residence in Harley Street, W., on Monday, the 12th inst. Mr. O'Callaghan was educated at Trinity College, Dublin, in which city he formerly held the appointments of resident surgeon of the Meath Hospital and house surgeon at the Children's Hospital. Having removed to London, Mr. O'Callaghan was appointed surgeon to the Chelsea Hospital for Women, and two or three years since, surgeon and gynaecologist to the French Hospital. During the war he volunteered for service with the Royal Army Medical Corps, to which he was attached, with the rank of major, and he proceeded to South Africa as surgeon-in-chief of the Langham Hospital. For his service in the field he was mentioned in despatches, and received the medal with clasps. He was a frequent contributor to our columns on his special subject, and his untimely death at the age of 44, cuts short an active and useful career.

DR. J. O'SHAUGHNESSY, D.L., OF LIMERICK.

WE regret to announce the death of Dr. J. O'Shaughnessy, of Limerick, who was, probably, the oldest medical practitioner in the three kingdoms. Dr. James O'Shaughnessy was born in 1810, at Toomevara, in the county of Tipperary. In 1836 he became a L.H.H., and in the following year he took the M.R.C.S. of London. On his return to Ireland he commenced practice in Limerick, and soon afterwards bought a partnership or interest in the old-established Medical Hall of McMahon and Company. In time he gradually acquired a large number of clients and gained many medical appointments. He throughout life avoided politics, but was well known as a liberal contributor and active friend to the many city charities. He took a deep interest in Poor-law matters, and as a guardian promoted every measure that he considered to be for the benefit of the medical profession and the welfare of the public. His busy life left little time for medical writing, so that his ripe experience was practically lost to all but his circle of professional and personal friends. That his last public appearance, on the 16th of December last, was on behalf of the Society for the Protection of Children tells the character of the man and was a fitting exit for a life spent in good works. He was a J.P. and a D.L. of the city of Limerick.

Died on the Field.

DR. R. H. DAWSON, of Saundby Grove, near Retford (Yorks), was called to see a tramp who had been taken ill on the roadside a few days since, and he was walking thither when he suddenly succumbed to an attack of heart failure. Dr. Dawson was 63 years of age, and was a very popular practitioner.

Medical News.

The British Gynaecological Society.

At the annual meeting, held on Thursday, Jan. 8th, 1903, the election of the following officers and council for the year took place:—Hon. President: R. Barnes, M.D., F.R.C.P. President: Heywood Smith, M.A., M.D., M.R.C.P. Vice-Presidents: E. Stanmore Bishop F.R.C.S., Professor Murdoch Cameron, M.D., John Campbell, M.A., M.D., F.R.C.S., F. W. N. Haultain, M.D., M.R.C.P., Skene Keith, M.B., F.R.C.S., Professor L. Landau, M.D., H. MacNaughton-Jones, M.D., F.R.C.S.I., J. A. Mansell-Moullin, M.A., M.B., M.R.C.P., Christopher Martin, M.B., C.M., F.R.C.S., F. F. Schacht, M.D., B.A., John Shaw, M.D., M.R.C.P., Professor Alfred Smith, M.B., F.R.C.S.I. Treasurer: Wm. Travers, M.D., F.R.C.S. Council: A. H. F. Barbour, M.A., B.Sc., M.D., G. Roe Carter, M.R.C.P.I., Eber Chambers, M.D., M.R.C.S., R. J. Colenso, M.A., M.D., Sir John Halliday Croom, M.D., F.R.S.E., F.R.C.P., F.R.C.S.E., E. T. Davies, M.D., F.R.C.S., T. M. Dolan, M.D., F.R.C.S., Fred Edge, M.D., M.R.C.P., Bedford Fenwick, M.D., M.R.C.P., Clement Godson, M.D., M.R.C.P., Arthur Helme, M.D., M.R.C.P., Robert Hugh Hodgson, M.D., James Jardine, M.B., C.M., Henry Jellett, M.D., F.R.C.S., F. Bowreman Jessett, F.R.C.S., F. W. Kidd, M.D., B.A., Mayo Robson, F.R.C.S., Charles Ryall, F.R.C.S., W. Slimon, M.D., F.F.P.S., Richard T. Smith, M.D., M.R.C.P., W. J. Smyly, M.D., F.R.C.S.I., Herbert Snow, M.D., W. D. Spanton, F.R.C.S., Septimus Sunderland, M.D., M.R.C.P. Editor of the *Journal*: J. J. Macan, M.A., M.D. Hon. Secretaries: J. H. Swanton, M.A., M.D., Sol Jervois Aarons, M.D. Auditors: C. H. Bennett, M.D., F. A. Purcell, M.D. Trustees of the property of the Society: G. Granville Bantock, M.D., R. S. Fancourt Barnes, M.D., F.R.S.E., Clement Godson, M.D., M.R.C.P.

Liverpool Medical Institution.

At the annual meeting held on Thursday, Jan. 8th, the following list of office bearers, members of council, and committees was adopted. Those marked (*) did not hold the same office last year:—President: Rushton Parker. Vice-Presidents: John E. Gemmell, W. Permewan, *Henry Briggs, and *G. W. Steeves. Hon. Treasurer: *T. H. Bickerton. Hon. General Secretary: J. R. Logan. Hon. Secretary to Ordinary Meetings: J. Hill Abram. Hon. Librarian: *F. H. Barendt. Council: Edgar A. Browne, W. Murray Cairns, D. Douglas-Crawford, Ernest Nevins, W. B. Warrington *F. C., Larkin, *W. J. R. Dunn, *Frank T. Paul, *James Pinkerton, *Alex. Fisher, *C. T. Street, and *A. G. Grunbaum. Auditors: *D. Douglas Crawford and *George Westby. Pathological and Microscopical Committee: R. Boyce, R. J. M. Buchanan, D. Douglas-Crawford, *R. J. Ewart, *Ernest Glynn, *A. G. Grunbaum, John Hay, K. W. Monsarrat, C. G. Sherrington, and W. B. Warrington. *Journal* Committee: The Hon. Secretary to Ordinary Meetings, K. W. Monsarrat, F. H. Barendt, F. C. Larkin, G. P. Newbolt, A. M. Paterson, W. Thelwall Thomas, Arthur Wallace, and W. Permewan.

The Society of Medical Phonographers.

THIS Society will hold its next Annual Shorthand Examination early in May, 1903. Two prizes will be offered, each of the value of £3, one for first-year students and one for students of more than one year's standing. The competition will be open to any registered medical student in the United Kingdom who has not taken a first prize at one of the Society's previous examinations. It will be held simultaneously in London, Edinburgh, Dublin, and at any provincial medical centre in the United Kingdom at which a candidate or candidates shall offer themselves. There is no entrance fee for the examination. Intending candidates should send in their names as early as possible to Dr. P. G. Griffith, Bonhams, Farnborough, Hants, who will furnish them in return with a detailed

Prospectus of the examination. The latest date for receiving enquiries will be April 15th, 1903.

A Medical Strike.

THE medical men at St. Annes are waging war with the Fylde Guardians, and as a result, the parish has been without a resident medical officer for two years. The guardians refuse to offer more than £15 per annum, and the doctors are unanimous in refusing the position unless £20 or £25 is offered. Dr. Eason, the medical poor-law officer for Lytham, has so far "been acting without payment for a district to which he has not been appointed," in the words of the Local Government Board report, and the Board have written the guardians that "the matter should without delay be put on a regular footing." At the last meeting of the guardians it was again decided to advertise for a doctor. A conflict between the Local Government Board and the guardians is imminent.

Medicine or Refreshment.

A CURIOUS case has just been decided at the Bristol Quarter Sessions in which a herbalist appealed against a conviction for selling refreshments in a house not licensed for that purpose. The case turned upon the question whether a product known as "sarsaparilla and dandelion stout" was a medicine or a refreshment. The drink was shown to contain small quantities of sugar and yeast, with about 1 per cent. solids. Evidence was given to the effect that the drink had a distinctly disagreeable taste, and that customers made wry faces when drinking it; but on the ground that people went in for it at late hours and often did not finish it owing to the taste, thus showing that it was refreshment and not medicine that they wanted, the Bench held that the case had been made out, and dismissed the appeal.

Pharmaceutical Delinquencies.

SEVERAL chemists in the potteries have recently been prosecuted for selling mercurial ointment deficient in mercury, the defence being that there was a commercial standard for the article in addition to the pharmaceutical standard. The magistrates summarily dismissed this contention, and fined the defendants, remarking that the offence was aggravated by the defendants having usurped the functions of medical practitioners, and having taken advantage of the opportunity to foist a worthless article upon their customers. In London a retail chemist has been fined for selling Gregory's powder compounded with the light carbonate of magnesia.

Society for relief of Widows and Orphans of Medical Men.

A QUARTERLY Court of the Directors of this Society was held on Wednesday last, the President, Mr. Christopher Heath, in the chair. Three new members were elected, the deaths of seven members were reported; among the deaths were two vice-presidents, Mr. Fregart and Mr. Manley Sims; both had been most energetic members and had taken great interest in the Society. Two members had ceased to belong to the Society. Two widows and three orphans made application for assistance, and grants were made—all had been left without any means of subsistence. It was resolved to distribute £1,376 10s. among the fifty-six widows, thirteen orphans, and five receiving special grants from the Copeland Fund. £590 had been given as a present at Christmas to the widows and orphans in receipt of grants. The expenses of the quarter amounted to £74 15s. 6d.

Medical Charges.

An action was tried at the Cardiff County Court last week in which Dr. W. J. Corrigan sued a gentleman for fees, among the items being one of thirty guineas for the medical cure of hydrocele. This item, among others, was resisted as exorbitant, and several medical witnesses, including the President of the Cardiff Medical Society, expressed the view that from £10 to £15 would be the maximum charge for such an operation. The judge commented upon the unpleasantness of having to adjudicate upon such questions, and gave a verdict for £25, the sum paid into Court, in lieu of the

£50 7s. claimed. The case is one on which we forbear to comment, beyond saying that it is regrettable it should have been brought into Court.

FROM THE "TIMES" OF 1803.

WEDNESDAY, JAN. 19.

EXTERMINATION of the SMALL POX.

London, Jan. 10, 1803.

The invaluable Discovery of Dr. JENNER, for the extermination of the SMALL POX, having undergone the most rigorous investigation, and received the sanction of Parliament, a MEETING will be held at the London Tavern, Bishopsgate-street, on Wednesday, the 19th instant, at 12 o'clock, to consider of the best means of carrying the same into effect; when the company of every Gentleman disposed to concur in this laudable Undertaking is earnestly requested. The Chair will be taken by the LORD MAYOR, precisely at one o'clock.

William (Duke of Clarence), Berkeley, Egremont, Darnley, Somerville, G. C. Berkeley, M.P., J. W. Anderson, M.P., William Wilberforce, M.P., Henry Thornton, M.P. Richard Carr Glyn, Ald., George Hibbert, Ald., William Leighton, Ald., John Julius Angerstein, E. G. Bolero, Thomson Bonar, William Bentham, Henry Hoare, John Maitland, William Vaughan, Nathaniel Fenn, Richard Sharpe, Benjamin Travers, Joseph Travers, Timothy Brown, J. H. Tritton, Robert Cowie, John Gurney, Thomas Wilson, Robert Barnewall, Casten Rhode, Jacob Wrench, Samuel Thorpe, John Nichols, Samuel Parker, Ebenezer Jonnston, James Bell, William Bell, Joseph Benwell, Henry Waymouth, Walter Farquhar, M.D., J. C. Lettsom, M.D., Thomas Denman, M.D., Richard Croft, M.D., Thomas Bradley, M.D., Gilbert Blane, M.D., Alexander Crichton, M.D., William Hawes, M.D., William Babington, M.D., Robert Willan, M.D., Richard Powell, M.D., William Lister, M.D., James Hamilton, M.D., James Sims, M.D., Alexander Marcet, M.D., W. P. Dimsdale, M.D., Samuel Pett, M.D., Henry Cline, John Ring, John Abernethy, Astley Cooper, Edward Ford, John Pearson, John Griffiths, C. R. Aikin, John Addington, William Chamberlain, James Simpson, Joseph Fox, Charles Johnson, William Allen, George Johnson, J. Potts, John Christie, Joseph Leaper, John Buxton, Ives Hurry, Thomas Walker, E. L. McMurdo.

Indian Medical Service.

The following is an official list of the Candidates for His Majesty's Indian Medical Service who were successful at the competitive examination held in London on the 13th January, 1903, and following days, arranged in order of merit:—

| | |
|---|------|
| C. S. Parker, M.B.Lond. M.R.C.S., L.R.C.P. | 3413 |
| F. N. White, M.B.Lond. M.R.C.S., L.R.C.P. | 3068 |
| T. C. Rutherford, M.B., B.S.Durham M.R.C.S., L.R.C.P. | 3037 |
| D. Heron, M.B., B.Ch.Edin. | 3018 |
| L. Reynolds, B.Ch.Camb., M.R.C.S., L.R.C.P. | 2987 |
| H. H. Broome, M.B., B.Ch.Fdin. | 2940 |
| C. G. Seymour, M.R.C.S., L.R.C.P. | 2930 |
| E. C. Taylor, M.B., B.Ch.Camb. | 2890 |
| D. P. Goil, M.B., B.Ch.Edin. | 2865 |
| H. C. Keates, M.B., B.S.Lond. | 2860 |
| R. N. Needham, M.B., B.S.Vict. M.R.C.S., L.R.C.P. | 2827 |
| J. Kirkwood, M.B., B.Ch.Edin. | 2812 |
| A. Whitmore, M.B., B.Ch.Camb. | 2782 |

The Unqualified Assistant.

In an inquest held at Stepney last week by Mr. Wynne Baxter, one Zephr, who was stated to be acting as dispenser to Mr. J. J. Harvey, L.S.A., appeared to have paid a professional visit to the deceased child, and according to the Coroner this was not the only occasion on which he had thus intruded. The jury appended a rider to their verdict requesting the Coroner to call the attention of the Medical Defence Union to the facts of the case.

Notices to Correspondents, Short Letters, &c.

✍ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ACCEPTED COMMUNICATIONS.

THE following papers, lectures, and cases have been received and will appear in due course:—

"On the Curative Treatment of Trachoma by X-Ray Exposure and by High Frequency Current." By Sydney Stephenson, M.B., F.R.C.S., and David Walsh M.D.Ed.

"On Tuberculous Peritonitis in Children." By George Carpenter, M.D., Physician to the Evelina Hospital for Sick Children.

"A Case of Leukæmia Associated with Tuberculous Mesenteric Glands." By George Carpenter, M.D.

"The Prognosis of Tuberculous Peritonitis in Children." By G. A. Sutherland, M.D., M.R.C.P.Lond.

"A Case of Scrotal Hernia." By Stanley Barling, M.R.C.S., L.R.C.P., of Lancaster.

"Ocular Headaches." By Sydney Stephenson, M.B., F.R.C.S.

"A Case of Renal Sarcoma, Nephrectomy." By S. J. Ross, M.B., Ch.B., of Bedford.

"Cases from the Dermatological Clinic." By G. Norman Meachen, M.D., M.R.C.P.Lond.

"The Diagnosis of Facial Neuralgia of Dental Origin." By Hy. Sewill, M.R.C.S., L.D.S.

GROUP D.—We insert nothing in our columns that is sent us anonymously.

A LIVERPOOL SURGEON.—We shall be pleased to give you an opinion if the pros and cons of the case are placed fairly before us.

Mr. J. L. S. is thanked for his communication, which is, however, scarcely suitable for our columns.

SIR J. HALLIDAY CROOM'S address is unavoidably held over, corrected proof not having been received until too late for present number.

UNAUTHORISED PUBLICITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention having been called to the undue prominence given to my name in a pamphlet on "Catarrhal Deafness," published by the Akouphone Manufacturing Company of New York, I trust it is hardly necessary for me to state that this has occurred entirely without my knowledge or consent. I have requested the company to discontinue the use of my name.

I am, Sir, yours truly,

DUNDAS GRANT.

18, Cavendish Square, London, W., Jan. 8, 1903.

J. V. R.—We have no reason to believe that any radical change of the kind you suggest is contemplated. In any event it would not be retrospective, so would not apply to your case.

D. R. W.—We cannot advise legal action since this is both costly and uncertain. A vigorous protest would probably attain your object which is of course the cessation of the annoyance. If you are in a position to show actual damage as the result of the publication an action might lie, but this is a point on which we must refer you to your legal adviser.

LIEUTENANT H.—We do not see that you have any legitimate ground for complaint. Most medical men would have acted in like manner if approached in the way you so graphically describe. In any event the remedy is in your own hands.

A PROTEST.

WE have received letters of protest from two medical men, both of whom complain that their signature has been appended to testimonials in favour of a product known as "Odol," not only without their authority but without their having given any testimonials of the kind. The legal remedy for an abuse of this kind is not very easy to enforce, but we are at a loss to imagine what benefit the proprietors of an article of commerce can expect to derive from publishing fictitious testimonials, which are sure to be promptly repudiated. The moral is obvious, viz., that practitioners cannot be too guarded in their communications with tradesmen whose only object is to push their products without regard to medical etiquette or even ordinary propriety.

H. R. F.—The absence of gonococci is not altogether trustworthy evidence of freedom from infection. Several such tests should be applied at intervals, and the urine should be examined for filaments. Even if all the tests prove negative, a guarded assurance is all that can be given.

Meetings of the Societies, &c.

WEDNESDAY, JANUARY 21ST.

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Great George Street, S.W.).—7.30 p.m. Ordinary Meeting. 7.45 p.m. Report of the Council. Election of Officers and Council for the ensuing year. Address:—Mr. W. H. Dines (President): The Method of Kite-Flying from a Steam Vessel and Meteorological Observations obtained thereby off the West Coast of Scotland.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m. The President will deliver his Annual Address.

THURSDAY, JANUARY 22ND

NEUROLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Annual Meeting. Dr. J. N. Langley: The Autonomic Nervous System (Presidential Address).

FRIDAY, JANUARY 23RD.

CLINICAL SOCIETY OF LONDON. (20, Hanover Square, —).—8 p.m. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 p.m. to 9 p.m.

Appointments.

BYRNE, JOSEPH P., L.R.C.S.I., L.R.C.P.I., House Surgeon to the Dewsbury and District General Infirmary, Yorkshire.

GRÜNBAUM, OTTO, M.A., M.B., B.C. Cantab., M.R.C.P. Lond., D.Sc. Lond., Medical Registrar at the London Hospital.

LYSTER, ROBERT ARTHUR, M.B., B.Ch. Birm., B.Sc. Lond., D.P.H. Birm., Assistant to the Chair of Hygiene and Public Health in the University of Birmingham.

MOON, R. O., M.D., M.R.C.P., Physician to the Out-patient Department of the Infirmary for Consumption, Margaret Street, London, W.

PALMER, HORACE J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg. Medical Officer and Public Vaccinator of the Gamlingay District of the Caxton and Arrington Union, Cambridge

STRATFORD, H. M., M.R.C.S., L.R.C.P. Lond., Senior Resident Surgeon to the Western General Dispensary, Marylebone, N.W.

THOMAS, J. C., M.D., M.R.C.P., Physician to the Out-patient Department of the Infirmary for Consumption, Margaret Street, London W.

Vacancies.

Borough Hospital, Birkenhead.—Senior Resident Male House Surgeon. Salary £100 per annum, with board. Applications to Chairman, weekly board.

Catholic University Ireland Medical School.—Professor of Surgery. Applications to the Registrar. (See Advt.)

Chichester Infirmary.—House Surgeon. Salary £100 per annum, with board, residence and washing. Applications to the Secretary, 9, East Street, Chichester.

County Asylum, Whittingham, Preston, Lancashire.—Assistant Medical Officer. Salary £150. Furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Earlwood Asylum, Redhill.—Two Assistant Medical Officers. Salary of the senior £160, rising to £200. Salary of the junior, £130, rising to £150. Furnished apartments, board, washing, and £5 per annum in lieu of stimulants. Applications to the Secretary, 36, King William Street, London Bridge, E.C.

Fisherton Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.—Applications to Dr. Finch, Salisbury.

Hampstead Hospital.—Resident Medical Officer. Salary £120 per annum, with rooms, coal, and gas.—Applications to R. A. Owthwaite, Honorary Secretary, Parliament Hill.

Manchester Royal Infirmary.—Resident Medical Officer. Salary £150 per annum, with board and residence. Applications to W.L. Saunder, General Superintendent and Secretary.

King's College Hospital, Lincoln's Inn Fields, W.C.—Clinical Pathologist. Salary £250 a year.—Applications to the Secretary.

North Riding Asylum, Clifton, York.—Senior Assistant Medical Officer. Salary £150, with furnished apartments, board, washing, and attendance. Applications to Medical Superintendent.

St. John's Hospital for Diseases of the Skin, 49, Leicester Square W.C.—Superintendent. Salary £200 per annum.—Applications to J. Dunlop Costine, Superintendent.

Saint Bartholomew's Hospital, Rochester.—Assistant House Surgeon. Salary £100 per annum, with board, washing, firing, and light.

Applications to Frederick P. Smith, Clerk, 42, High St., Rochester.

The Royal Victoria Hospital, Dover.—House Surgeon. Salary £100 a year, with board, lodging, and washing. Applications to Arthur B. Elwin, Esq., 2, Castle Street, Dover.

Births.

BRODIE.—On Jan. 12th, at Fernhill, Wootton Bridge, Isle of Wight, the wife of C. Gordon Brodie, F.R.C.S., of twin girls.

SURRIDGE.—On Jan. 15th, at Knutsford, Cheshire, the wife of E. N. Surridge, B.A., M.B., B.C., of a son.

Marriages.

ANDERSON—HARPER.—On Jan. 15th, at St. Andrew's Church, Norwood, John Kingdon Anderson, of 5, Cleveland Square, London, to Anna Reid, eldest daughter of James Peddie Harper, M.D., of 43, Hertford Street, Mayfair

BENNET—HILL.—On Jan. 14th, at Emmanuel Church, Saltburn-by-the-Sea, Robert Allan Bennett, M.B., youngest son of the late P. D. Bennett, Esq., of Edgbaston, Birmingham, to Ethel Jane, elder daughter of John Hill, Esq., of Saltburn-by-the-Sea

LOXLEY—FIELDEN.—On Jan. 15th, at Shildon Parish Church, the Rev. Francis Edwin Loxley M.A., rector of Byers Green, son of the late John Thomas Loxley, solicitor, of Doncaster, to Constance, youngest daughter of Samuel Fielden, M.D., J.P., of Enfield Lodge, Shildon

ROUTH—PINNIGER.—On Jan. 15th, at St. Saviour's Church, St. George's Square, London. Charles Frederick Routh, M.D., of Southsea, son of the late Charles Routh, of Blackheath, to Evelyn Mary, only daughter of the late Rev. H. H. Pinniger, of Whitchford, Warwickshire.

SCOTT—WRIGHT.—On Jan. 16, at Wallasey Parish Church, Cheshire, Samuel Geoffrey Scott, M.A., M.B., Oxon. of Leeds, to Marjory, eldest daughter of Albert T. Wright, of Wallasey, Cheshire.

SWAN—MCCAUSLAND.—On Jan. 14th, at St. John's Church, Blackheath, William Travers Swan, Major R.A.M.C., to Muriel, only child of the late Lieut.-Colonel D. Downes McCausland, 98th Regiment.

Deaths.

BISHOP.—At Elham, near Canterbury, Kent, after a short illness, William Bishop, L.R.C.P., in his 48th year.

BURY.—On Jan. 17, at Whetstone, Middlesex, Henry Charles Bury, M.R.C.S. Eng., L.S.A., aged 62 years, second son of the late George Bury, F.R.C.S. Eng.

DANE.—On Jan. 10th, at Kurrachi, Sind., Colonel A. Dane, Indian Medical Service, second son of the late Surgeon General Dane.

OWEN.—On Jan. 16, Charles L. C. Owen, M.R.C.S., L.R.C.P., Junior Resident Surgeon, Royal Sea Bathing Hospital, Margate.

The Medical Press and Circular.

Original Communications.

GYNÆCOLOGY AS A SPECIALITY. (a)

BY SIR J. HALLIDAY CROOM, F.R.C.S. Edin.,
F.R.S.E.

I THINK I may congratulate you upon the work which the Society has accomplished during the past year. And specially would I like to say that the specimens which have been shown and discussed have been exceedingly valuable and most instructive. I think there is more to be learnt from the careful discussion and exhibition of specimens than probably from the actual reading of papers. At the same time I think that the interests of the Society might be further enlarged by what I should call "clinical evenings." It is not, of course, possible to exhibit patients at our meetings so as to enhance—as the members of other medical societies can do—the value of their papers, but I think we might often set apart meetings for the discussion of purely clinical matters, meetings at which those of our Fellows engaged in general practice, and not only such as are operative gynæcologists, might take a prominent part. Although, as its name implies, the Society is a society for specialists, yet its *personnel* includes a number of men who are not specialists. I think, both for their sake, and the sake of the specialists also, that papers on subjects of a less purely operative and scientific character than those generally brought before us might with advantage be introduced.

That specialism in medicine is needful, and that to specialising we owe a great advance in medicine, there is no doubt. The need for specialism arises from the vastness of the field of work which is opened to us. And this vastness of the field, this great increase of scientific knowledge, is largely due to the enormous changes that have taken place in our means of obtaining this knowledge.

No more interesting memoir has been published of late years than that of Sir James Paget. It is full of interest from beginning to end, but what most interested me in reference to our own department of medicine was the fact that Sir James Paget was, in his early days, as regards the rest of the scientific world, in a position of most "splendid isolation," for he tells us how exceedingly few, even of his teachers, had any knowledge of a foreign language, and how he—a first year's hospital pupil—was invited by men like Marshall Hall and Kernan to go to their private houses and translate to them some of Johannes Müller's works. And he relates how Stanley, then lecturing at St. Bartholomew's Hospital, not only on anatomy, but also on physiology, was indebted to this mere beginner for information about many of Müller's discoveries, which, as Paget aptly remarks, Stanley incorporated into his lectures, as one might now tell the latest and rarest telegraphic messages from some distant field of great research.

(a) Valedictory Address to the British Gynæcological Society, delivered, January 8th, 1903.

You will see, therefore, that it was possible for Paget in his early days to be not only a physiologist and a pathologist, but also a surgeon. It is due entirely to his extraordinary and almost unique powers of work that Paget stands out pre-eminently as the latest and most able representative of this old order, and also as the man whose genius enabled him to become the pioneer of the existing order of affairs, for, though it was said of him by one so well qualified to give an opinion as Sir Richard Owen, that he might be the first physiologist in Europe, Paget, when, after many weary years of waiting, got really into private practice, gave up his physiological work altogether, except in so far as it had indirectly through pathology a bearing on the practice of his surgery. But Paget saw greater changes than this partial separation between scientific research and practical work, and was one of the very first to recognise the field of specialism in surgery. For, long before he gave up operating, he had given up doing special operations, and that, he tells us, for the reason that whereas in his younger days he could frequently say with regard to his scientific reading that he "had read everything" bearing on the subject, he found in his later days, as science became more cosmopolitan, that no man could keep abreast of the advances in all departments.

This subdivision of surgery, beginning shortly after the middle of the last century, went to such an extreme that, in the century's closing decades, it seemed as if the old familiar general surgeon would almost become extinct. It was in this period of the multiplication of specialists that the gynæcologist arose, and now, when we are face to face with the fact that the multiplication of specialists has reached its limit, and that some classes of so-called specialists must return to the decimated ranks of the general surgeons, it would be well to consider some points in connection with this question as it affects our own department.

Gentlemen, whatever our future may be, whatever the future of the youngest branch of surgical science may be, or whatever place it may occupy in the sciences, one thing remains, that in its short lifetime it has made more substantial and remarkable progress than any other branch of surgery, and I think I may with perfect safety claim that our society has played no inconsiderable part in this consummation, and I have only to recall the names of Tait, and of others who are still with us, whose names are for ever associated with the advancement of the science, to make good this claim.

Now, gentlemen, how does the matter at present stand. The gynæcologist, little by little, is encroaching on the domain of the surgeon, and the surgeon is equally rapidly encroaching on the domain of the gynæcologist. Where is this to end? If it is competent for a general surgeon to do hysterectomy, then I presume it is equally competent for a gynæcologist to do gastrostomy.

It seems to me that in this dispute somebody must yield—either the surgeon must absorb gynæcology once and for all, or the gynæcologist must become a general surgeon. Gentlemen, it is not so abroad; one of the best operators that I know is Ségond, and is not Ségond

a general surgeon? Doyen undoubtedly began as a gynaecologist, but now no part of the human body—from the cranium to the sole of the foot—is beyond his interference. The same obtains among provincial surgeons in England, and perhaps I may be allowed to instance my friend, Mr. Mayo Robson, and, among many others, I believe Fellows of our own society. Of course, obviously, where the general surgeon must inevitably find his difficulty in gynaecology pure and simple, is his necessarily meagre acquaintance with pregnancy and local examination, and therefore it must be obvious that the surgeon must, in many cases, fall back upon the obstetrician to have the knotty problem of pregnancy excluded. The want of this knowledge on the part of the operator has given rise to more mistakes within my own knowledge than I care to refer to. In Edinburgh, those who practice gynaecology are also obstetricians. The Professor of Midwifery, who is *facile princeps* of operators north of the Tweed, not only is a consultant in obstetrics, but he practices obstetrics as well, and all his followers, of whom every specialist in Edinburgh is one, have followed his excellent example. We have all held our posts for longer or shorter times in the Maternity Hospital, and therefore, practising as we do in Edinburgh, both obstetrics and gynaecology, that difficulty, of course, does not arise.

I have heard it said that gynaecology, pure and simple, is not a field sufficiently large to support a gynaecological surgeon. Probably it is not, but associated with obstetrics, it is a sufficiently large speciality. Of course, I quite recognise that a man doing a large practice in obstetrics would find some difficulty in overtaking gynaecology as well, but then no consulting obstetrician ought to have a large midwifery practice.

What, then, is the outcome of the matter? By the very meaning of the word, a gynaecologist means one who interferes with the organs that are the special property of women. I am not aware that the appendix, or the liver, or the kidney, or the stomach, are different in the one sex and the other, and I do not see, therefore, that they need necessarily come under the domain of the gynaecologist at all. What belongs to him, is the uterus and its appendices, and indeed, the whole genito-urinary tract. That, combined with obstetrics, leaves a man ample room to specialise. On the other hand, if the old Latin proverb is true, *Nihil humanum a me alienum puto*, and if the whole abdomen is to be the field in which the gynaecologist is to work, then, gentlemen, it is clear that we must cease to be gynaecologists and become simply abdominal surgeons, but why only abdominal surgeons? Why not general surgeons?

I know perfectly well that in what I am saying I lay myself open to misconception as apparently not appraising at its full value what the surgical gynaecologist has done, and what surgical gynaecology has gained as a separate branch. As I have said, I am fully alive to that, but at the same time, I should like to say now, that it having finally become, I might almost say a perfected science, is it to be handed over to the general surgeon, or retained still as a separate branch? If it is to be handed over to the surgeon, then there is nothing more to be said. If it is to remain as a speciality, I think it should be associated with obstetrics.

If the gynaecologist is to proceed from the uterus and the ovaries to the appendix, from the kidney to the gall-bladder and the stomach, I would like to know how much surgery is to be left for the surgeon! If on the other hand, the surgeon is to proceed from the stomach till he has reached the perineum, I wonder how much gynaecology is left for the gynaecologist? Therefore, I think the time is rapidly coming when gynaecology must do either one of two things: it must remain a speciality, and therefore more or less associated with obstetrics, or it must become an integral part of surgery. This is a question which seems to be a very pressing one, and requires some careful consideration.

Again, gentlemen, may I venture to draw your attention to the fact that a certain amount of gynaecology must remain entirely medical and not surgical. To say nothing can be done for a woman except by the surgeon's knife is preposterous. There is a medical

gynaecology as well as a surgical. The trend of the present day is to ignore this to a great extent. How many diseases of women can be treated and benefited by climatic influences, by dieting, by medicines of various kinds? The man who practises obstetrics may have, and ought to possess, a general knowledge of gynaecology, but he need not on that account be an operative gynaecologist. He may see scores of sick women and cure many without any operative interference whatever.

Personally, my own position is this: I practice obstetrics and gynaecology pure and simple, but when a case occurs in which the diagnosis is uncertain, and where it might involve the removal of the kidney or an appendix, I think that I would associate myself with an ordinary surgeon, just as the surgeon often associates me with cases where the case is purely gynaecological.

To state an example. Not many weeks ago I removed a large ovarian tumour from a patient, who, four weeks afterwards, developed a femoral hernia. I had completed my part of the work, and therefore I handed this femoral hernia over to a colleague.

Some time ago a surgeon had a difficulty about an appendicitis which might, he thought, involve the ovary, and he associated me with him in his operation.

Although I confess to have trespassed on the surgeons now and again, at the same time my own position is that I practice obstetrics and gynaecology pure and simple. I am willing to undertake anything in those two branches that may present itself to me.

My friend, Dr. Macnaughton-Jones—and there is no one to whom this Society owes more—in his preface to his excellent book, regards the matter from another standpoint, a standpoint which I can quite understand.

He says in his book, "Gynaecology as now practised covers in its operations a much larger field than would be included by the treatment of the pelvic organs alone. This widening of its sphere resulted as a natural consequence of the many abdominal complications met with in connection with pelvic diseases.

"Operations for the latter revealed errors in diagnosis which compelled the gynaecologist to deal with unforeseen conditions and complications that practically involved the entire surgery of the abdomen. Tumours of the spleen, morbid states, growths and displacements of the kidney, affections of the intestines complicating uterine tumours and adnexal disease, or unavoidable accidents to the bowel arising in the course of an operation, all necessitated immediate action on the part of the surgeon when the abdominal cavity was opened. Thus the surgery of the spleen, kidney and bowel, as well as of the generative organs, the rectum, the ureter and bladder, has of necessity to be included within the range of modern gynaecology."

If this statement is an accurate description of modern gynaecology, either actual or ideal, then we must reconsider our position very carefully. I must say at once, looking back over experiences—considerably over a thousand abdominal sections—I have not met with the complications that Dr. Macnaughton-Jones refers to, but I can quite understand, of course, that such can occur, and I therefore understand his position entirely.

If this be his position, then it seems to me that we should range ourselves as a department of surgery pure and simple, and call ourselves, as Dr. Macnaughton-Jones suggests, abdominal surgeons; for if the gynaecologist is to operate on the spleen and kidney, &c., in women, then why not on men, if the same condition exist in the male abdomen? If we have become abdominal surgeons, alike for both sexes, we can scarcely claim the style and title of gynaecologists. If we countenance this aggression in our colleagues' domains, we shall be powerless to resist the incursion of the general surgeon into the female pelvis.

I am not venturing for one moment to criticise the position of any of my colleagues, but I wish to point out that I think our position in Edinburgh is a more reasonable one, because there each of us professes obstetrics and the diseases of women, nothing more and nothing less. Every one of my colleagues, with, I think, a single exception, practises midwifery as well as gynaecology, and with that, I think, no exception can be taken.

Mark me, gentlemen, we claim to be a gynæcological society, and, being so, I think there is no reason why general surgeons should not belong to our society, but, at the same time, what I want to know, and what I think there should be a pronouncement of our society upon, is: What is a specialist in gynæcology?

Gynæcology, of course, covers obstetrics, and I call a specialist in gynæcology one who practises nothing but midwifery and diseases of women—that and that alone. Of course it may be asserted with perfect propriety that the gynæcologist has now been absorbed by what we call the abdominal surgeon; if that is so, then, as a body of men, we have ceased to exist.

There are, therefore, three possibilities: First, obstetrics and gynæcology may be absolutely divorced; secondly, men may practise gynæcology, so-called, operating only, interfering only, with the organs of reproduction; or, lastly, gynæcologists may become absorbed in the general surgeons, specialising to a certain extent as abdominal surgeons.

Gentlemen, I venture to bring this question before you this evening that we may ventilate the subject, because, it seems to me that the time has arrived when we should take up either one position or another. I do not venture to say which is the best one; I only venture to bring before you the position which the school to which I belong has uniformly adopted.

I shall be glad to hear what you think of it.

A CASE OF LEUKÆMIA IN A BOY, ÆT 3½ ASSOCIATED WITH TUBERCULOUS MESENTERIC GLANDS. (a)

By GEORGE CARPENTER, M.D. Lond.

Physician at the Evelina Hospital for Sick Children.

LEONARD P., æt. 3½, was admitted into the Evelina Hospital on July 7th, 1901. He had been ill for five weeks, and his pallor on admission was extreme. Tuberculosis was stated to be present on the maternal side of the family, and there had been instances of it on the paternal. His father, so it was stated, had always been pale, and his two paternal aunts suffered from anæmia badly. There was no history of malaria or syphilis. The child was healthy at its birth, it was fed on the breast for nine or ten months, and passed through an uneventful infancy. There was nothing worthy of note in his dietetic history, and his hygienic environment was always quite satisfactory. Five weeks before being brought to the Evelina Hospital his mother noticed that he suddenly, as she states, became quite pallid; but his appetite at this time was fairly good. A fortnight later he developed a croupy cough; then he became languid and would not take his food. A doctor now saw him and pronounced him to be anæmic; he was treated for this for a short time and was then brought to the Evelina Hospital. During this latter period of his illness he lost flesh and was thirsty, and for three days prior to his admission into the hospital he passed through an attack of sickness. His abdomen also became painful, but only sufficiently so to make him cry on one occasion. He was also at this time so short of breath that he could not walk.

On examination he was found to be a very pallid child with white lips, pale gums, and a complexion of a lemon-yellow colour. He was dark and puffy-looking under the eyes, the sclerotics of which were

bright and glistening. There were some bruises on his trunk and limbs. He was very restless, constantly shifted his position in his cot, and flung his arms and legs about. His abdomen was distended. The free edge of the *spleen* could be felt from two to three fingers' breadths below the costal margin, and the *liver* free edge was felt to a similar extent below the costal margin in the nipple line. The accessible *lymphatic glands* were not enlarged. The *heart* showed some epigastric pulsation, and there was a systolic hæmic bruit which was best heard over the left fourth and fifth intercostal spaces. The second pulmonary sound was loud. There was a trace of albumin in the *urine* on his admission, but this was only observed on that solitary occasion. His temperature was 99.4° F., the pulse-rate was 128 to the minute, and the respiration-rate 28 to the minute.

The *blood examination* was as follows: Red corpuscles, 1,568,111 per cmm.; hæmoglobin, 15 per cent.; colour index, 0.5. White corpuscles, 130,111 per cmm., the ratio being 1 to 12. Fresh films showed an increase of the white corpuscles, and the red were in rouleaux. There were no microcytes or poikilocytes. Stained films showed an increase of leucocytes, mainly small lymphocytes. There were a few polymorphonuclear leucocytes and myelocytes, and some doubtful nucleated red corpuscles (megaloblasts). During his short stay in the hospital his temperature was somewhat above normal, the highest point registered being 100.2° F. His respiration-rate varied between 28 and 44 to the minute, and his pulse-rate between 126 and 152 to the minute. He was sick on one occasion, and once he complained of pain in the left side. On the evening of the 14th he became collapsed, and made frequent complaints of pain in his abdomen. At 9.30 p.m. he commenced to scream and throw his arms about, and was noticed to be squinting. After a dose of morphia he became quieter and slept until 2 a.m., at which time he was very thirsty and constantly craved for drink; subsequently his head was bathed with profuse perspirations, and he started screaming again at 3.30 a.m., and then his pulse was barely perceptible at the wrist, and his respirations were gasping. He died somewhat later.

The *post-mortem examination* was made by Dr. Nabarro, eleven hours after death. The body nourishment was good, and there were no signs of decomposition. The body was extremely pale, and there were several purple-coloured bruises on the legs and one over each frontal eminence. The *nervous system* was not examined, by request. There were petechial hæmorrhages all over the surface of the *heart*; it contained pale clots and clear serum. The valves were healthy. The cavity of the left ventricle was dilated. The heart muscle was very soft and pale, and "tabby-cat" striation was slightly marked in the papillary muscles. The *blood* throughout the body was pale. The *bronchial glands* were enlarged and very dark, as though some hæmorrhage had occurred into their substance. There were several ounces of clear fluid in each *pleural cavity*, and sub-pleural ecchymoses were present on the surface of both *lungs*. On section the lungs were somewhat œdematous. There were no clots in the *pulmonary artery* or its branches. The *stomach* showed some submucous hæmorrhages. The *intestines* displayed unduly prominent Peyer's patches and lymph follicles.

(a) Read at the meeting of the Society for the Study of Disease in Children, November 21st, 1901.

The jejunum appeared to be thinner than normal. The lymphatic tissue in the large intestine, as in the small, was in excess, and a few small ulcers were present in the large and small intestines. The *mesenteric glands* were very considerably enlarged. They were pale in colour and the largest of them were caseating in the centre. The *liver* was large and very pale. The *spleen* was large, it weighed 4 ozs., and was normal in appearance. The *supra-renal bodies* were normal. *Kidneys*.—The right kidney was very large and weighed 5½ ozs.; its surface was covered with ecchymoses, and its capsule was not adherent. On section the cortex was greatly thickened. The left kidney was similar, but larger; it weighed 6½ ozs., and at its upper part was flattened by pressure from the spleen. The *pancreas* was normal. *Lymphatic glands*.—Many small glands were present along the course of the abdominal aorta and iliac vessels, and also in the groins and the axillæ. They were not caseating. The *thymus* was apparently normal.

A piece of a rib was removed; on section the marrow was pale, but apparently normal. *Cultivations* were taken from the right ventricle, but yielded negative results. *Microscopical examination* of the thickened renal cortices showed extensive leucocytal infiltration.

THE PROGNOSIS OF TUBERCULOUS PERITONITIS IN CHILDREN. (a)

By G. A. SUTHERLAND, M.D.,

Physician to Paddington Green Children's Hospital; Assistant Physician, North-West London Hospital.

THE prognosis of tuberculous peritonitis is a subject on which many and diverse views have been expressed. The great question as to whether the disease tends to run a favourable or an unfavourable course may be said to be still unsettled. Twenty-five years ago the prognosis was regarded as hopeless. Ten years ago it was considered more hopeful, especially under surgical treatment. To-day we are still searching for more light, and although extensive statistics have been compiled on the Continent, which have considerably influenced opinion in this country, there are comparatively few published from English hospitals. I propose to limit my remarks on the prognosis to the results of a study of forty-one cases of tuberculous peritonitis treated as in-patients at Paddington Green Children's Hospital. These represent all the cases of that affection which are available for statistical purposes from that hospital, a few having been rejected because the diagnosis was uncertain or the period under observation was too brief.

The first important point in the prognosis is to ascertain the proportion of recoveries to deaths. In these forty-one cases there are—

| | | |
|------------|-------|-------------|
| Recoveries | | 29 or 70·7% |
| Unrelieved | | 1 or 2·5% |
| Deaths | | 11 or 26·8% |

If the results of medical treatment are compared with those of surgical treatment, the statistics are—

| | | |
|------------------------------|-------|-------------|
| Medically treated, 27 cases— | | |
| Recovered | | 22 or 81·3% |
| Unrelieved | | 1 or 3·7% |
| Died | | 4 or 15·0% |

Surgically treated, 14 cases—

| | | |
|-----------|-------|----------|
| Recovered | | 7 or 50% |
| Died | | 7 or 50% |

In the case of a chronic affection like tuberculous peritonitis, it can hardly be deemed correct to use the term "recovery" when the patient leaves the hospital or convalescent home; "apparently on the road to recovery" would be as far as one can safely go. The cases, therefore, have been followed up as well as possible after leaving the hospital, and the statistical results, both favourable and fatal, are drawn up after keeping the patients under observation for the longest possible time. The cases which are entered as "recovered" were under observation for the following periods:—

| | | |
|--------------------|-------|---|
| Under 3 months | | 2 |
| From 3 to 6 months | | 7 |
| „ 6 to 12 months | | 1 |
| „ 1 to 2 years | | 4 |
| „ 2 to 3 „ | | 4 |
| „ 3 to 4 „ | | 1 |
| „ 4 to 5 „ | | 4 |
| „ 5 to 6 „ | | 3 |
| Over 6 years | | 3 |

Total 29

Considering the number of cases which were under observation for a year or longer—namely, 19, or 65·5%—it will perhaps be admitted that the term "recovery" is justified. Further, in those cases the signs of active disease had ceased, the traces of local disease became less evident with each succeeding year they were observed, and the general strength seemed steadily to improve.

The Natural Course of Tuberculous Peritonitis.—Tuberculous peritonitis in its uncomplicated form is an affection which lasts usually from six months to a year, or longer. The natural course of the disease in a fairly healthy child would appear to be towards ultimate recovery. Perhaps in no form of tuberculosis does Nature make greater or more successful efforts to cope with the disease. The formation of fibrous tissue is Nature's method of shutting up the tubercles, cutting off their supply of nourishment, and starving them out. When their vitality is gone and all active peritoneal tuberculosis has ceased, Nature next directs the powers of the body to the absorption of the dead tubercles and the fibrous tissue surrounding them. Sometimes the effort is completely successful, sometimes the absorption is only partially complete, and sometimes complications arise from outside causes which put an end to the process. If this process of fibrosis is to be regarded as the natural course of the illness towards a favourable issue the prognosis will depend on the patient's powers of furthering it. Consequently, a strong family history of tuberculosis, or an infancy passed under bad hygienic and dietetic conditions, or a constitution of slight resistant power, or a history of one or more severe attacks of infective fever during early life must be regarded as a factor which influences unfavourably the prognosis in any given case.

The Prognosis in Uncomplicated Tuberculous Peritonitis.—The disease presents itself under various clinical aspects. There may be an acute onset, with typhoid-like symptoms, followed by a very severe illness, characterised by ascites, abdominal distension, diarrhoea or constipation, and high temperature. Although one would hesitate to speak decidedly during the acute stage of the

(a) A paper read before the Society for the Study of Disease in Children.

illness it is not uncommon for such cases to terminate in complete recovery. Most of the cases begin insidiously. The ascitic type, in which fluid is poured out more or less freely owing to the irritation produced by many scattered tubercles, is one in which the prognosis is favourable if it is succeeded by a fibro-plastic formation, which is the natural termination. Those cases in which the fibro-plastic formation is active from the start do well as a rule. Cases of tumour formation, rolled up omentum, or puckered up mesentery, or matted intestine may present no active symptoms, are extremely chronic, and usually terminate favourably. A common clinical type is that in which tuberculous pleurisy is an associated condition, and the prognosis does not appear to be unfavourably influenced by this association.

Various symptoms in the course of the disease affect the prognosis. A favourable condition may be said to be present when the *temperature* is sub-normal, or normal, or only slightly raised, and even when there is a considerable evening rise to 102° or 103°, it is wonderful how well and how long the patient will hold his own, provided there is a daily remission and a pyrexial period. On the other hand, continuous pyrexia, even of moderate degree, is unfavourable, is usually accompanied by progressive loss of strength, and is suggestive of some complication. A continuously rapid pulse, over 110 per minute, is to be regarded as indicative of acute abdominal disease, and is of unfavourable prognostic significance. *Diarrhœa*, when prolonged, is of bad omen, and suggests one of the gravest complications, tuberculous ulceration of the bowel. Great *distension of the stomach and intestines*, when paralytic in origin, is of unfavourable significance; when it is obstructive in origin it may be amenable to surgical treatment. *Rapid wasting* must be looked on as an indication that the disease has gained the upper hand locally, or is becoming generalised. The defensive powers of the constitution are invariably weakened in the presence of rapid emaciation. *Recurrent attacks*, with or without marked pyrexia, affect the prognosis unfavourably. They tend to exhaust the resistant powers of the patient, and they point to fresh infection from an active, although possibly unrecognised source.

The Prognosis in Complicated Tuberculous Peritonitis.—The complications which may precede or arise from tuberculous peritonitis seriously affect the prognosis, and one or more of them will usually be found to be present in the fatal cases.

1. Tuberculous ulceration of the intestine. This may be small in extent and not associated with any marked symptoms. When it is extensive, as indicated by intractable diarrhœa and the passage of blood and mucus, the prognosis is unfavourable.

2. If extensive caseation of the mesenteric glands or of tuberculous masses exists, recovery is delayed, fresh infection of the peritoneum is apt to occur, and the risk of abscess formation and rupture is constantly present.

3. Local suppuration, from infection through glands or the intestine, is a complication which, if unrelieved by surgical treatment, is apt to retard recovery and lead to more serious complications.

4. Obstructive symptoms from intestinal matting or the pressure of tuberculous growths are, as a rule, not marked. If progressive and unrelieved, the prognosis is bad, but surgical interference may prove successful in removing all imminent danger.

5. In the presence of pulmonary tuberculosis, with definite physical signs, the prognosis is unfavourable. It must be remembered, however, that dulness and crepitations are frequently present at one or both bases, owing to the diaphragm being pushed upwards, the lower portions of the lungs being thrown out of action, and congestion occurring in consequence. With the relief of the abdominal distension these pulmonary signs will usually disappear entirely. The prognosis is very bad in the case of the following complications:—

6. The rupture of a glandular or other abscess, or the perforation of an intestinal ulcer into the general peritoneal cavity.

7. The onset of tuberculous meningitis.

8. The occurrence of general miliary tuberculosis.

As confirming the serious prognostic influence of the various complications, the causes of death in the fatal cases may be given here. Six of the eleven cases were examined post mortem:—

| | |
|---|----------|
| Purulent peritonitis from intestinal perforation or ruptured abscess | 5 cases. |
| Intractable diarrhœa (? Intestinal ulceration) | 2 " |
| With cerebral symptoms (? Tuberculous meningitis) | 2 " |
| Tuberculosis of peritoneum, pleura, and lung, with partial intestinal obstruction by a band | 1 " |
| Cause unknown | 1 " |
| Total | 11 " |

The Prognosis as Affected by Medical Treatment.—The results of medical treatment as given above may be regarded as favourable. If the prognosis in uncomplicated tuberculous peritonitis depends on improving the patient's resistant powers as much as possible until the tuberculous process is checked, and increasing his aggressive powers until the tuberculous products have been entirely removed, it is plain that medical treatment directed to these ends will be of the highest importance in making the prognosis more favourable. In the complicated forms of the disease medical treatment is of less direct value.

The Prognosis as Affected by Surgical Treatment.—In the complicated forms of tuberculous peritonitis, the prognosis is much more serious, and here it is that the prospect may be entirely changed by surgical interference. One striking case is before me, that of a girl, æt. 3, on whom Mr. Watson Cheyne performed laparotomy for obstruction, and short-circuited the small intestine. The patient made an excellent recovery. In another case, with suppurative peritonitis from a perforation of the cæcum, a fatal termination ensued.

As regards the surgical treatment by simple laparotomy—the so-called cure for tuberculous peritonitis—our results are not good, namely, six recoveries and six deaths. It is not suggested that the fatal results were due to the laparotomy, for the deaths occurred at periods of from one to six months after the operation. But it is clear that the operation was ineffectual in preventing the complications which led to a fatal termination. The cases which recovered may be said to have done so in spite of the operation, for they presented in their post-operative stages no striking changes

and no clinical developments which could not be equally well observed in the cases treated medically. At one time I was a supporter of laparotomy as a routine treatment, but further experience has altered my opinion. A girl, *æt.* 6, the subject of fibro-ascitic tuberculous peritonitis, was considered a suitable case for laparotomy, but operation was deferred for unavoidable reasons, and she was sent to the country. While she was there the abdominal contents became harder and denser, until they felt like plaster-of-Paris, the fluid disappeared, and the girl improved. Some months later she was so much better that operation was not considered necessary, and during the next year there took place a gradual absorption of all the dense material until finally she was quite restored to health and the abdomen to a normal condition. In other cases before me, cases of acute tuberculous peritonitis, of tumour formation, of the ascitic type and of the fibrous variety, I find that as good results may follow from medical as from surgical treatment, and I do not find that the course of the disease is appreciably affected by laparotomy. From the post-mortem evidence also it is plain that, whether the case was medically or surgically treated, death was not due to uncomplicated tuberculous peritonitis, but to some complication beyond relief either by medical measures or by laparotomy.

The conclusions drawn above may be summarised as follows:—

1. In uncomplicated tuberculous peritonitis the prognosis is good.
2. When tuberculous pleurisy is present the prognosis is still favourable.
3. The prognosis is rendered less favourable in the case of (a) a strong family history of tuberculosis; (b) an infancy passed under bad hygienic and dietetic conditions; (c) a constitution of feeble resistant power; or (d) a history of severe infective illness in early life.
4. The prognosis is rendered less favourable in the presence of one or more of the following symptoms: continuous pyrexia, rapid wasting, persistent diarrhoea, rapid pulse, and recurrent acute exacerbations.
5. The prognosis is rendered less favourable in the presence of one or more of the following local complications: (a) tuberculous ulceration of the bowel; (b) extensive caseation of the mesenteric glands or of tuberculous masses; (c) localised suppuration from infection through glands or the intestine; and (d) obstructive symptoms from bands or matting of the intestine.
6. The prognosis is bad in the case of the following complications: (a) the rupture of a suppurating gland or the perforation of an intestinal ulcer into the peritoneal cavity; (b) pulmonary tuberculosis; (c) tuberculous meningitis; and (d) general miliary tuberculosis.
7. In tuberculous peritonitis the prognosis is not appreciably affected by simple laparotomy.

It is stated that the Health Officers of twenty-one States, in conference at Washington, have resolved that California must forthwith eradicate the bubonic plague or submit to general quarantine. The existence of plague has been denied, but the Federal Health Bureau reports ninety-three cases in three years, all starting in Chinatown, San Francisco. Of twenty-two dead rats examined there, eleven were found to be infected.

EXCISION OF CARCINOMA OF THE RECTUM AND THE TREATMENT OF INOPERABLE CARCINOMA OF THE SIGMOID FLEXURE. (a)

By F. M. CAIRD, M.B., F.R.C.S.Ed.

Assistant Surgeon, Royal Infirmary, Edinburgh, Lecturer on
Surgery, Edinburgh Medical School.

CARCINOMA of the rectum was one of the more slowly growing cancers, therefore early operation was strongly to be advised. In later stages a palliative colostomy was alone possible. Most cases of rectal cancer lay above the internal sphincter, but it was almost invariably possible to reach beyond them with the fingers. When the tumour had the above position the para-sacral excision—the sacro-sciatic ligaments being divided by a lateral incision, and parts of the coccyx and sacrum removed if need be—was the best operation. It was not difficult to deal with posterior adhesions, but those in front of the growth often gave rise to great difficulty. A sound should be held in the bladder as a guide to its position. Very often a great deal of the surrounding thickening was not malignant but inflammatory, and disappeared after the removal of the tumour. A mesial laparotomy might be required for diagnostic purposes, but as a rule it was possible to delimit the tumour from the rectum. A few enlarged glands out of reach of the knife should not deter one from attempting a radical cure, because these glands were not seldom due to septic absorption from the ulcerated surface, and therefore had not the same significance as glands following scirrhus of the breast without ulceration. If the patient's condition warranted operation it should be done without delay, and too much time should not be spent on preparation. Sepsis was the chief risk, and therefore the bowel ought to be thoroughly washed out at first, the surgeon using rubber gloves while doing this, so that his hands might not be contaminated. At the same time, he uttered a word of warning against the use of even dilute solutions of lysol in too great abundance, as he had once seen dangerous collapse follow an injection of this antiseptic, which was not immediately returned from the bowel. In females it was seldom necessary to remove more than the coccyx; in males, owing to the smaller pelvic outlet, a more extensive resection of bone might be needed. He thought it was a most important matter to open the peritoneum early so as to get well above the tumour at once. The space was packed with iodoform gauze so as to cut off the peritoneal cavity from the field of operation. If the cut edges of the bowel could be approximated a continuous suture was best, and an effort should be made to unite at least their anterior parts. If this was impossible an artificial anus ought to be left in the sacral region. He had had ten cases of this operation without a death. Perfect results—complete control of the action of the bowels—was got in four women and one man; in four men and one woman the results were unsatis-

(a) Paper read before the Edinburgh Medico-Chirurgical Society, January 7th, 1903.

factory in this respect. As to the future history, one died within six months, and three within a year, the remainder at later periods up to four or five years. It must be remembered that stricture of the bowel was a not uncommon sequence of the operation, and might simulate local recurrence.

In cases of carcinoma at a lower level excision of the whole sphincter by the peritoneal route might be required. Here, also, the pouch of Douglas should be opened early. Of four such operations (none immediately fatal) two cases died within the year and the others within eighteen months. He had had one fatal case of combined para-sacral and perineal operation.

Inguinal Colostomy for Inoperable Cancer.—In six cases in which it was undertaken for impending obstruction four patients died and only one recovered, figures which sufficiently demonstrated the danger of delaying until the condition of things had reached such a pass. When done in the quiescent stage its success was very great, and the comfort experienced, especially if compared with the old operation of lumbar colostomy, was very marked. The colon should certainly be cut completely across, so that no fæces were passed down into the rectum. In many cases the patients could live in comparative ease, and in some resume work and social duties with an artificial anus in the iliac region. Passing to the special symptom, he wished to dwell on two points. In some cases the disease closely simulated prostatic enlargement, the symptoms being entirely referable to the bladder. In the second place a cancer of the rectum was sometimes secondary to another growth in the alimentary canal. It was not common for a primary cancer of the intestines to give rise to metastases in the bowel; if these were found they were perhaps most common in the rectum and œsophagus. Finally, he wished to refer to the dangers of iodoform poisoning. No agent could replace iodoform gauze in these cases. It had great powers of bringing about peritoneal adhesions, and he had never felt justified in replacing it by orthoform or any of the newer drugs. It must, however, be used cautiously, as great depression or acute mania might develop. The urine ought, therefore, to be tested for iodine daily while iodoform was being used.

Clinical Records.

A CASE OF EXTROVERSION OF THE BLADDER. (a)

By MR. W. H. STILES, F.R.C.S.Ed.,

Surgeon to the Royal Edinburgh Hospital for Sick Children.

In this case the ureters had been transplanted into the rectum by the method of Peters, of Toronto. The case was one of complete extroversion, with epispadias, and a hernia on the one side of the scrotum, while on the other the testicle had not descended. The recent operations for the condition aimed at transplanting the ureters on to the sigmoid flexure or rectum. If the treatment were to be considered successful there must be no incontinence of urine. Two methods were employed, the intra-peritoneal and the extra-peritoneal. The first operation introduced consisted in dividing the ureters individually, and grafting the ends into the rectum. This operation was seldom successful, the danger being an ascending infection and pyelo-nephritis.

(a) Case brought before the Edinburgh Medical-Chirurgical Society, January, 1903.

Magill modified it by excising the trigone of [the bladder with the two ureteral orifices and grafting the whole into the rectum; the risk of infection was thereby much lessened. Peters had recently proposed an extra-peritoneal operation, as follows:— Insert a soft catheter for about an inch and a half into each ureter and secure it in position with a stitch. With the catheters as guides free each ureter with a small disc of mucous membrane for about one and a half inches of its course. The finger is then passed into the rectum and the anterior wall projected towards one of the spaces left by the freeing of the ureters, a slit-like incision is made on the antero-lateral aspect of the rectum at this point, and the catheter is seized with forceps through the orifice and drawn into the rectum and out of the anus. The lower end of the ureter with its attached disc of bladder or mucosa is then drawn through the slit in the rectum. The other ureter is similarly treated. The openings into the rectum should be above the internal sphincter. The urine is allowed to drain through the catheters into a bottle of antiseptic lotion till the wound has healed. In the case shown symptoms of pyelo-nephritis appeared from the fourth to the eighth day, but was recovered from under hot packs, &c. The child could now retain the urine for about three hours. The epithelium of the extroverted bladder was gradually altering its character as the result of being kept dry.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING OF FRIDAY, JANUARY 23RD, 1903.

Mr. HOWARD MARSH, F.R.C.S., President, in the Chair.

CLINICAL EVENING.

A CASE OF HEMIATROPHY FACIALIS (MORPHŒA OR LOCALISED SCLERODERMA OF THE FACE).

DR. T. D. SAVILL showed a man, G. S—, æt. 50, who, in 1880, had a severe blow on the top of the head and thereafter suffered from neuralgic pains in the vertex and face, sometimes of great severity, until 1895, when they subsided under treatment. In 1885-86 he first noticed that the hair of the left side of the scalp and left eyebrow was coming off, and that the face on the left side was becoming wasted. The wasting of the face at first gradually increased, but it has remained stationary for some years. There is no history of alcohol or syphilis. The patient has been a waiter or a "carver" all his life. On the left side of the face the whole of the skin is shiny and smooth, and this, with the subcutaneous tissue, is considerably atrophied. The hair is almost absent from the left anterior quarter of the scalp, and is also wanting in the inner half of the left eyebrow. The temporal and masseter muscles are notably atrophied, but the other facial muscles do not seem wasted. The electrical reactions, as far as can be ascertained, are not affected and the masticatory powers are as good on the left side as on the right. The distribution of the facial atrophy corresponds roughly to the cutaneous distribution of the left fifth cranial nerve. There are three other patches of atrophic skin upon the body, one upon the middle of the back about the size of the hand, which presents a few dilated venules characteristic of morphœa, and in this position there appears to be a slight tendency to excess of pigment. Another patch of atrophied skin may be seen behind the right ear, and a third over the outer side of the left knee. No history is obtainable concerning these, and, like the facial atrophy, they cause the patient no unpleasant sensations.

SIR DYCE DUCKWORTH concurred in Dr. Savill's view of the identity of facial hemiatrophy with morphœa, and referred to a paper which he had communicated to the *Edinburgh Medical Journal* in 1883, in which he had dealt with different forms of atrophy. He

attributed this and other atrophic skin lesions to disease of the nervous system. He also referred to two cases in which the patients had lost the hair all over the body after falling on the back of the head.

CASE OF RUPTURED AORTIC VALVE.

Dr. SEYMOUR TAYLOR showed a man, *æt.* 50, a hammerman, who was admitted on October 26th, 1902, complaining of giddiness, præcordial pain, and dyspnoea. He had contracted syphilis seventeen years ago. He was in good health until July, 1902, when, after a long day's heavy work he complained of pain in the præcordial area and dyspnoea, which became gradually worse. On admission he was found to have a loud aortic obstructive murmur and a louder diastolic murmur. The latter was musical, of low pitch, was attended by a thrill, and was so loud and so wide in its distribution that it could be distinctly heard at a distance of two inches from the chest, and with the aid of the stethoscope it could be heard all over the thorax, back and front, in the abdomen as low as the umbilicus, and as far down the upper limb as the middle of the humerus. There was no evidence of any pulsatile tumour to suggest the existence of an aneurysm. He had dysphagia and no cough. The vocal cords acted symmetrically, and his radial pulses were equal. The left ventricle was hypertrophied and probably dilated, the urine free from albumin and sugar. The diagnosis of ruptured valve is made on the following grounds, *viz.* (1) A history of syphilis. (2) The sudden oncoming of urgent symptoms. (3) The patient's occupation. (4) The musical diastolic murmur. (5) The presence of marked diastolic thrill. (6) The absence of any other definite signs of aneurysm. The exact nature of the rupture can only be conjectural, but it is probably a perforation rather than a complete separation of a cusp from its attachments.

CASE OF REMOVAL OF THE SCAPULA OF A BOY, *ÆT.* 9.

Dr. STEPHEN PAGET showed a lad, *æt.* 9, thin and delicate-looking, but healthy, with a hard nodular mass springing by a broad base from the right supra-spinous fossa, and passing forward beneath the clavicle. No signs of pressure on the vessels and nerves of the arm; no enlarged glands; no history of pain or injury. Operation, April 30th, 1902; excision of scapula; growth found to be cartilaginous. During operation transfusion of three and a half pints of saline fluid. Patient made a good recovery, and the movements of the arm are very good. Sutures removed May 12th. Discharged from hospital May 21st, wearing a support to prevent arm from dropping.

CHARCOT'S KNEE AND SPONTANEOUS FRACTURE OF TIBIA IN THE SAME LIMB.

Dr. H. D. ROLLESTON showed a woman, *æt.* 46, who had had seven miscarriages, the last, eight years ago. Lightning pains came on eight years, and visceral crises six years since. Five years ago painless swelling of left knee after a long walk came on suddenly. Three years ago while going upstairs the left tibia fractured painlessly. Menopause came on last year, and was accompanied by incontinence of urine. Altered character of voice noticed eleven months ago. On December 3rd, 1902, after diarrhoea lasting three days, lost powers in right leg. *Present condition.*—Charcot's arthropathy in left knee. The left tibia, about the middle, shows a projection, the result of the old fracture. Paresis of the right lower extremity. Complete paralysis of the left third nerve. Altered speech. Occasional choking fits. Is subject to attacks during which she feels faint. Optic discs pale. Pupils contracted; do not react to light or accommodation.

A CASE OF TRAUMATIC STRICTURE OF THE OESOPHAGUS, GASTROSTOMY TWO YEARS AFTERWARDS (ALBERT'S METHOD), PERFORMED AT THE LONDON HOSPITAL.

Dr. JOHN R. LUNN showed a seaman, *æt.* 63, admitted on October 21st, 1902, with the following history:—In 1898 he sustained an injury to the front of the neck, and two years afterwards (1900) he began to lose weight, and experienced some difficulty in swallowing. He was X-rayed several times, and a small oesophageal bougie was passed with some difficulty through an

obstruction about 6½ inches from his teeth. About two months after this Mr. Mansell Moullin performed gastrostomy, and he was discharged four weeks afterwards, when he returned to sea, feeding himself by the abdominal opening into the stomach. After the man's arrival in Boston, U.S. (which was about fifteen months after the operation), the wound healed, so he went into hospital there and had it reopened, and was then able to feed himself once more. In 1902, on his way to France, the wound began to heal again, and as he could not pass the tube he tried to dilate the orifice with a piece of wood, which caused pain and bleeding; this apparently caused some local peritonitis. The patient states that on his arrival at Havre in September, 1902, he went into hospital, when the surgeon trimmed the edges of the wound in the abdomen, which was stitched together and closed. When he arrived at the St. Marylebone Infirmary in October, 1902, the stitches were removed and the wound was healed. Since his admission he has gained in weight, and has been able to take solid food, though he gets some dysphagia now and then, and he has still some obstruction (spasmodic) of the oesophagus. About seven inches from the teeth he has some doubtful thickening round the larynx. The patient seems very well in health with the exception of the ventral hernia, which causes him some pain occasionally, for which he wears an abdominal support.

PERSISTENT SLIGHT JAUNDICE OF FOUR YEARS' DURATION IN A GIRL, WITHOUT OBVIOUS ALTERATION IN SIZE OF LIVER OR SPLEEN, AND WITHOUT MARKED IMPAIRMENT OF THE GENERAL HEALTH.

Dr. F. PARKES WEBER showed a girl *æt.* 18, the youngest child of Polish Jewish parents, who suffered from persistent slight jaundice, best marked in the sclerotics of the eyes. The jaundice was first noticed at 14 and since then she has had a tendency to slight bleeding from the nose and gums. Recently she had been subject to headaches. No other definite illness. Menstruation commenced at about seventeen years, but has been irregular and often absent since then. The patient has been under observation since the beginning of November, 1902. At about that time there was a slight irregular fever, but with rest in bed, diet consisting chiefly of milk, and a little chlorate of potassium internally, this passed off in little more than a week. There is no obvious enlargement of liver or spleen, and indeed by physical signs nothing abnormal can be detected in any of the thoracic or abdominal organs. The gums have sometimes been slightly swollen, and have sometimes bled, and a few purpuric spots were on one or two occasions noticed on the limbs. The faces have generally been well coloured, though sometimes pale. The urine, which is free from albumin and sugar, has varied in colour between different tints of sherry, but is generally not very dark; it becomes darker on the addition of nitric acid, and sometimes a slight Gmelin's reaction has been obtained. Blood (November, 1902): hæmoglobin 85 per cent.; under microscope the red corpuscles looked normal, and the proportion of white to red cells was little if at all increased; no abnormal forms of cells were seen. The serum obtained from a blister gave a Gmelin's reaction. No evidence of any congenital deformity in the body can be discovered. There is no clubbing of the fingers. Since the patient has been under observation there has been very little change in the degree of jaundice, but the headaches have been less marked, and for a long time there has been no fever at all. There has never been pruritus or xanthoma. Iodide of potassium in 5 gr. doses three times daily was given during nine days, but was discontinued owing to a pustular eruption; iodides disappeared from the urine two days after the drug was discontinued. On two occasions the patient was given a decigramme of methylene blue, and on both occasions the colour disappeared from the urine very quickly, once in about eighteen hours, once within two days. The ingestion of 100 grammes of glucose failed to produce any alimentary glycosuria. The case seems to

resemble those described by French authors under the heading "simple cholæmia," but unlike some of this class, in the present case the jaundice is not congenital, and is not known to exist in other members of the patient's family. The pathogeny of such cases is not known, but the jaundice may apparently persist without leading to grave organic changes, as far as clinical examination goes, though the liver or spleen, or both these organs, may become temporarily or permanently enlarged. Occasionally there are exacerbations of the jaundice or other symptoms, sometimes accompanied by pyrexia. Occlusion of one or more of the smaller hepatic ducts by a process of obliterative cholangitis is suggested by Dr. Weber as a possible explanation of the clinical features of these cases. In a case like the present one, however, it is almost impossible absolutely to exclude the presence of an atrophic form of cirrhosis.

A CASE OF TABES DORSALIS.

Dr. LEONARD S. DUDGEON showed a man, æt. 44, the chief points of interest in whom are as follows:— (1) A Charcot's foot. There is a hard bony swelling on the dorsum of the right foot due to involvement of the astragalus and scaphoid bones. The ankle-joint is quite free. (2) Atrophy of the small muscles of the right hand, especially those of the hypothenar eminence and the interossei.

PNEUMOTHORAX IN A CHILD.

Dr. H. PERCY KIDD showed a male infant, æt. 1 year 11 months, admitted to London Hospital on September 22nd, 1902, with a history of cough, wasting, and refusing food for two weeks. On admission he presented all the signs of right pneumothorax. Sputum offensive; no tubercle bacilli found. Irregular pyrexia. During October the signs of pneumothorax gradually disappeared, the breath-sounds returned, and crepitations were heard over right lung. In November a localised empyema forward was opened at the right base. Pus foul, cultures grew micrococci. In January the wound healed, and the child gradually gained weight.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD JANUARY 21ST, 1903.

Sir THOMAS FRASER, President, in the Chair.

Mr. ALEXIS THOMSON showed a man, æt. 40, in whom an ununited fracture of the tibia and fibula, unsuccessfully treated by wiring five months after the receipt of the injury, was induced to unite by means of a rigid metal plate screwed to the ends of the bone. After the wiring, which was most thoroughly done, the patient was temporarily lost sight of, and when seen again had very bad union and was obliged to wear leg-irons. The brass plate remained embedded in the tissues for five months, at the end of which time a sinus from which sterile pus exuded, developed. The plate and screws were therefore removed, the bones being found firmly united. One of the three screws used was greatly eroded; why this should have been so was not clear.

Dr. NORMAN WALKER showed "A Case of Rodent Ulcer" in a woman, æt. 45, treated by X-rays. She had an extensive ulcerated surface invading the left breast, with hard everted edges; the duration was two years. The diagnosis lay in some doubt between rodent ulcer and carcinoma, the fact that there was an enlarged gland in the axilla favouring the latter. She had been treated by exposure to the X-rays from a hard tube for seventy-five minutes in all, each sitting lasting about five minutes. As a result the immobility was lessened, the edges smaller, and the fœtor less.

Mr. STILES showed a case of "Extroversion of the Bladder," which will be found under "Clinical Records."

Mr. STILES also showed a case of diffuse nœvoplipomatosis of the right buttock and thigh.

Mr. C. W. CATHCART showed a patient after operation for "suppuration of the frontal sinuses." The onset had been very acute, and was followed by spontaneous rupture at several places. Suppuration had lasted for

two and a half years, and was cured by complete removal of the whole anterior wall of the sinuses.

Dr. LOGAN TURNER demonstrated a modification of the laryngoscope adapted for teaching. The instrument had been introduced in Vienna, and consisted of an ordinary head mirror with a square plane reflector hinged to its margin. It could be so arranged that the students, passing behind the patient, saw the laryngeal image reflected in this mirror, instead of, as usual, having to look over the examiner's shoulder at the throat mirror. (2) An anatomical preparation of the larynx preserved by Littlejohn's dry method, adapted for class teaching.

Mr. ALEXIS THOMSON showed a large carcinomatous kidney, removed from a male, æt. 30, by the retro-peritoneal route.

Dr. CHALMERS WATSON showed (1) Cast of enlarged gland from a case of exophthalmic goitre to show enlargement of the middle lobe—the lower termination of the thyro-lingual duct. (2) Photographs of the intestine of a dog to show a rare form of intestinal obstruction. Intermittent symptoms of obstruction had been observed during life, and relieved by treatment. (3) Microscopic specimens of the above, showing localised hypertrophy of the muscular coat of the ileum.

The PRESIDENT (Sir T. R. Fraser) read a paper on "THE INEFFICACY OF DISODIC-METHYL-ARSENATE."

In a previous communication he had already demonstrated the therapeutic uselessness of the cacodylates (methyl-arsenates), and pointed out that this was in entire harmony with what was known as to their pharmacological actions, which showed that they in no way acted as do the other compounds of arsenic commonly employed in medicine. Their undoubted disadvantages as regards their effects on the stomach have led some of their most ardent advocates to give up their use, and as a substitute the disodic-methyl-arsenate, to which the name of arrhénal was given, had been introduced. It is claimed to have none of the inconvenient effects ascribed to the cacodylates, to be nearly inoffensive to man and the lower animals, but at the same time to be endowed with remarkable therapeutic properties. As in the case of the cacodylates, it has been recommended as a remedy which should replace the older medicinal compounds of arsenic. It is a colourless soluble salt, which may be administered by the mouth or subcutaneously in doses of from $\frac{1}{4}$ to 3 grs. It has been used in much the same diseases as the cacodylates—all forms of anæmia, pseudo-leukæmia, leukæmia, chorea, the vomiting of pregnancy and malaria, in the last of which it has been claimed as a specific, but already Laveran has lent the weight of his authority in protest against its use as superseding quinine in this disease. The speaker had tried the remedy in several cases, of which he quoted two:—

(1) A woman with chronic eczema of two months' duration was treated by local remedies only from April 20th to May 26th without benefit. Arrhénal was begun on May 27th in doses of 1 gr. twice a day, increasing until 9 grs. were taken in the day. The drug was continued until July 19th, when it was stopped, as not the slightest toxic or therapeutic result had accrued. In all, the equivalent in arsenic of 2,000 minims of Fowler's solution were given, and on each day on which she had taken 9 grs. she had taken enough arsenic (3 grs.) to kill two adults. The second case was one of severe chorea of a month's duration. From May 15th to 27th no treatment was adopted, on May 28th arrhénal was given in the same doses as in the preceding case, and continued till June 17th. Thereafter (there being no improvement whatever) salicylate of soda and bromides were given on June 21st, and as these failed the usual rapid improvement set in whenever liquor arsenicalis was given. Pursuing a similar line of research to that employed in the case of the cacodylates, the urine of the second case was examined daily. The arsenic in the disodic-methyl-arsenate is so firmly united to the other molecules that it does not give the usual reaction with Marsh's test until it has

been oxidized with mineral acids. The formulæ of the two bodies is represented graphically thus:—

one of the molecules of CH_3 being replaced in the case of the disodic-methyl-arsenate by a molecule of NaO .

The urine of the patient gave a negative result on Marshing until it was oxidized by Gautier's process, when a copious sublimate appeared. Three days after the administration was stopped there was still an abundant sublimate, but by the sixth day elimination seemed to be complete. There was thus evidence that these enormous doses of arsenic were passed unaltered through the body, on account of the great stability of the compounds, and there was no reason at all to suppose that they had any therapeutic effect whatever.

Mr. F. M. CAIRD read a paper on "Excision of the Rectum and the Treatment of Inoperable Carcinoma of the Sigmoid," which will be found on page 82.

Dr. R. A. FLEMING read a paper on "Retinal Hæmorrhages as a Diagnostic Feature in Fracture of the Base of the Skull and in Subarachnoid Hæmorrhage." After referring to the stricture of the optic nerve, papilla, and retina, he drew special attention to the subarachnoid space, the sinus subaracnoidea basalis, and the continuation of the arachnoid into the sheaths of the optic nerves. He pointed out that the sinus basalis was a relatively large subarachnoid cistern, and that there was no median raphé, excepting the stalk of the pituitary body, which must act as a barrier in the anterior part of the space. He had found from post-mortems that when there was a sudden extravasation into the subarachnoid, the optic nerve sheaths contained blood, and retinal hæmorrhages were present, and, further, that in a number of cases of unilateral subarachnoid hæmorrhage, the retinal hæmorrhages were present only or, at least, much more markedly, on the affected side. In twelve cases of fracture of the skull, eleven of which involved the base, five cases showed after death marked subarachnoid hæmorrhage on one side of the brain and retinal hæmorrhage limited to the affected side. In two cases the subarachnoid hæmorrhage was bilateral, and the retinal hæmorrhages were more numerous and present in both eyes. In the other five cases, although there was fracture of the base, there had been on the whole less marked subarachnoid hæmorrhage, and no retinal hæmorrhages were found. Meningitis was present in two of these, and life has been more prolonged in them, with one exception, than in the previous seven cases. The exceptional case was one of very extensive fracture and enormous extravasation of blood posteriorly, with great laceration of the temporo-sphenoidal lobes, and the intra-sheath spaces had been occluded, probably from pressure on the optic nerves distal to the chiasma. Dr. Fleming referred lastly to four instances of subarachnoid hæmorrhage due to disease. Three of these were hæmorrhages in the neighbourhood of the internal capsule, which had ruptured externally or internally into the lateral ventricles. In two of these there was more marked subarachnoid hæmorrhage on one side, and retinal hæmorrhages in the corresponding eye, while in the other case the effusion was less marked, consisting principally of blood-stained serum, and there was no retinal hæmorrhage at all. In the last of this group of four cases there had been a positive hæmorrhage, which had ruptured externally, and there were bilateral retinal hæmorrhages. Dr. Fleming illustrated his paper with a number of lantern slides and a microscopic demonstration.

The paper was discussed by Mr. Miles, Dr. Chalmers Watson, Dr. Harvey Littlejohn, Dr. Paterson, and Dr. Geo. Mackay.

It has been arranged that the twenty first Congress and Exhibition of the Sanitary Institute will be held at Bradford, commencing July 7th.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD JANUARY 15TH, 1903.

RUSHTON PARKER, Esq., President, in the Chair.

Dr. W. B. WARRINGTON described a case of acute ascending paralysis, usually named after Landry. There was a distinct history of an attack of influenza about a fortnight before the onset of symptoms. Motor paralysis rapidly developed in the lower limbs and spread to the arms, face, palate, and thorax. After a stationary period of a fortnight recovery began, and became complete. Diaphoretics and morphia were given at first, then ergot, and finally, iodide of potassium and mercury. The electrical reactions were throughout normal, and the integrity of the sphincters maintained.

Dr. BLAIR BELL thought the case was one of post-influenzal neuritis. He narrated a case of true Landry's palsy he had lately seen in a girl, æt. 20. A negative neurological examination had been made by Dr. Aldren Turner.

Dr. CARTER said he had seen two cases of acute ascending paralysis in which the administration of large doses of ergot had done much good, the patients ultimately recovering.

Drs. T. R. GLYNN, A. S. GRUNBAUM, NATHAN RAW, and BUCHANAN spoke, and Dr. WARRINGTON replied.

Dr. WARRINGTON also described a case of acute yellow atrophy in a young woman who had been nursing a child for sixteen months. The early symptoms were nausea and vomiting, followed by marked jaundice and diminished liver dulness. Urea was diminished, but leucin and tyrosin were not present in the urine. The knee-jerks disappeared and the patient died from respiratory failure. Duration of illness about six weeks.

Dr. BRADSHAW said the absence of leucin and tyrosin was no presumption against the diagnosis of acute yellow atrophy; they were absent in a typical case of his own.

Dr. R. T. M. BUCHANAN showed a case of aneurysmal varix between the left subclavian artery, and the division of the left innominate vein, due to gunshot wound received in the late Boer war. Associated with the varix was left brachial monoplegia with the peculiar condition of flexibilitas cerea of the arm. Dr. Buchanan considered that some indirect damage had been done to the nerves supplying the rhomboids and the lower part of the trapezius, although the bulk of the palsy might be functional. Dr. Buchanan thought hypnotic suggestions likely to be of value.

Dr. BRADSHAW agreed with the diagnosis of aneurysmal varix. He thought the palsy entirely functional, and the wasting due simply to disuse, as there was no deformity and no atrophic change in the skin. Flexibilitas cerea in one limb was rare, but the hysterical state on which it depended was not very infrequent in soldiers who had been wounded.

Dr. BUCHANAN replied.

Dr. E. T. DAVIES related a case in which he had removed 1,754 stones from the gall-bladder of a woman, æt. 51. There was no definite history of jaundice, but the urine was coloured, and the skin tawny. The patient made an excellent recovery.

The adjourned discussion upon Dr. PETER DAVIDSON'S paper on "Infantile Scurvy" was opened by Mr. S. KELLETT SMITH, who said we were handicapped from the outset by our ignorance of the true cause of scurvy. There were many theories, but in this country we regarded the disease as the outcome, direct or indirect, of some malnutrition. In the case of adults the antiscorbutic properties of lime-juice, which contained certain known salts was amply proved, but it was false argument to conclude from this that the absence of these same salts from the diet was the cause of scurvy. Close examination of the dietary in most cases of scurvy revealed the fact that fats were present in insufficient quantity. Bottle-fed babies were especially liable to suffer in this way, for while attention was given to modification of the proteids and sugar of cow's milk,

little regard was had, as a rule, to the equalisation of the fatty matter. He thought, therefore, that in all cases showing early symptoms of scurvy the diet should be carefully criticised with respect to the proportion of fat present.

Dr. GLYNN said he had seen scurvy arise in people who had been put on a strict diet for flatulent dyspepsia. He thought some brands of Swiss milk were quite suitable for infant feeding up to seven months.

Dr. O'FLAHERTY had found it difficult to get a good mixture with added cream; butter or cod-liver oil were better. The cream might be given separately however.

Drs. RAW, BUCHANAN, GRUNBAUM, W. B. BENNETT and LEWELLYN MORGAN spoke, and Dr. P. DAVIDSON, in reply, said that although the cases were still rare, yet the disease was on the increase, apparently from the increased use of preserved milks. In his experience there was no artificial food that could equal fresh cow's milk suitably modified.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 25th, 1903.

COMPULSORY NOTIFICATION.

At the meeting of the Académie de Médecine, M. Josias read a report on the maladies for which notification was considered to be obligatory, and said that he would propose adding to the list already drawn up by the Academy two other affections—measles and cerebro-spinal meningitis when they existed in the epidemic form. On the other hand, as there existed a certain group of contagious affections which for divers reasons the obligatory declaration was not practical, he proposed to draw up a list of affections of which notification would be optional, and which would comprise phthisis, whooping-cough, influenza, pneumonia, erysipelas, mumps, leprosy, and purulent ophthalmia in the adult.

After some remarks by one or two members, the president put to the vote the report, and the following list of maladies was adopted as requiring notification: Typhoid fever, typhus fever, chicken-pox, scarlatina, measles, diphtheria, cholera, plague, yellow fever, dysentery, puerperal fever, ophthalmia of infants, and cerebro-spinal meningitis when epidemic.

The affections placed under the head of optional notification were those proposed by M. Josias and already given in these columns.

THE TREATMENT OF ECLAMPSIA.

Professor Maygrier, speaking on eclampsia, said that formerly that affection was considered as a nevrose, but to-day it is more rightly known as an auto-intoxication of the organism.

The first symptom being frequently albuminuria, it was necessary to place on milk diet every pregnant woman whose urine was albuminous, and enjoin rest in bed. The régime continued eight days placed the patient beyond the reach of the malady. Once eclampsia declared, the first thing to be done was to remove from the organism the toxic principles and to calm the nervous excitability. The first indication was filled by blood-letting—from ten to twelve ounces should be taken as rapidly as possible. He was in the habit of injecting immediately afterwards, hypodermically, an equivalent amount of artificial serum.

The agitation and excitability were best controlled by a few whiffs of chloroform and an enema of chloral. The Germans recommended morphia, but it should be used with caution.

Several authorities advised emptying the uterus with all possible celerity, but such was not his opinion, as the eclampsia could persist after delivery, and on the other

hand the pregnancy could continue after the attack. Only two complications could warrant intervention: anuria or a rise in the temperature. Beyond those conditions the pregnancy should not be interrupted. But, on the other hand, if the labour had already set in, every means should be employed to deliver the mother as quickly as possible, forceps, version or extraction, as the case might be.

CARDIAC COLLAPSE.

Citrate of caffeine .. 0.75 centigr.
Chloride of sodium .. 2.50 "
Distilled water .. 500 grammes.

Dr. Morfan, who recommends this serum in cardiac collapses, injects 50 cubic centimetres, and renews the injection if necessary.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 24th, 1903.

At the Society für Innere Medizin, Hr. Weber showed a preparation of

BONE IMPACTED IN A BRONCHUS.

The preparation consisted of the right lung of a young man in whom gangrene of the middle lobe of the lung had followed impaction of a piece of bone in the bronchus. After swallowing the piece of bone at the end of March, 1902, he had been attacked with violent lung troubles, which gradually improved, leaving only a dull feeling of oppression behind. In the hospital no objective cause for this sensation could be made out. There was no fever; auscultation and percussion revealed nothing abnormal, neither did radiography. It was concluded that the patient had really swallowed a small splinter of bone, and that he had later on coughed it up, and that the symptoms complained of were only a consequence of the irritation then set up. On October 7th, however, he returned with very serious symptoms. He was very much reduced, there were fever and cough with fetid expectoration. There were tympanitic dullness over the right lung, amphoric breathing, and râles, especially marked over the second rib. It was assumed that an abscess was located at the spot; operation gave no relief, however, and the patient died. The autopsy showed that a piece of bone, larger than the thumb-nail, lay in the main bronchus of the right lung and had set up gangrene. It was remarkable how few subjective symptoms had been caused by the accident. The localisation of the disease was also of interest. One would have thought that the inflammation would have been worst nearest the site of the foreign body and would have spread downwards from it. But here the course was the opposite of this; in opposition to the laws of gravity it had extended upwards.

Hr. Stadelmann reported that three years ago a patient had been admitted into hospital. There was extensive empyema on the right lung that was operated on, and contained fetid pus. The patient died. In a bronchus autopsy revealed a large piece of bone that had been swallowed six years before. At the site of the impaction there was inflammation, from which metastasis had originated, whereby the empyema was set up, from which the patient died.

Hr. A. Fraenkel remarked that such cases could be helped by aid of a bronchoscope. In many cases the foreign body could be seen and not seldom extracted. The extension upwards was explained by the gangrenous spot.

Hr. v. Leyden recalled two particularly interesting cases of the kind, both in medical men. One case was

that of a military surgeon who for years was ill with cough and putrid sputum; the disease was thought to be tuberculous. The patient died and a piece of bone was found in one lung. In the second case also the patient was ill for years with cough and putrid expectoration. One day, after a violent attack of coughing with retching, he brought up a shirt button. He recovered. In neither case was anything known etiologically.

Hr. Grawitz had unknowingly brought a preparation of a similar kind for demonstration. A young girl had sprung into the water a year before to save a man. Since that time she had been ill with cough, had pain in the right side of the chest, and râles could be heard. Then remitting fever set in and a streptococcal empyema developed. It was supposed that the disease arose from a chill caught from jumping into the water. Then came a letter from a former master of the girl saying that a long time before she had swallowed a shirt button that she had in her mouth when a cough came on. No shadow of a foreign body was shown, however, by radiography. An operation for empyema was performed, but the patient died. At the autopsy a shirt button was found in the right bronchus, no gangrene of the lung, but only diffuse bronchitis. If the diagnosis had been certain, the patient might have been saved by inferior bronchotomy and removal of the foreign body.

Hr. Borchardt related the following case:—A child *æt.* 2, had a cavity in the right lung. Radiography showed a feather. He resected several ribs posteriorly but could not find the feather. Inferior tracheotomy was now performed, and he succeeded in removing the feather, that had been in the bronchus for nine months, by aid of a pair of forceps. Bronchoscopy had been tried and failed. The little patient lived seven months and then died of a tuberculous affection.

At the Medical Society a discussion took place on Hr. Liebreich's

NOTE ON BORAX AND BORACIC ACID.

Hr. Mankiewicz said that after giving large doses of borax, he had seen eczema of the toes and fingers with loss of the nails. This occurred every time one patient took large doses of borax. He then described the acute borism that workers in borax factories suffered from.

Hr. Menchel had given 0.5 gramme of borax daily for long periods to epileptics and had never seen harm resulting from it.

Hr. Liebreich remarked on the great difference between giving 100 grammes of borax in a short time and taking flesh preserved in it, which would contain at most 0.1 to 0.3 per cent. If there was more than that the taste would be spoilt. He further emphasised the fact that death had never been known after borax, whilst an undoubted case of death was known from excessive use of salt. No one, however, would give up the use of salt for this reason. The great advantage of boric acid was that it only preserved fresh meat; putrid meat in spite of it still retains its nasty taste. Flesh preserved with borax might be designated as such, but it was unjust to do away with borax as a preservative agent altogether.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 24th, 1903

TOXIC AND AUTOTOXIC DERMATOSES.

At the *Doktoren Kollegium*, Ehrmann read a paper on "Toxic and Autotoxic Conditions of the System Arising from the Cutaneous Application and the

Internal Administration of Drugs." Prior to, and even during, Hebra's time, the teachings of humoral pathology acknowledged the toxic effect of external agents, although it was universally admitted that all dermatoses were the outward expression of a humoral disturbance. However theoretical this opinion may appear, after long experience and close observation, a few grains of truth are still left in the dogma.

We now know definitely that there are noxious substances in the blood and fluids of the body that give rise to skin eruptions, probably not directly, but through the agency of the nervous system. Physiological experiments demonstrate clearly to us that irritation of one nerve will cause hyperæmia, while irritation of another will cause anæmia, showing that we may have both centripetal and centrifugal reflex action on the vessels. An internal toxic agent, such as quinine or copaiba balsam, acting directly on the nervous system, will produce cutaneous manifestations. Again, the internal application of an irritant may act on the central nervous system, leading to over-stimulation of the cell protoplasm and so producing proliferation of cells. This theory has been demonstrated in many cases, and assumed in others in explanation of many cutaneous diseases.

The autotoxic form of dermatosis may be illustrated in the practice of inunction, where the application of mercury produces a scarlatinial erythema and a few days later a typical eczema, with tumefaction of the mucous membrane. Turpentine is another agent which when used externally or internally, produces an eczematous erythema.

Jadassohn has published observations of eczema due to calomel poisoning, and the use of antipyrin is not free from this drawback. The latter has two forms in which it appears, first as a universal scarlatinial rash followed by bullæ and subsequently ending in a pemphigoid desquamation; the second form is a localised fixed erythema occurring on the tongue, mouth, and conjunctive, and often associated with vesicular eczema and dark grey pigmentation. It occurs more frequently in females than males. The sera afford another source of eruption due to toxic action. After the injection of anti-diphtheritic serum an intense erythema is sometimes produced. Vaccine is another fruitful source, while injections of tuberculin produce an exanthema well known to all.

Autotoxin arising from the bowel produces a form of pruritus not uncommonly associated with constipation. Ehrmann related a case of constipation due to stenosis that came under his personal observation. The patient suffered intensely from a form of dermatitis, which entirely disappeared after an operation had been performed for the stricture. Another fruitful cause of erythema is helminthiasis, which resembles the antipyrin exanthem due, probably, to the poison of the worm and not the result of nervous reflex action. Sclerodermic urticaria is the result of another autotoxic poison commencing with erythema and defying all local treatment. Polydypsia, oliguria, œdema of the extremities, and bronchial catarrh are a few of the results arising from autotoxic substances. Arsenical hyperkeratosis often attacks paper-hangers, while other forms of arsenical dermatosis are the result of hyperhidrosis of the extremities, particularly between the toes, producing first of all a form of erythematous eczema, culminating in chronic thickening.

In the discussion that followed, Nobel suggested that many of the author's remarks would be better explained by idiosyncrasy on the part of the patient. It is not uncommon for such drugs as arsenic to produce disturbances of the alimentary canal which might give rise to all the phenomena he had described.

NORTH-WEST LONDON HOSPITAL.

RESECTION OF THE ULNA NERVE AFTER BEING DIVIDED FOR SIX MONTHS.—Mr. MAYO COLLIER operated on a young man, *æt.* 20, for paralysis and loss of sensation of the muscles and skin on the inner side of the hand and arm such as would follow complete division of the ulna nerve in the middle of the arm. Six months previously the youth had fallen through a window and had inflicted on himself a long jagged wound on the inner side of the left forearm extending upwards and outwards dividing the two inner tendons of the flexor sublimis, part of the flexor carpi ulnaris, the palmaris longus with the ulna artery and nerve. The wound had apparently been skilfully attended to so far as the muscles and artery were concerned, but the more or less common mistake was made in neglecting to search for and find the divided nerve. The consequences of this omission were only too soon realised by paralysis and loss of sensation of the muscles moving the little and ring fingers and weakness of the hand generally. The arm was painful, and some thickening could be felt in the site of the old scar. This was clearly a case for attempted resection of the nerve. After depriving the limb of its blood with an Esmarch's bandage Mr. Collier made a long incision in the line of the nerve from a little above the wrist to the upper third of the arm. The intermuscular septum between the flexor ulnaris and sublimis was hit upon and the nerve found with ease. The upper end was much retracted and clubbed, and adherent to the scar. The lower end had drifted to the inner side of the arm and lay under the flexor carpi ulnaris and was adherent to the scar tissue covering the bone. Allowing for the necessary loss in paring the nerve before suturing, the distance between the cut ends, Mr. Collier remarked, would be a serious difficulty in attempting to join them. This difficulty was overcome by continued gentle traction of both ends. A fine silk thread was run in and out through the nerves so as to effect a good hold, such as is done in tendon suturing. By these means the cut ends were closely approximated and the wound closed. The wrist and arm were flexed and the patient sent to bed. Mr. Collier said the difficulties of this case were increased by the distance separating the cut ends. This had been overcome, and a good result might be hoped for.

ROYAL LANCASTER INFIRMARY.

COMPLICATED CASE OF SCROTAL HERNIA.—Mr. STANLEY BARLING operated on a complicated case of scrotal hernia in a man, *æt.* 56. The patient was sent to him from a distance with the following history: Four days previously his medical attendant had tapped the tumour and drawn off two and a half pints of clear fluid. In a short time acute symptoms made their appearance. The scrotum rapidly enlarged, and became very painful. This was accompanied by sickness and fever, the temperature rising to 103° F. On admission the scrotum was found to be distended by a tumour almost as large as an adult head, which extended up into the inguinal canal. The penis was completely buried. There was no feeling of fluctuation, no impulse on coughing, and the percussion note was dull. Under ether a long incision was made over the length of the tumour. On opening the sac a great mass of sloughing omentum was exposed. This, weighing 5½ lbs., was removed. Gangrenous colon lay behind it, the coils all matted together, and also adherent to a knuckle of ileum. On the outer and posterior side of this was an abscess cavity containing about half a pint of foetid pus

intermingled with fæces and communicating by a hole, which admitted the index finger, with the interior of the large intestine. About 18 ins. of the ascending colon, the cæcum, and 9 ins. of the ileum were then excised, and end-to-end anastomosis performed with two continuous sutures. A quarter of a grain of strychnine was given hypodermically, and six pints of saline solution introduced into the veins of the left arm. Mr. Barling remarked that the hydrocele trochar had evidently entered a sac distended with ascitic fluid and had unfortunately also perforated the intestine.

The patient, who had been *in extremis*, rallied well. Five days afterwards there was some leaking of fæcal matter from the upper end of the wound, but this soon ceased and he made a complete recovery.

The Out-Patient Departments.

TOTTENHAM HOSPITAL.

CASES FROM THE DERMATOLOGICAL CLINIC,
UNDER THE CARE OF G. NORMAN MEACHEN, M.D.,
M.R.C.P. LOND. AND EDIN.

1. *Recurrent Herpes of the Face.*—A boy, *æt.* 13, came with a vesicular eruption around the left orbit which appeared two days previously, preceded by pain in the left side of the head. He said he had had the same kind of "breaking out" every year since he was five years old, when he had a "bone scraped" on his forehead. There was a typical herpes involving the left malar bone and extending along the infra-orbital margin towards the nasal bone. There was a small horizontal linear scar upon the left frontal eminence. The conjunctiva was normal. Dr. Meachen said that these cases of recurrent herpes of the face, which had been so well described by Bertholle, were most interesting. The left side of the face was more often affected and some degree of migraine was invariably present or preceded the outbreak by a day or two. It used to be a favourite observation of Bazin that migraine was a symptom seen specially in those of an arthritic or a herpetic diathesis. Other forms of recurrent herpes affecting the labial margins were more common, and usually resulted from a chill or a slight gastric catarrh. Whenever the bodily resistance was lowered an eruption of herpes was apt to occur in predisposed individuals. The eruption in this boy could not be called an "ophthalmic zoster," as the herpetic rash in that complaint was higher up, involving the supra-orbital margin and the external canthus. Moreover, ocular complications were prone to occur, some of them serious, such as iritis, whereas in this case the eye was unaffected. Neither could the lesions be mistaken for erysipelas, for the individual vesicles were small and closely aggregated, with a separate zone of erythema round each. Oedema was absent. An astringent dusting-powder of bismuth subnitrate, boric acid and starch was ordered for external application, and 1½ grs. of quinine sulphate in a mixture thrice daily.

2. *Sycosis of Syphilitic Origin.*—A clean-shaven coachman, *æt.* 52, presented himself with a "sore lip" which he had had for three weeks. There was no itching. On examination, the upper lip was swollen, lumpy, and glazed in parts, especially at each corner. From these areas, which felt thickened and infiltrated and which encroached upon the labial margin, a few hairs were growing, but they could be pulled out whole, and on microscopic examination no spores were seen. Crusting and pus-formation were conspicuous by their absence. The beard-region was unaffected. Dr. Meachen remarked that the confinement of the lesion

rigidly to the upper lip was, in itself, almost sufficient to exclude tinea, though he confessed that the smooth, glazed, lumpy condition strongly resembled a parasitic sycosis, but ringworm of the moustache-region alone was uncommon. Moreover, the peculiar infiltration should make one suspect a specific origin in this case. Coccigenic sycosis could be excluded from the absence of pustular lesions.

On further examining the patient, a patch of dull red papular infiltration, the size of a half-crown, was seen on the inner side of the left upper arm, and another similar one on the right shoulder. These he had not mentioned as he thought them to be of no importance. Five years previously, about one month after acknowledged exposure to infection, he suffered from sore throat and an "ulcerated" mouth, with loss of hair, and was under treatment for four months. Dr. Meachen insisted upon the importance here, as in all cases, of inspecting whenever possible the whole skin, as frequently some light is thereby thrown upon an obscure case, or a suspected diagnosis is confirmed by the discovery of other, and perhaps more typical, lesions which the patient himself may consider of no consequence or of the existence of which he may even be unaware. This man was given gr. v. of pot. iod. with dr. j. of the liq. hydrarg. perchlor. in a mixture thrice daily, together with a weak ammoniated mercury ointment for the lips and arms. Under this treatment the infiltration speedily resolved, and in a month's time it had practically disappeared.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25 Os. 0d.; Half Page, 12 10s. 0d.; Quarter Page, 6 1s. 0d.; One-eighth, 1s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 22s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books &c.—Seven lines or under (70 words), 4s. 6d. per insertion 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 28, 1903.

CORONERS AND POST-MORTEM EXAMINATIONS.

THE necessity of united action and of a good representative administration has long been recognised by members of the medical profession. The latter find themselves helpless against the inroads of unqualified practice, no less than of ill-regulated philanthropy and of highly organised bodies, both public and private, seeking to exploit the services of duly qualified practitioners. The latest attempt to deprive the medical profession of one of its few emoluments remaining comes from the London County Council. In

many instances the work of that body has been excellent, but, in our opinion, for reasons that follow, the present attempt to foist an official public pathologist upon the community appears to be unwise in its conception, illegal in its imposition or attempted imposition, and absolutely unjust to the medical profession. The facts of the case are familiar, and should be borne in mind by every medical man in the United Kingdom, for experience has long shown that the experiment of London to-day will be the experiment of the provinces to-morrow. Briefly, the Council have made a sort of semi-official appointment of Dr. Freyberger as Public Pathologist. It is difficult exactly to describe the position of the gentleman in question, for the chairman of the London County Council has publicly declared no such appointment has been made, but his utterances on the point were somewhat confused and unsatisfactory, and, weeks after his denial, Dr. Freyberger is still described as appearing at inquests in the rôle of County Council Pathologist. Whatever may be the precise verbal loophole through which the chairman found it convenient to wriggle, we take it there can be no reasonable doubt that Dr. Freyberger was recognised by the Council as the proper person to perform any or all of the post-mortem examinations required by the coroners appointed by the Council, at a fee of two guineas per case. The upshot of the Council's deliberations was to resolve: "That all coroners be informed that in the opinion of the Council it is desirable that post-mortem examinations in inquest cases of a special nature should be entrusted to a specially skilled pathologist." In the beginning of July, 1902, Mr. Troutbeck was appointed by the Council as coroner for the South-Western District of London. Before being appointed he agreed to carry into effect the above resolution. This he has since attempted to do, but his action has roused general indignation among the practitioners of the district. In the first place, Mr. Troutbeck seems to have acted unwisely in submitting to pressure from the Council to carry out an arrangement which appears to be distinctly illegal. It is difficult to understand what are the special qualifications possessed by Dr. Freyberger over those of the average general practitioner in the performance of an everyday post-mortem examination. If the ordinary medical man is unable to carry out a simple investigation, then the system of high standard modern medical education must be stamped at once as a miserable failure. As to "cases of special difficulty," which, it is to be presumed, allude chiefly to poisoning, no claim has ever been made by general practitioners that they should carry out such highly expert investigations. Mr. Troutbeck desired Dr. Freyberger to perform a second examination in a case already examined by the hospital pathologists. An action of that kind is calculated to bring the coroner into direct conflict with the medical profession both in its public and its private capacities. By insisting on the employment of a public pathologist in the making of ordinary post-mortem examinations the County

Council will be inflicting both a moral and a monetary injury upon the medical profession. It is to be hoped that they will be wise enough to reconsider their attitude with regard to this matter before further mischief is done. We are surprised to note that such a proposal was allowed to pass the Council without a vigorous protest from the medical men who are members of that body. It is to be hoped that the future action of the Council on this important question will be swayed by a carefully-considered report drawn up by Sir W. J. Collins and other medical councilors in conjunction with some trustworthy outside members of the profession, who will be really representative of the general practitioners as well as the hospitals.

ON THE TRANSFERENCE OF BOVINE TUBERCULOSIS TO MAN.

SINCE the epoch-making discovery of Koch in 1882 of the tubercle bacillus, progress in regard to matters tuberculous has proved so rapid that dangers, difficulties, and differences have arisen from the impossibility of adequately verifying the statements of the various investigators. And thus confusion and conflict were inevitable. The startling pronouncement of Koch at the London Congress, setting aside any consideration as to the correctness, or otherwise, of his contention, has proved of incalculable benefit, in that it has, as it were, called a halt in the undisciplined and, in some ways, misdirected energy of many unscientific enthusiasts; and has not only stimulated all civilised nations to undertake more scientifically-conducted research, but has also made necessary a thorough effort to "verify references," many of which have been manifestly misleading. It will doubtless be some time before anything like certainty can be arrived at regarding the transference of bovine tuberculosis to man. Meanwhile, it is interesting to note that Professor Koch, as judged by his address at the recent International Conference on Tuberculosis in Berlin, still strongly holds to his view that the milk of cows and the flesh of animals suffering from *Perlsucht*, must not be considered as in any way a common or serious cause of tuberculosis in the human subject. And it must be admitted that the facts and arguments presented are undoubtedly weighty and deserving of the most careful consideration. Efforts have been made throughout Prussia to obtain trustworthy information respecting cases of primary intestinal tuberculosis, where the disease was ostensibly caused by milk from cows suffering from *Perlsucht*, but Koch has, during the last year and a quarter, been unable to find any such example. It is, of course, well known that veterinary surgeons, pathologists, butchers, and slaughterhouse employees not infrequently develop the so-called tuberculous verrucosa cutis. But Koch considers that no well established case exists where general tuberculosis could be considered to have developed from such a local infection. Baumgarten's communication concerning cancer patients inoculated with virulent *Perlsucht* bacilli

strongly substantiates Koch's contention. Koch, moreover, holds that even the occurrence of *Perlsucht* infection, which remains local, as a result of a skin wound, does not in any way prove that *Perlsucht* bacilli are also in a position to infect the uninjured intestinal mucous membrane, or that they are able to pass through it without leaving any traces behind. Koch shows that where infective disease arises from contaminated milk or diseased flesh cases are met with in groups and often in epidemics and not as isolated illnesses, and he holds that a tuberculous infection must also take shape in the same way if tubercle bacilli, which are virulent for man, are found in meat and milk. It is interesting to note that Fraenkel even before the discovery of the tubercle bacillus, maintained the opinion that tuberculosis could not be conveyed by the milk of cows suffering from *Perlsucht*, because several children in the same family practically never suffered at the same time from tuberculosis as would have been the case if the common milk-can furnished the cause. Koch has devoted much attention to an investigation of cases said to have originated from tuberculous meat, but finds that "proof of the danger of meat infected with *Perlsucht* is completely wanting." And yet "no one will contest that the *Perlsucht* bacilli in meat are identical with those occurring in milk, and an insoluble contradiction exists in the fact that far stricter views have prevailed recently against the milk of tuberculous beasts than against tuberculous meat." Koch also draws attention to the inconsistency of those who while boiling their milk take no precaution to ensure the safeguarding of the products which are made from it, especially butter, which very frequently contains living *Perlsucht* bacilli. We are unable to follow Dr. Koch through all his careful analysis of long-recorded cases which have hitherto been supposed to afford trustworthy evidence of the transmission of tuberculosis from animals to man, but it must be admitted that his latest researches go far to strengthen his position. Meanwhile, we await the report of our own Government inquiry into this matter, and trust that a preliminary report will be forthcoming as soon as thoroughly trustworthy conclusions have been arrived at.

THE EDUCATION OF WOMEN.

A WRITER in a recent number of the *American Journal of Obstetrics* ventures to criticise the present system of feminine education in a manner which shows he has not the reverence for the feminine educationalist which that person demands. He is one of those daring people who take leave to consider that the health of the female is of more importance to the world in general than is her education, and, though he perhaps clothes his opinions in a little too verbose a garb, he still enunciates many truths that are daily forgotten probably because the opportunity for learning them is of daily occurrence. The highest and noblest functions of the medical profession is the prevention of disease, but yet, according to our writer

that profession does not lift up its voice with sufficient definiteness to point out the innumerable fallacies upon which the present system of feminine education is based. "It is of paramount importance that our women should be healthy, for how can it be expected that they will be prolific and the mothers of a healthy progeny if they are themselves not vigorous? What does it advantage a woman to attempt to unravel the laws of physics, or to solve difficult problems in mathematics if by so doing she violates the laws of her own existence, lays the foundation for uncertain health, and renders herself unfit to be the mother of a healthy offspring." The danger to which the writer alludes is probably more urgent in America than in the British Isles, but can it be said that there is no tendency to its growth. It is, at least, probable that the higher the civilisation of a race the lower becomes its vitality, and that gradual decadence follows. The race that would remain hardy and virile must see that the parents of its children are such as can produce hardy and virile children. Fashion has much to say in these matters. Universal occupation for women is the present cry, and girls are brought up with the notion that they must earn their own bread, and that everything is subservient to the necessity for acquiring the power of so doing. In time, doubtless, the pendulum will swing back into its former position, and the world will not be disimproved thereby. The most serious aspect of its present over-swing is the danger of the production of a vicious circle from which the most able political economist will be unable to extricate us. The increased conversion of women into wage-earners diminishes seriously in many walks of life the number of wage-earning and hence of marriageable males. In consequence, a still greater number of women are converted into wage-earners, and they in turn further diminish the number of male earners. The process continues, until the population of the country becomes seriously affected or until the wife is accepted as a necessary wage-earner of the family. Either ending is bad for the race. An increasing and not a diminishing population is necessary in view of our present Colonial needs, while racial vitality is even more important than numbers, and is incompatible with the mental and physical overstrain of the women. The matter will ultimately be one for political economists, but the responsibility for directing attention to one side of the danger rests primarily on the medical profession. The question asked of each member of the profession by the writer of the article to which we have referred is a very proper one:—"Do you exercise the great influence of which you are capable in overcoming the pernicious mode of educating young girls?"

WE congratulate Dr. Clouston—as doubtless all who recognise his distinguished attainments will do—on his election to the Presidency of the Royal College of Physicians of Edinburgh. The compliment will be especially appreciated by that large contingent who are engaged in asylum work, in which Dr. Clouston has for so many years played so conspicuous a part.

Notes on Current Topics.

Pregnancy in an Undeveloped Uterine Cornu.

CASES of pregnancy in the rudimentary horn of a two-horned uterus are of rare occurrence, and cases of this condition in which the pregnancy continues to full term without rupture of the containing cornu are among the curiosities of obstetrical literature. A rudimentary cornu is to all intents and purposes a Fallopian tube, and, if quite rudimentary, will not withstand the bursting strain to which the presence of a growing ovum gives rise for a longer period than will a Fallopian tube. Still, undoubted cases of pregnancy in such a cornu have been recorded in which rupture of the sac did not take place. It is possible that this may be explained on the hypothesis that the degrees of development to which the cornu attained was greater than is usually supposed. An interesting case of continuance of pregnancy to full term without rupture of the cornu is recorded in the issue of the *Journal of Obstetrics and Gynaecology of the British Empire*, by Drs. T. R. Smith and Herbert Williamson. In their case, the ovum was situated in a large spherical tumour attached to the uterus by a pedicle in the neighbourhood of the base of the left broad ligament. The tumour was almost wholly covered by peritoneum, and the left Fallopian tube, round ligament, and ovarian ligament all terminated in its substance. The area which was uncovered by peritoneum apparently corresponded to the intra-ligamentous portion of the uterus, and, at one angle of it, a cord-like structure appeared which had been cut across during the operation. This structure was impervious, and was probably the remains of the vaginal end of the cornu. At first sight, it would appear to be difficult to account for the occurrence of impregnation if the vaginal extremity of the cornu was really impervious. It is, however, very probable that in such cases the impervious condition found at the time of operation is the result of changes in the mucous membrane, the result of pregnancy. This view also commended itself to the writers of the paper.

The Dangers of the Habit of Expectoration.

THE difficulties in the way of the reforms attempted by the National Society for the Prevention of Tuberculosis are typically exemplified by a letter which appears in one of the daily papers, *à propos* of a proposal on the part of the Great Northern Railway of Ireland to place notices forbidding spitting in their third-class compartments. The gentleman who writes the letter in question is indignant that the notice should be confined to the third-class carriages. One would at first consider that the reason for his objection was that such a notice was equally necessary in the other classes, but on reading further, the real cause is found to be that "it is as ridiculous to ask a person (who perhaps is suffering from a severe cold, or a habitual smoker) to refrain from spitting as it is to expect him to refuse to breathe." The writer of the letter, in spite of a few lapses of gram-

mar, still appears to be an educated man, a fact which makes his mental attitude all the more unsatisfactory from the point of view of the public health. How is it possible for any society to effect an improvement in the conditions which favour the propagation of phthisis, when even the tolerably educated section of the people are so ignorant of the common principles of hygiene, not to mention the necessities of decency? It is still more unfortunate that daily papers, which in one column print an editorial comment approving of the aims of the Association should, in another column, print such letters as that to which we have referred—letters which, no matter what their inherent folly, influence the minds of other people as foolish as the writer. Nothing but determination on the part of the railway companies to punish offenders will put a stop to the disgusting practice of expectoration in carriages. The Great Northern Company "request" their passengers to refrain from an obnoxious practice; a direct command would be of more value.

Group-Dementia.

THE science of ethnic psychology is based on the assertion that there is a tribal, racial or group mind as well as an individual one. It is a fact that the minds of multitudes respond simultaneously to a common impulse, often a mad one, and do deeds which the individuals of the mass, in a sane state, would not do. A curious instance of this recently happened when several hundred Russian peasants, called Doukhobors, marched through Manitoba seized with a religious mania which impelled them to set out on a journey "looking for Jesus," their leader a fanatic named John the Baptist. They left comfortable villages, turned loose their cattle, and, abjuring the use of leather or any animal product, walked barefoot during a Canadian winter. At Minnedosa the Government intercepted the march and forcibly sent them back home. An instance of tribal madness occurs in some South African tribes who are seized by a common impulse to kill all their cattle in belief that the tribal gods will it.

The Mortality of Measles.

THE popular view of measles is that it is a disease of little importance against which it is unnecessary to take ordinary precautions. Statistics show, however, that though the case mortality may be comparatively low, the mortality in the aggregate is very high. In the County of London, for instance, during the year 1900, the deaths from measles numbered 1,930, which is greatly in excess of diphtheria, which is credited with 1,500 deaths, and nearly twice as great as scarlet and typhoid fevers together, with 361 and 717 deaths respectively. With this object lesson before us it is idle to pretend that measles can safely be treated as hitherto, and we note with satisfaction that the Health Committee propose to recommend the application of certain provisions of the Public Health Act to persons and places infected therewith, notably the disinfection of clothing and premises and the

partial isolation of persons suffering from measles by forbidding their carrying on their occupation in such a manner as to convey infection, by travelling in public conveyances, &c. No other evidence is required of the backward state of public intelligence in matters sanitary than the fact that seven out of seventeen metropolitan boroughs object to this very reasonable proposal.

The Doctor as a Detective.

UNDER the heading "Strange Conduct of Silverdale Doctors," a Birmingham contemporary reports certain proceedings which took place at a local police court in connection with the attempt of a butcher's assistant to commit suicide. The prisoner had discharged several shots from a revolver at himself, but apparently without inflicting any serious injury. Mr. Noonan, who was acting as assistant to Dr. Daly, of Newcastle-under-Lyme, was called to the man, but as the wounds were not of any gravity he took no further steps, and for this reason he was sharply reprimanded by the bench, who disallowed his expenses on the ground that he had displayed great negligence. This dictum raises a question of considerable importance as to the circumstances under which a medical man is called upon to act as informant. We may premise that it is no part of a practitioner's duty to act the part of a detective unless for the purpose of preventing crime. It is not for him to inquire into the conditions under which the wound which he has to dress was inflicted, except in so far as this may be required for the purpose of treatment. In the case before us, however, it would seem that in the interest of the patient himself some precautions were necessary, and it behoved the medical man who was called in to protect the patient against further attempts by communicating with the police or otherwise. The suggestion that the practitioner is under an obligation in every case to report the fact to the police is quite inadmissible, and public opinion would certainly not support him if he did so.

A Lapsus in Hospital Administration.

SOME scandalous revelations elicited at a recent inquest in London concerning the death of an intoxicated woman direct attention to the absence of facilities for disposing of persons, intoxicated and otherwise, who, for any reason, cannot be admitted to hospital. The police persist in regarding a hospital as a private dwelling into which they will only penetrate when it suits their purpose. Advantage is but too frequently taken of this technical point to decline assistance, thus throwing a grave responsibility on the hospital staff, and not unfrequently entailing serious mischief to the patients. In the case just referred to, the police refused to remove a drunken woman from the hospital until the porter, with a brutality which long experience is apt to engender, threw the unconscious woman on to the pavement, thus bringing her within the scope of police activity. In another instance the police refused to intervene in the case of a woman who had declared her intention of

taking poison, and had actually procured the wherewithal to destroy life. The woman was consequently allowed to go her way since she was obviously not a fit subject for hospital treatment. There is no obvious reason, except the chaotic jumble of the various administrative departments, why hospital medical officers should not be empowered to requisition an ambulance for the purpose of removing such patients to the infirmary, where they can be properly looked after until suitable measures can be taken. The police constitute but an unsatisfactory agency for dealing with such cases, and possibly when the London County Council has organised an adequate ambulance department the difficulty will in part have been overcome, although even then a better understanding will have to exist between infirmaries and hospitals than at present obtains.

Transplantation of King's College Hospital.

It is stated that the governors of King's College Hospital have under consideration a scheme for the removal of the hospital to a more salubrious, or, at any rate, to a more congenial, site, the said site not being more than four miles distant from the present one. If this scheme be realised, a first step will have been taken in the direction of a much-needed readjustment of the geographical distribution of the medical charities of the metropolis.

An International Medical Manifesto in Favour of Temperance.

A MANIFESTO has been agreed upon by the medical temperance associations of Great Britain, America, Germany, and France, calling the attention of medical practitioners all over the world to the terrible evils resulting from the consumption of alcohol, concerning which it behoves medical practitioners, as guardians of the public health, to speak plainly. Special stress is laid upon the injurious action of alcohol, even in small doses, upon the intellectual functions and the impairment of self-control, and the sense of individual responsibility which results from its habitual use. It is pointed out that the habitual consumption of alcoholic beverages precipitates the retrograde changes incidental to advancing years besides increasing the liability to certain intercurrent maladies. It is stated, moreover, and the assertion has the weight of unquestionable authority, that persons who abstain from the use of alcohol possess greater physical stamina and, in addition, that they escape a whole series of diseases specially due to the noxious action of alcohol. Neurologists are agreed that alcohol disturbs the equilibrium of the nervous system, not only in those who indulge but even in their offspring, with the inevitable result of bringing about deterioration of the race, mentally, morally, and physically. No one who ponders upon the poverty, suffering, vice, crime, disease, and death, which result from the use and abuse of alcoholic beverages will be disposed to deny that a grave responsibility

rests with medical men in their attitude towards the public in respect of this all-important question. A very great change has come over medical opinion in this connection during the last few years, but it behoves medical men to preach not only by precept but by example.

The Clinical Features of Post-Diphtheritic Paralysis.

THE generally received ideas concerning clinical manifestations of post-diphtheritic paralysis convey a somewhat misleading view of these very interesting manifestations of toxic neuritis. As a rule the motor disturbances are very slight and sensory disturbance are almost unknown. The flaccid, hanging soft palate which figures in every text-book is, in reality, very rarely seen, the disturbances usually taking the form of a mild paresis of all the palatal muscles. The pharyngeal reflex is almost always intact. The paralysis of accommodation attacks the ciliary muscle and respects the iris, although at a certain stage of the disease, the contraction of the pupil for distance may be impaired, but the light reflex never fails. With regard to the extremities muscular contraction is never entirely abolished. What we find is a plastic paresis with disappearance of the tendon reflexes and integrity of the sphincters. Cardiac disturbances accompanied by vomiting are by no means uncommon, but bulbar paralysis is extremely rare. The salient features of post-diphtheritic paralysis are those of a mild neuritis not associated with sensory disturbances, sometimes of diffuse but very mild anterior poliomyelitis. Experience does not bear out the view that has been advanced more than once that injections of serum predispose to the occurrence of these nervous troubles, but, on the other hand, they cannot be said to exert any directly curative action in regard thereto. It is highly probable that the incident of these nervous troubles is in great measure dependant upon the date at which the injections are made, and on the potency of the serum. The longer the virus is left uncontrolled the more likely is the nervous system to be attacked. The view that the occurrence of post-diphtheritic paralysis is *prima facie* evidence of the continued presence of the toxin in the blood is accepted by sundry respectable authorities as an indication for the further administration of antitoxin, not on account of any directly curative action on already existing lesions but in order to neutralise the poison and so prevent further developments.

THE Eleventh International Congress of Hygiene and Demography will be held in Brussels from the September 2nd to 8th, 1903, under the patronage of H.M. the King of the Belgians. The Secretary-General of the Congress is Professor Dr. F. Putzeys. All information and programmes can be obtained from Dr. Paul F. Moline, 42, Walton Street, Chelsea, S.W., the Hon. Secretary of the British Committee.

Drunkenness and the Jew.

WHATEVER may be said regarding the halting habits of some temperance advocates, the arguments of those who place themselves in opposition to the practice of abstinence are often in need of orthopædic assistance. Mr. F. Legge declares that the moderate use of alcohol has proved not only a benefit to the individual but to the race, and he urges "that the exhilaration, temporary though it may be, produced by its use, has on the whole made for the welfare of the race, seems to be established by the fact that the European and Mongolian races among whom it has been longest known, and most widely used, are now at the head of civilisation, while those who have most stoutly resisted its introduction, such as the fanatical Semites of Asia and Africa are pretty nearly at its tail." Fascinating though such contention may be in its superficiality, it only needs the slightest dissection to unfold its inherent fallaciousness. If Mr. Legge is desirous of following up his remarkable line of argument, he must turn his attention to the Semite not of Asia but of Whitechapel, and unravel the reason why the Jew in the East-end of London, although living often under conditions worse than his English neighbours, nevertheless never sinks into the slavery of inebriety and, while surrounded by drunkenness and abundant inducements to seek forgetfulness in an alcoholic debauch, is practically never met with "the worse for drink."

Facial Neuralgia.

OF all the sensory disturbances which practitioners are called upon to treat facial neuralgia in one form or another is probably by far the most frequent. Its etiology is quite obscure. Hilton it is true, tells us that neuralgia is the nerves' cry for food, but this is a vague generalisation which does not throw much light on its causation. The affection is not limited to particular countries or climates, but attacks certain individuals irrespective of nationality and *habitat*. As is invariably the case in respect of affections, the nature whereof is ill-understood, the method of treating facial neuralgia are legion, with this peculiarity, that the remedy which relieves one person may prove inoperative when given to another, and may indeed lose its efficacy in respect of the same individual in subsequent attacks. One of the most trustworthy remedies for facial neuralgia not associated with dental lesions is the intensive administration of strychnine. Dr. C. K. Mills, of the University of Pennsylvania, is a great advocate of this method of subduing these painful manifestations. He pushes the administration to the extreme limit of safety, his object being to keep the patient for a time well under the physiological action of the drug. Failing relief by this means, the only alternative is surgical intervention, but this method is hardly within the reach of the average practitioner in view of the gravity and extent of the operations rendered necessary thereby.

The Influence of Development of the Genitals on the Skeleton.

SOME interesting observations have been brought before the Paris *Société de Biologie*, by MM. Launois and Roy, on the relationship which exists between the degree of development of the genital organs and the growth of the lower extremities. In the case of an anorchous subject they noted the extraordinary development of the lower limbs, an abnormality which, they suggest, finds a parallel in the elongation of the hinder parts of animals which have been castrated in early life. Similar aberrations of growth are present in eunuchs, skoptzys, infantile giants, and the like. They infer that the more or less complete development of the genital organs exerts a well-marked collateral influence on the growth of the lower extremities, this being due to delay in the ossification of the epiphyseal cartilages. The point is one of considerable interest, the more so because the popular view long since proclaimed a close relationship between what we may call compensatory disturbances of development. It must not of course be assumed that all long-legged individuals are necessarily ill-developed in sexual respects, for the converse of this observation is obviously true.

The Diagnosis of Enteric Fever.

THE difficulties that surround the diagnosis of typical enteric fever are manifold. Sooner or later the most careful practitioner is certain to find himself cast upon that particular rock which lies ahead of the medical pilot. Various tubercular conditions often closely simulate typhoid fever, and should be carefully excluded from all doubtful cases. Tubercular meningitis and acute miliary tuberculosis are often extremely difficult to differentiate, more especially the latter when complicated with tuberculosis of the intestines, with attendant diarrhoea and swollen abdomen. Even the more chronic condition of tuberculous peritonitis may resemble typhoid fever so nearly as to lead to confusion between the two affections. Perhaps the most common source of evil is to mistake enteric fever for primary pneumonia. The latter malady, when of the extreme type, may be difficult to distinguish. As a complication of enteric fever, it usually occurs in the later stages. The symptoms accompanying appendicitis and perityphlitis often suggest typhoid fever, but the two affections can usually be distinguished by a due consideration of the local signs and symptoms. In its early stages the bowel fever is often mistaken for influenza. Ulcerative endocarditis and pyæmia are occasional pitfalls, especially when the former causes intestinal hæmorrhage from embolism. The intermittent malarial fevers are sometimes very difficult to distinguish from typhoid. Unfortunately Widal's serum test is not invariably positive in its results. It nevertheless offers valuable evidence after the seventh to the twentieth day of the fever, and should be repeated several times where results are negative. A full recognition of the risk of overlooking typhoid fever is

perhaps the greatest safeguard against error that can be placed in the hands of the medical practitioner.

The Monomania of Cleanliness.

THE abnormal dread of this, that, or the other fact or circumstance, when carried to an extreme degree, merges into the region of insanity. A person who is stricken with unreasonable terror upon finding himself in an open space is now recognised by the medical faculty as suffering from that peculiar species of monomania known as "agarophobia." If, on the other hand, the fear results from being in a confined space, as a tram-car, for instance, or a small room, the diagnosis is "claustrophobia," and so on through an interesting little list of monomanias. One of the most curious of these abnormal mental states, perhaps, is that known as "mysophobia," or dread of dirt. It would be somewhat difficult to say at what precise point the virtue of cleanliness has stepped over the border-line between moral virtue and moral madness. In Holland the love of cleanliness is almost universal, that is to say, so far as its outward and visible signs are concerned. It is well known, however, that their most scrupulous and spotless cleanliness often conceals the germs of many deadly "filth" diseases, notably those of typhoid fever. Clearly the mere cleansing of dirty environment, although in itself a desirable and necessary condition of healthy life, can never replace the scientific cleanliness demanded by the modern sanitarian in such matters as pure air, pure water, pure food, good ventilation, housing, and efficient removal of house and town refuse. For all that, a spice of the malady of mysophobia might have an excellent effect if cautiously inoculated among the slum populations of our great towns.

High Game.

THE definition of "highness" in game must clearly be left more or less entirely to the tastes of the individual who proposes to eat thereof. Our grandfathers who went to extremes in so many matters, ran the fashion of eating high game to the end of its tether. One of their attempts to establish a scientific standard whereby to judge of the fitness of their game for table has been handed down to us in the direction to hang two pheasants by the tails until one of them dropped—the other was then fit to be eaten. This ancient authority however, did not save a famous West-end game dealer from being fined last week by a London magistrate for having on his premises a quantity of game unfit for the food of man. It appears the stock in question was found packed in wet ice along with certain fowls, pigeons and rabbits, none of which latter does anyone wish to be the least bit "gamey." The local medical officer of health, moreover, said that ice should be used to preserve food only by way of cool dry air, and not as the defendant used it as a wet, sloppy, direct preservative. On the whole the modern scientific attitude seems to be sound, although it must be admitted

that for some mysterious reason or other, moderately high game can as a rule be eaten with impunity. Nowadays, however, the inscrutable laws of fashion have decreed that game shall no longer be brought to table in an advanced stage of decomposition.

The Plague at Durban.

THE outbreak of plague at Durban, according to the telegraphic information of last week, has assumed a somewhat grave aspect. It appears to have affected both white and coloured population and to have caused already a considerable number of deaths. The serious nature of this invasion is evident in a country of such imperfect sanitation as that which characterises the whole of South Africa. No stronger proof could be afforded of the defectiveness or absence of general public health administration than the endemic and wholesale prevalence of enteric fever in that country. Indeed it is somewhat of a surprise that upon its appearance during the recent war the plague did not run like wildfire throughout the country. However, the germs of a lingering malady are there, and the present outbreak at Durban shows that the danger has by no means passed away. Indeed, now that the cessation of the war has restored general intercommunication amongst the population the risks of distribution of the disease are likely to be greatly multiplied. It is to be hoped that the authorities at Durban will be able to cope with the local outbreak, for anything like a widespread attack of plague would add a disastrous complication to the already tangled web of South African politics.

Eosinophilia in Pelvic Lesions.

MUCH attention has recently been devoted to the condition of the leucocytes in pelvic and abdominal disease. Dr. W. H. Weir (in the current number of the *American Journal of Medical Sciences*) gives the result of routine microscopic examination of all tissues removed in an extensive series of gynecological operations. Eosinophiles, it would seem, take a prominent part in the cellular infiltration associated with inflammatory and suppurative processes of the pelvic organs. In such conditions they usually occur in the largest numbers in the subacute stage and associated with connective tissue hyperplasia. Eosinophilic infiltration is found in most cases of carcinoma of the cervix and in almost all cases of pyosalpinx and ovarian abscess. In inflammatory conditions of the endometrium eosinophiles occur in small numbers and in but few cases. Eosinophiles represent a large proportion of the cells forming the stroma of the mucosa in the normal and diseased vermiform appendix. From the point of view of the pathologist all this is of much interest, but the diagnostician unfortunately receives but uncertain assistance thereby, for in inflammatory conditions of the pelvic organs associated with an eosinophilic infiltration of the tissues the percentage of eosinophiles in the circulating blood is rarely increased, and usually decreased.

Bath-Room Perils.

THE recent tragic death of a well-known philanthropist in a bath-room should call general attention to the sanitation and safety of those necessary household offices. The unfortunate victim was Mr. Quintin Hogg, the founder of the London Polytechnic. Deceased met with his death in a bath-room at the institution in question. The subsequent investigations of the coroner's court showed that his death was due to suffocation caused by the fumes of a patent apparatus attached to the bath for the purpose of heating the water, while at the same time the bath-room was unventilated. From the nature of things the bath-room is almost always of small size, so that the small cubic space is readily deprived of its oxygen and charged with noxious gases. It is a curious fact that the ventilation of the bath-room is often entirely neglected in otherwise well-aired houses. To heat the water by an apparatus discharging its products of combustion into a small unventilated chamber simply amounts to reckless, we had almost said, criminal want of foresight.

The Need for a Uniform Method in Photographic Record.

PHOTOGRAPHIC records of the same subject are frequently misleading and impossible of accurate comparison, because either intentionally or unintentionally, through ignorance or heedlessness, records are made under conditions so dissimilar as to preclude honest contrast and judgment. Dr. J. M. Spellissy (in the December *Bulletin of the University of Pennsylvania*) shows how this unfortunate condition of affairs may be rectified or, at all events, considerably improved. He shows that it is necessary that these should agree upon such fundamental points as focal length of lens, focus and distance of subject from lens front, direction of lighting for recording purposes, size of image and of divisions of chart for comparative illustrations. Certainly if anthropometric and orthopædic record is to prove of permanent service, it is absolutely essential that the haphazard procedures which now prevail should be replaced by standard methods.

Tents and Tuberculosis.

THE astonishing results which have attended "open-air" methods in the combat with consumption have focussed professional attention and aroused public interest throughout the world. Many of our modern dwelling-houses are sadly lacking in hygienic necessities for healthy life, and tend to engender conditions strongly predisposing to consumption. The establishment of elaborate sanatoria for the phthisical is an expensive enterprise. It is interesting, therefore, to find that recent experience has shown that even in a northerly climate treatment in tents may prove of the greatest benefit. The advantages of nomadic existence can be vouched for by many a fashionable vagabond, and the joys of tent life are known not only to many of our colonials, but every year are being realised by a larger number of persons at home.

The holiday camps for the young of our large cities have clearly demonstrated their hygienic utility. For the enterprising there are many countries where tent life may be indulged in without the disadvantages inseparable from a treacherous climate, and there can be no doubt that for those predisposed to consumption by family inheritance or previous disease tent travel offers peculiar attractions and undoubted advantages.

Health Aspects of a Midwinter Holiday.

MANY a man has to take his holiday when he can, and not when he would or should. Fashion, custom, and fancy rule to a very large extent in directing the time of year when mental and bodily rest and change may be secured without running the risk of being charged with laziness or invalidism. But in these days of stress and strain relaxation is a hygienic necessity. For those particularly who are engaged in severe and continuous mental effort, necessitating much of indoor life, and it may be considerable artificiality of life and irritating compliance with conventionalities, a midwinter holiday affords the quickest, surest, and safest means for physical recreation and mental resuscitation.

Hotel Risks.

THE recent loss of life from asphyxiation of a man and his wife in a hotel draws attention to the necessity that exists for the supervision of the sleeping rooms of all such buildings. This has become all the more necessary from the extensive adulteration of coal gas by water gas rich in carbon monoxide. Each artificial illuminant has its own risks; candles and lamps when carelessly used have led to many serious and oftentimes fatal accidents, while electric wires have occasioned death in a bath-room through the failure of their insulation. But the most insidious, and consequently the most dangerous illuminant is water gas, owing to the high proportion of carbon monoxide which it contains. A gas-bracket even in a well-ventilated bedroom is a risk, and in a room in which the ventilation is imperfect the risk is enormously increased. Fortunately the governing corporations of most of our large cities possess the right of examining the accommodation provided by hotels and lodging-houses, and in the case referred to the room in which the death of one and the poisoning of the other traveller took place in a Dublin hotel, was not passed in 1885 by the city architect as suitable for a sleeping room, but as an office, under which designation it appeared in the plan of the building submitted for the corporation's approval. A room passed as an office should not be allowed to be used as a bedroom until the sanitary authorities had examined it and found that the proper arrangements had been made for its ventilation.

THE Carnegie Institution has granted valuable financial assistance to Prof. E. W. Scripture, of Yale University, for the prosecution of researches on the voice, and also to Prof. W. O. Atwater for his work on the respiration colorimeter.

PERSONAL.

DR. J. E. GEMMELL, vice-President of the Liverpool Medical Institute, has been elected President of the North of England Obstetrical and Gynæcological Society.

DR. JOSEPH DAVIES, late medical officer of No. 2 district of the Swansea Union, has been presented with a reading chair with stand and lamps attached, and a silver salver on the occasion of his relinquishing that post.

IN honour of the eightieth birthday of Professor von Esmarch, a gold medal has been struck by order of the German Samaritans' Union, to be presented to those who have specially distinguished themselves in attending to the wants of the sick.

DR. ADAM, of Dingwall, N.B., who has been in practice there for upwards of a quarter of a century, has been presented with an address and a purse containing 450 guineas, part of which is to defray a three months' journey to South Africa to restore his health, which has suffered from his too assiduous attention to professional duties.

SIR CHARLES CAMERON, F.R.C.S.I., C.B., has been awarded the gold medal founded by the late Sir Henry Harben for distinguished service in the cause of public health and advancement of sanitary science. The Harben medal has also been awarded on previous occasions to Lord Playfair, Professor Pettenkoffer, and Lord Lister. We beg to offer our congratulations to Sir Charles Cameron on his well-earned distinction.

THE election to the Assistant Surgeony on the staff of St. Bartholomew's Hospital has resulted in the appointment of Mr. W. McAdam Eccles, M.S.Lond., F.R.C.S., Hunterian Professor at the Royal College of Surgeons of England. Mr. Eccles gained the Jacksonian Prize in 1900 for his essay on "The Pathology and Treatment of Diseases caused by or connected with, imperfect descent of the Testicle," and is the author of a recent successful work on "Hernia, its Etiology and Treatment."

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

NEW PRINCIPAL OF EDINBURGH UNIVERSITY.

AS was generally expected to be the case, Sir William Turner has been appointed Principal by the curators. The new principal is in his seventy-first year, he has taught anatomy in Edinburgh for well-nigh half a century, he is the oldest professor in the University and the honour now paid him is but a fitting crown to a life so inseparably bound up with the university as his is. It is idle to say that his appointment will be hailed with universal rejoicing; a strong man could not have devoted himself heart and soul to the interests of the University for so many years and to such good purpose as to be to many for practical purposes the embodiment of academic authority without coming into conflict with some whose interests were diametrically opposed to those of the University. But apart from these, few will deny that it would scarcely be possible to have got a principal who could do the principal's work as Sir William Turner will. His unrivalled knowledge of university finance, his administrative capacity, his intellectual gifts, and, not least, a genial character

and more than a touch of genuine eloquence, mark him out as one who will adorn the position which he now occupies. Of English descent, he was a Bart's student, and exhibitor and gold medallist of the London University in 1854. In that year he became Senior Demonstrator of Anatomy under John Goodsir, and succeeded his chief in 1867. During the thirty-six years for which he has held the chair his work has been widely known and appreciated, and he probably has one of the greatest reputations of any living anatomist. He has represented his University on the General Medical Council since 1873, with a break of three years, and has been President since Sir Richard Quain's death. He has been Dean of his own faculty, President of the College of Surgeons, Edinburgh, and is Honorary Professor of Anatomy in the Royal Scottish Academy. One of the great works he did for his own University was in the promotion of the scheme for the erection of the new buildings, and upon his shoulders also fell a great part of the work in connection with the erection of the McEwan Hall. He is the author of an "Atlas of Human Anatomy and Physiology," and of "An Introduction to Human Anatomy," editor of Paget's "Lectures on Surgical Pathology," and was a founder of the "Journal of Anatomy and Physiology." His original work on the placenta is well known, and he is an authority on anthropology. By his election to the Principalship he ceases to be a Professor of Anatomy, and delivered his last lecture on Friday, 21st; the work of the class will be carried on by Dr. Hepburn, a personality as well known to recent generations of students, at least, as that of Sir William himself. In meeting his class the morning after his appointment was announced, Sir William Turner received an ovation in replying to which, after paying a tribute to his predecessor, he said, "Gentlemen, the acceptance of one office signalises something that is to follow. I will cease to be Professor of Anatomy. There is such a thing as human nature, and there is such a thing as human strength. Although, as may seem to some of you, I have still a reserve of force, the duties of the new office will render it necessary that certain duties discharged now must be relinquished. . . . the relinquishing of these duties means a great wrench. It is putting behind one a large part of one's life, and when a man has reached the age I have reached, he knows perfectly well that in the ordinary course of nature that part of his life which lies before him cannot be very long. . . . You must now allow me to thank you, and through you to thank all those generations of students who have sat before me all that period of nearly fifty years. I wish to thank you all for the sympathy and the kindness, and I am proud to say the affection, that has subsisted between us during all these years. . . . I should be a very cold-blooded person indeed if there were not firmly implanted in my heart and in my memory all that I owe to the students of the University of Edinburgh."

Correspondence.

PROF. LORENZ'S DEMONSTRATION AT THE CITY ORTHOPÆDIC HOSPITAL.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I have not had an opportunity of discussing this matter with my colleagues since the appearance of your article on Wednesday last, but I am sure they all agree with you and with me that the action of the Press in reporting the demonstration given by Professor Lorenz at the City Orthopædic Hospital on January 14th was not only most objectionable but outrageous.

We did our best to exclude representatives of the public Press from seeing the operations, but it seems that some of them escaped detection. One paper has a medical man on its regular staff, and as all medical men were admitted, he obtained access without our knowing his purpose. Whether other reporters got in or not I cannot say, but I do know that several were stopped and were refused admission. I quite agree with you that something ought to be done to prevent

such unseemly publicity being given to the details of surgical operations in our hospitals, but how to do so is a difficult problem.

We were very desirous that no member of the medical profession who came should be excluded, and there was not sufficient time to organise a more effectual check upon unprofessional visitors.

I am, Sir, yours, truly,
NOBLE SMITH.

London, January 26th, 1903.

Laboratory Notes.

"LOFOTOL."

We have received from Messrs. Southall Brothers and Barclay, of Birmingham, a sample of "Lofotol," which consists solely of cod-liver oil (the purity of which we have established by the application of the British Pharmacopœia and other tests) impregnated with carbonic acid gas, in the same way as an ordinary ærated water. This has the effect of causing a rapid disintegration of the oil, with, doubtless, a greatly increased ease of absorption.

The difficulty of administering cod-liver oil in the case of persons whose digestion is weak, or who are unable to take the ordinary oils without nausea, has led to the preparation of various emulsions, in some of which the diluting body figures so largely that the dose of actual oil is very small.

We warmed a portion of this preparation on the water-bath, and after the effervescence due to the expulsion of the carbonic acid gas had escaped, the oil was cooled to 15.5° C., and the specific gravity taken. This proved to be .9280. The iodine absorption of the oil, which is a valuable test of purity, was found to be 150, and the application of other tests prescribed by the British Pharmacopœia all concurred in affording evidence of its perfect purity and high quality.

The oil, in addition to being absolutely pure, is quite free from products of oxidation, and is consequently of pleasant flavour and taste.

VALENTINE'S MEAT JUICE.

THIS well-known preparation has now been before the public for many years, and has been largely employed by medical men both here and abroad.

Recent samples are characterised by a pleasant and appetising flavour which commend it to those who, weakened by fever, are unable to take or retain ordinary foods, and require a stimulating nutriment.

We have obtained the following figures on approximate analysis:—

| | |
|-----------------------------|------|
| Moisture | 49.3 |
| Total solid matter .. | 50.7 |
| Mineral matter .. | 11.3 |
| Nitrogenous constituents .. | 19.8 |

We would draw attention in particular to the last figure, as in a work by a well-known authority the nitrogenous constituents of this preparation are erroneously given at a much lower figure.

BYROLIN.

BYROLIN, manufactured by Dr. Graf and Co., 25, Cheapside, E.C., is a homogeneous product, the formula whereof has been communicated to us. It is admirably adapted for use as an emollient application to the excoriated or chapped skin, and generally in all forms of dermatitis. It is free from greasiness, and may thus be used as a preventive by those whose integument is specially sensitive to climatic vicissitudes, and to protect the skin after shaving, in intertrigo, &c. Its mild antiseptic properties fit it for employment in gynaecological and obstetrical practice. It may be had scented or not as preferred, and is conveniently put up in collapsible tubes. It is in many respects an ideal preparation.

North of England Obstetrical and Gynaecological Society.

THE annual meeting was held at Manchester on January 16th. The hon. general secretary (Dr. E. O. Croft) read the annual report, which showed that the membership of the society had been well maintained. During the year eight ordinary meetings had been held—at Manchester three, at Liverpool two, at Sheffield two, and at Leeds one. The attendance had been good, and seventy items in the form of papers, cases, and specimens had been contributed. The hon. treasurer's statement indicated that the financial condition of the society continued to be highly satisfactory. The following were elected office-bearers for 1903:—

President, J. E. Gemmell, M.B. (Liverpool). Vice-Presidents: S. Buckley, M.D., W. J. Sinclair, M.D. (Manchester); H. Briggs, F.R.C.S., T. B. Grimsdale, M.B. (Liverpool); T. Kilner Clarke, M.D., C. J. Wright, M.R.C.S. (Leeds); G. H. West Jones, M.R.C.S., Sinclair White, M.D. (Sheffield). Council: A. Donald, M.D., A. T. Helme, M.D., Arnold W. W. Lea, M.D., S. Nesfield, M.D., D. Lloyd Roberts, M.D., J. P. Stallard, M.D., W. Walter, M.D. (Manchester); W. Murray Cairns, M.B., E. T. Davies, M.D., P. Edwards, L.R.C.P., R. Humphreys, M.B., J. McClelland, M.D., A. M. Patterson, M.D. (Liverpool); J. Braithwaite, M.D., H. Littlewood, F.R.C.S., H. Robson, M.R.C.S., A. E. L. Wear, M.D. (Leeds); Percival E. Barber, M.R.C.S., J. W. Martin, M.D., A. A. Payne (Sheffield): Honorary Treasurer: E. Octavius Croft, M.D., 33, Park Square, Leeds. Honorary General Secretary, Arthur J. Wallace, M.D., 1, Gambier Terrace, Liverpool. Honorary Local Secretaries: John Scott, M.D. (Manchester), A. Stokes, M.B. (Liverpool), Walter Thompson, F.R.C.S. (Leeds), Sidney Barber, M.R.C.S. (Sheffield). A cordial vote of thanks to the retiring president (Dr. S. Buckley), proposed by Dr. Lloyd Roberts and supported by Drs. H. Briggs, J. W. Martin, E. O. Croft, and John Scott, was carried with acclamation.

Annual Dinner of the Catholic University School of Medicine.

THE third annual dinner of the Catholic University School of Medicine, Dublin, was most successfully held on Thursday evening last, at the Dolphin Hotel. After dinner, Dr. J. M'Grath proposed the toast of the Medical School. Sir C. J. Nixon, in returning thanks for the School, pointed out that there were now more students than could be accommodated in the present building, and expressed the hope that in the settling up of the University question the School would receive adequate recognition. The toast of the "Past Students" represented by many younger members of the staffs of the city hospitals, by members of the R.A.M.C., and by many medical men in the dispensary, asylum, and other branches of the medical service in the provinces, was proposed by Professor M'Weeny and responded to by Dr. Joseph Roantree, of Newbridge. Professor Coffey dealt with the toast of the "Present Students," and Mr. Robert Cahill replied. Rev. J. Darlington, S.J., Dean in Residence of the Medical School, proposed "Our Guests," to which the Right Rev. Rector, Mgr. Molloy, and Mr. P. Law Smith responded.

Dr. Schunck and Owens College.

We are authoritatively informed that there is no foundation for the statement that the late Dr. Schunck left any pecuniary bequest to Owens College. What he has done is to leave the use of his laboratory and its contents for twenty-five years under certain conditions to the College.

The Mortality of Foreign Cities.

THE annual rate of mortality of the principal Indian and Foreign cities, according to the latest official weekly return, were:—39.6 in Calcutta (including suburbs), 48.5 in Bombay, 19.4 in Paris, 17.8 in Brussels, 12.9 in Antwerp, 17.8 in Amsterdam, 18.0 in Copenhagen, 15.2 in Stockholm, 21.8 in St. Petersburg, 25.1 in Moscow, 18.9 in Hamburg, 18.9 in Munich, 21.1 in Vienna, 25.9 in Prague, 23.0 in Buda-Pesth, 34.2 in Trieste, 27.4 in Venice, 28.4 in Cairo, 35.4 in Alexandria, 17.3 in New York, 18.9 in Philadelphia, 20.2 in Boston.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE BLOOD IN HIGH ALTITUDES.

High altitudes exert a marked effect upon man. Mountaineers are well acquainted with the hampering, and sometimes serious, effect of the so-called *mal de montagne*. Residence at elevated stations exercises a very marked influence on the blood. Drs. Campbell and Hoagland, of Colorado Springs, have recently shown that the blood count increases at the rate of 50,000 corpuscles per cubic millimetre of blood per 1,000 feet. The pulse rate increases in the same ratio as the blood count. The apparent increase in the blood elements is, however, not due to a true multiplication of the blood corpuscles, but arises from changed vasomotor conditions in the peripheral vessels, incident to diminished barometric pressure.

MR. JOHN FLEMING.—We never give advice to inquirers, nor recommend any particular practitioner in these columns. Any qualified medical man in your locality would be capable of relieving the symptoms about which you complain.

MR. J. SIMMONS (Sunderland).—You will find all the information you seek on referring to the special correspondence, page 635, Dec. 10th, 1902: "The Canaries and Madeira in Winter."

M.F.S.—Our contemporary having already made the necessary correction, there is no necessity for us to do so in these columns, the mistake not having appeared herein.

DR. J. S. L.—Kindly send on the M.S., and we will see what can be done with it.

LONDON UNDER WATER.

THE water want of London has long afforded endless subject for discussion. Recently the possibility of tapping the water which, according to some authorities, lies in large accumulation under London has been seriously brought forward. It is, however, necessary to remember that although doubtless as has been contended, such water would be "microbe free" it might not be altogether of the best for dietetic and manufacturing purposes. The expense of sinking deep water rods is considerable and judging from the experience available, the corroding action of the water makes the life of such tubes comparatively short, and when deteriorated fouling of the water supply might readily occur.

Meetings of the Societies, &c.

WEDNESDAY, JANUARY 28TH.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.)—8.30 p.m. Pathological Evening.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover Square, W.)—5.30 p.m. Paper:—Dr. Buckley (Buxton): Local Factors influencing Climate, with Special Reference to Subsoil.

THURSDAY, JANUARY 29TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, W.)—8 p.m. Card Specimens:—Mr. L. Warner, Mr. F. A. C. Tyrell, Major Yarr, and Mr. E. T. Collins. 8.30 p.m. Papers:—Mr. J. H. Parsons: Primary Extra-dural Tumours of the Optic Nerve.—Mr. T. Snowball: Ossification of the Choroid.—Mr. A. S. Morton and Mr. J. H. Parsons: Hyaline Nodules on the Optic Disc.—Mr. L. Warner: Two Cases of Tumour of the Optic Nerve in one of which Krolein's Operation was Performed with Preservation of the Eye.

MEDICAL UNDERGRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.)—4 p.m. Mr. J. Hutchinson, Jun.: Clinique. (Surgical.) 5.15 p.m. Dr. W. S. Colman: The Nervous Manifestations of Rickets.

FRIDAY, JANUARY 30TH.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND (Westminster Hospital Medical School, S.W.)—4 p.m. Ordinary Meeting. Papers:—Mr. F. G. Parsons, Mr. Cameron, and Mr. B. Harman.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL ASSOCIATION (11, Chandos Street, Cavendish Square, W.)—Dr. Wyatt Wingrave, President. Paper by Dr. Jobson Horne: On the Relative Planes of the Vocal Cords; a factor in the differential diagnosis of one. Cases will be shown by the President, Dr. Abercrombie, Mr. Nourse, Mr. Stuart-Low and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.)—4 p.m. Mr. M. Gunn: Clinique. (Eye.) 5.15 p.m. Dr. H. W. G. MacLeod: House Ventilation and Drainage.

THURSDAY, FEBRUARY 5TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.)—8.30 p.m. Papers:—Mr. Noble Smith: Congenital Displacements of the Hips, including a description of Lorenz's method of Bloodless Reduction. Mr. Sidney Spokes: Immediate Regulation of Teeth.

Appointments.

- CHADBURN, MAUD M., M.D.Lond., Surgeon to the Out-patient Department at the New Hospital for Women.
- DAY, H. B., M.R.C.S., L.R.C.P., Junior House Physician at King's College Hospital.
- ECCLES, W. McADAM, M.S.Lond., F.R.C.S.Eng., Assistant Surgeon to St. Bartholomew's Hospital.
- HARPER, JOHN ROBINSON, L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for the Barnstaple Rural District.
- HUGHES, G. W. G., M.R.C.S., L.R.C.P., House Surgeon at King's College Hospital.
- LEE, R. H., M.R.C.S., L.R.C.P., House Surgeon at King's College Hospital.
- LONDON, J. E., M.R.C.S., L.R.C.P.Lond., District Medical Officer of Coventry Union.
- MACNAUL, NORMAN, B.Sc., M.D.Glasg., M.R.C.S.Eng., L.R.C.P.Lond., F.F.P.S.Glasg., Extra Honorary Dispensary Physician to the Royal Hospital for Sick Children, Glasgow.
- MAIR, WILLIAM, M.A., M.B., Ch.B., B.Sc.Edin., D.P.H.Camb., Resident Physician, Leith Public Health Hospital, East Pilton, and Assistant to the Medical Officer of Health for Leith.
- MILTON, JOHN PENN, L.R.C.P.Lond., M.R.C.S., Resident Medical Officer to the Didsworthy Sanatorium for Consumption.
- PRITCHARD, S. C., M.B., Ch.B., Senior House Physician at King's College Hospital.
- REID, R. W., M.B., Ch.B., House Accoucheur at King's College Hospital.
- SHACKLETON, W. WEBB, M.D.Dubl., Joint Medical Officer to the Royal Masonic Institution for Boys at Bushey.
- SMITH, G. FRANCIS, M.R.C.S., L.R.C.P.Lond., Joint Medical Officer to the Royal Masonic Institute for Boys at Bushey.
- TUCK, GNOR LEAN, M.A., M.B., B.C.Cantab., House Physician to the Hospital for Consumption, Brompton, S.W.
- TURTLE, G. DE B., M.B., M.R.C.S., L.R.C.P., Assistant House Accoucheur at King's College Hospital.
- WALKER, JAMES PIXTON, L.R.C.P.Lond., M.R.C.S., Honorary Medical Officer to the Budleigh Salterton Cottage Hospital.

Vacancies.

- Ancoats Hospital, Manchester.—Resident House Surgeon. Salary £100 per annum, with board, residence, &c. Applications to Samuel Baron, Secretary.
- Ayt District Asylum, Ayt.—Two Assistant Medical Officers. Salaries £150 and £120, with board, lodging, laundry, and attendance. Applications to Medical Superintendent.
- Borough Asylum, Canterbury.—Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, and laundry. Applications immediately to the Medical Superintendent, Borough Asylum, Canterbury.
- Borough Hospital, Birkenhead.—Senior Resident Male House Surgeon. Salary £100 per annum, with board. Applications to Chairman, Weekly Board.
- County Asylum, Whittingham, Preston, Lancashire.—Assistant Medical Officer. Salary £150. Furnished apartments, board, washing, and attendance provided. Applications to the Medical Superintendent.
- Johannesburg Hospital.—Nursing Superintendent. Salary £300 yearly, with board, lodging and washing. First-class passage paid to Johannesburg. Applications to Chairman, Hospital Board, Box 1050 Johannesburg.
- Leeds General Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary to the Faculty.
- Liverpool Dispensaries.—Assistant Surgeon. Salary £100 per annum, with board and apartments. Applications to Sam. B. Leicester, Secretary, 56, Vauxhall Road, Liverpool.
- Metropolitan Asylums Board.—Male Assistant Medical Officer. Salary £150 per annum, with lodging, attendance, and washing. Applications, Office of the Board, Embankment, E.C.
- St. Andrew's Ambulance Association. Incorporated by Royal Charter.—Secretary. Salary £250 per annum. Applications to the Chairman of the Association, 103, West Regent Street, Glasgow.
- Weston-super-Mare Hospital.—House Surgeon. Salary £100 per annum, with board and residence in the Hospital. Applications to the Honorary Secretary.
- Whitechapel Union Infirmary, Vallance Road, N.E.—Medical Officer. Salary £130 per annum, in addition to rations, furnished apartments, coal, gas, and washing. Applications to F. J. Tootell, Clerk to the Guardians, Union Offices, Vallance Road, Whitechapel, N.E.

Marriages.

- BRIERLEY—COOPER.—On Jan. 21st, at Holy Trinity, Eastbourne, Edward Edelson Brierley, M.B., C.M., F.R.C.S. Edin., of Cardiff, eldest son of C. E. Brierley, J.P., of Mount Cottage, Rochdale, to Elizabeth Maud, eldest daughter of the Rev. C. B. Cooper, 30, The Avenue, Eastbourne.
- STIRLING—BRIGSTOCKE.—On Jan. 22nd, at H.B.M. Consulate, and at the Bishop's Chapel, Beyrout, Syria, Grote, only son of Captain Charles Stirling (late R.N.), of Cromer, to Mabel Katherine, second daughter of R. Wish Brigstocke, M.R.C.S. (late R.N.), of Beyrout.
- CORY—SHEEN.—On Jan. 22nd, at St. Margaret's Church, Cardiff, Gordon, eldest son of Tr. W. H. Cory, late of Cardiff, Solicitor, to Gertrude, eldest daughter of Dr. Alfred Sheen, Cardiff.

Deaths.

- JACKSON.—On Jan. 21st, at Ingoldshy, Cockington, Torquay, John Jackson, F.R.C.S., aged 83.
- THOMSON.—On Jan. 18th, at 27, Castle Street, Dumfries, Alexander Thomson, M.D., aged 70 years.
- PRATT.—On Jan. 23rd, at Boscombe, Hants., Maria Louisa, widow of the late William Pratt, F.R.C.S., of Newtown, Mont., aged 64 years.

OCULAR HEADACHES. (a)

By SYDNEY STEPHENSON, C.M.,

Ophthalmic Surgeon to the Evelina Hospital, etc.

No symptom, I suppose, falls so frequently under the notice of the medical man as headache, a remark that applies equally to the general practitioner and to the ophthalmic surgeon. It is often a matter of some practical difficulty to trace a headache to its proper cause, although certain types of cephalalgia are generally recognised.

Excluding cases where headache is merely an early symptom of some acute infectious disorder, as typhoid fever, there are several tolerably well-defined groups, of which the following are perhaps the chief: (a) Many headaches, especially frontal ones, depend upon gastro-hepatic disturbances, and can be relieved or cured by attention to the alimentary canal, and, in particular, to the state of the bowels. The coated tongue, and the history of constipation and gastric disturbance generally suffice for the recognition of these cases. That a large proportion of headaches belong to this class is attested by the reputation attaching in the public mind to purgatives in the shape of patent pills, "beans," and so forth. (b) Next, there is the important group of headaches, generally vertical or occipital in seat, more or less intimately bound up with anæmia. It is a familiar observation that such headaches are often relieved by the recumbent posture. (c) A similar kind of headache is common in cases of hysteria or of neurasthenia, possibly because the latter are so often accompanied by a reduction in the nutritive value of the blood. It often co-exists with that classical symptom, the *Clavus hystericus*, too well-known to need description here. (d) Another group is that furnished by patients who have been unlucky enough to contract syphilis. Diagnosis in such cases is facilitated by the fact that the pain is generally most marked at night; that it frequently co-exists with tenderness of the scalp; and that the patient, as a rule, shows other signs of a specific taint. The syphilitic headache, moreover, is somewhat peculiar in that, although it remits from time to time, yet it never altogether ceases. (e) Then, the toxic headaches, often due to the abuse of alcohol or tobacco, or to the retention within the system of waste products, as in uræmia, form a small but important class. (f) Intracranial growths, again, are generally associated with severe headaches of paroxysmal type. In such organic cases, however, other evidences of cerebral mischief will almost certainly be present, except, perhaps, in the earliest stages. The more important of these symptoms, as we all know, are vomiting, giddiness, paralysis, retardation of the pulse, and, above all, double optic papillitis, which (as first insisted on by Dr. Hughlings Jackson) need not be accompanied by any defect in sight. (g) Lastly, there is the important class where

the headaches are distinctly of migraineous type—that is to say, beginning with ocular spectra, lasting for several hours or even the entire day, and terminating with vomiting. The victims generally belong to a good social rank, and the affection is markedly hereditary. Many headaches of this class, as I shall have occasion to show later, are intimately dependent on eye-strain (*asthenopia*), and can be relieved by the provision of suitable glasses.

If a given headache does not fall into one or other of the above groups, its exact diagnosis and correct treatment are likely to be matters of anxiety to the practitioner. Many of the unclassified headaches, however, belong to the group we are the more particularly to discuss, the so-called "ocular headaches"—that is, headaches which are induced or rendered worse by any attempt to use the eyes, especially upon fine objects and under artificial light.

Since the communications of Dr. Weir Mitchell, in 1874 and 1876, which brought prominently before the profession the various head symptoms caused by eye-strain, a good deal of attention has been directed by physicians to the eye as a cause for obscure headaches. At about the same time as Dr. Mitchell's first paper (a) appeared, an extraordinary case, which has since become classical, was brought before the Clinical Society by Mr. R. Brudenell Carter. (b) An undergraduate, whilst reading for honours, was suddenly attacked with symptoms, as palpitation of the heart, headache, and sickness, which were attributed to some obscure affection of the brain, a diagnosis confirmed by physicians both at the University and in London. The patient was sent on a voyage to Australia, but returned no better. He was then told that he must give up all hope of succeeding to his father's business, and abandon a marriage engagement to which he was committed. As Mr. Carter, in reporting the case, says, "His prospects in life were blighted, and his despondency was commensurate with his misfortunes." Mr. Carter found the patient to be short-sighted to the extent of 4.5 D, and after suitable spectacles had been prescribed, all symptoms disappeared. It is satisfactory to add that when last heard of the patient was about to engage both in business and matrimony.

Ocular headaches are commoner than is generally thought. Indeed, it is such cases that help to fill the oculist's waiting-room, and such patients are among his most grateful clients.

As in most instances the connection between the eyes and head goes unrecognised by the patient, how are these headaches to be known for what they really are? To begin with, the ocular origin of any headache should be suspected when it is stated that the pain is brought on by using the eyes, and relieved by rest. Thus, we are often told, that on Sunday, when no strain is put upon the eyes, the pain is better or absent, while it is practically constant during the rest of the working week; or, again, that it is absent during the annual holiday. Under special circumstances, of

(b) "A Practical Treatise on Diseases of the Eye," 1875, page 364.

(a) Paper read on January 9th, 1903, before the Wimbledon and District Medical Society.

course, the reverse may be the case. For example, in one of my patients—a banker six days a week and an ardent amateur artist on the seventh day—headaches are experienced only on the Sunday.

Much the commonest seat of pain is over the brow, and next to that in the temple. I have now and then come across an occipital headache definitely due to eye-strain and relieved by glasses. Vertical and general headaches are not unknown. The pain is usually bilateral, unless there be a marked difference in the refraction of the two eyes, when it, in my experience, is usually worse on the side of the better eye. Pain may present almost any degree of severity, but is apt to be described by patients as a "dull aching" in the affected parts.

Apart from these considerations, the cardinal diagnostic point is that pain, whatever its exact site and nature, is brought on, or at least rendered worse, by using the eyes. A misleading statement now and then heard is that headache is present on awaking in the morning. But in such cases a little inquiry will generally bring out the fact that an unusual demand has been made upon the eyes the night before. Patients do not connect the two things, obvious though that may seem when put into black and white.

It must be borne in mind that ocular headaches are often, though not necessarily, associated with uncomfortable feelings in the eyes themselves. Such are aching, heaviness, fatigue, throbbing, watering, or redness. A frequent complaint is that lines of print become misty and cannot be read again until the eyes have been closed for a few seconds. A sign almost pathognomonic of eye-strain is the existence of slightly reddened eyelids, around the lashes of which is a collection of fine, branny scales. Whenever this type of Blepharitis is seen, one's first thoughts should be of asthenopia. An outbreak of small styes, also, is often a guide, and so is frequent blinking, with or without slight facial contortions, liable to be mistaken for chorea.

In a given case it may be easy or the reverse to elicit these various complaints. Children, especially, are rather apt to complain of a headache only, and to conceal or to disregard the associated symptoms. It may be said in passing that a common complaint in children is that of "colours" around the individual letters of which a printed page is made up.

It should be stated that *Chronic Congestion of the Conjunctiva*, the objective signs of which may be very ill-marked, is apt to give rise to a series of complaints closely resembling those induced by true eye-strain. Thus, the eyes are stated to feel "sandy," and to be hot, burning, and uncomfortable, symptoms all of which become more pronounced towards night. The distinction between the two conditions, congestion and asthenopia, can be made by paying attention to the following points: (1) In catarrh the palpebral conjunctiva will show some signs of roughness or of increased vascularity; (2) the eyelids, in catarrh, are apt to be closed with dried secretion on the patient awaking in the morning or after sleep at any time. Indeed, if on everting the eyelids to examine the conjunctiva, the slightest secretion exists in the conjunctival sinuses, you may safely make the diagnosis of chronic catarrh at once, and forthwith institute a suitable treatment by astringent collyria. It may be worth while to remind you that evidence of traces of discharge may be obtained by dropping into the conjunctival sac a minim or so of a 2% alkaline solution of that curious coal tar derivative fluorescein, which will tinge any shreds of secretion a yellow colour, thereby allowing them to be easily recognised.

Now it is obvious that in headache due to eye-strain the severity of the symptoms will be the result of two main factors: (1) The kind and degree of any refractive or muscular error of the eyes that may exist; and (2) the general state and constitution of the patient.

The kind and degree of the ametropia or muscular anomaly.—The fact may be taken as axiomatic that any kind of ametropia, whether in the nature of hypermetropia, myopia, or astigmatism, may give rise to

headache. But the liability varies much according to the particular kind of ametropia that may be present. My own experience in this matter coincides with that of most other observers, namely, that, of all errors of refraction, slight grades of hypermetropia, with or without astigmatism, are the commonest causes of ocular headaches. The higher grades of hypermetropia—say, anything over 4 D—give rise to so much distress and defective sight that, except in quite young persons, they nearly always fall under the attention of the ophthalmic surgeon sooner or later. It is, however, otherwise with the slighter degrees, where good vision for distant objects is obtained by unconsciously calling the function of accommodation into play. I need scarcely remind you that accommodation is in a state of abeyance in normal eyes when looking at objects twenty feet or more away from the patient. The emmetropic eye, in fact, is so constructed as to focus parallel rays, such as those from a distant object, upon the retina without the exercise of any accommodation whatever, whereas the hypermetrope must exercise to that end just as many dioptries of accommodation as he is hypermetropic. This accounts for the fact that on testing patients with the slighter degrees of hypermetropia with the Snellen types, which are adapted for a distance of twenty feet, normal acuity of vision is frequently obtained. Hence, you must never fall into the fatal error of thinking that the existence of $\frac{1}{2}$ that is normal vision, excludes either hypermetropia or hypermetropic astigmatism as a cause for obscure headaches. The following examples may serve to emphasise this somewhat important practical point:—

| NAME. | AGE. | SIGHT. | REFRACTION. |
|----------------------|-----------|------------------------------------|--|
| William W. | 12 years | 6.5 = better than normal . . . | + 2.75 D spherical + 0.50 D cylindrical @ 60° + 1.0 D spherical |
| Jonathan K. | 9 years | 6/6 = normal. | + 0.5 D cyl. @ 60° + 3.5 D spherical + 0.5 D cyl. @ 150° + 1.25 D . . . |
| Emily M. | 12 years | 6.5 ix. = better than normal . . . | + 0.50 @ 90° + 1.0 D spherical |
| Ethel C. | 10 years | 6/5 = better than normal . . . | + 1.0 D cyl. @ 60° + 1.5 D spherical |
| Catherine S. | 8 years | 6/5 = better than normal . . . | + 1.25 D spherical + 2.0 D spherical |
| Frank A. | 10 years | 6.5 = better than normal . . . | + 2.5 D spherical |
| Joseph S. | 8 years | 6/5 = better than normal . . . | + 0.5 D cyl. @ 90° + 0.50 D spherical |
| Charles P. | 10 years | 6/5 = better than normal . . . | + 1.0 D cyl. @ 90° + 1.25 D spherical |
| William H. | 9 years | 6/5 = better than normal . . . | + 0.50 D spherical |
| Wm. John W. | 10½ years | 6/5 = better than normal . . . | + 1.0 D cyl. @ 90° + 1.25 D spherical |
| Alfred B. | 7 years | 6.5 = better than normal . . . | + 0.50 D cyl. @ 90° |

There would be no difficulty in multiplying instances of this kind, but enough have been adduced to point the plain moral, namely, never to exclude the possibility of a headache being due to hypermetropia or astigmatism merely because the patient's distant vision is normal. Neither does testing with the near-types render us much assistance in these cases, inasmuch as the smallest type will be fluently read by hypermetropes of low grade, at all events until they

have passed the age of 40 years or thereabouts. In my experience, such cases must be tested with the ophthalmoscope under the influence of some agent that, when dropped into the eyes, is capable of temporarily paralyzing the ciliary muscle, as atropine, or its methylbromide salt (in children) or homatropine (in adults). My own practice under such circumstances is almost completely to correct the astigmatism, supposing the latter to exist. I nearly always order the glasses to be worn for all purposes.

As examples of headache caused by hypermetropia or hypermetropic astigmatism and relieved by glasses I quote the following cases, selected from among a considerable number of which I have notes:—

Alice B—, æt. 35, had suffered from headaches since she was fourteen years of age. They were slight at first, but became much worse as she got older. They had latterly occurred about four times a week, and as they usually lasted all day, they practically incapacitated her from work. They began, as a rule, with "specks floating before the eyes," and now and then terminated with vomiting. They were described by the patient "as a throbbing and sharp pain all over the head." The eyes used to smart and feel strained when reading small print by gas light. Medical treatment of the most varied kind had been tried but without affording relief. On October 14th, 1901, when I examined the patient, I found no muscular deviation; and after estimating the refraction under a cycloplegic, I ordered for constant wear R.E. $\begin{matrix} + 0.25 \text{ Sph.} \\ + 0.75 \text{ Cyl. } 180^\circ \end{matrix}$.

L.E. $\begin{matrix} + 0.25 \text{ Sph.} \\ + 0.50 \text{ Cyl. } 80^\circ \end{matrix}$. Miss B— was seen again fourteen months after her pince nez had been prescribed. She reported that during the period in question she had not suffered from half a dozen headaches all told; that the pain had been much less severe and had lasted quite a short time; and that her eyes now never felt tired, no matter how much they were used. I tried in vain to induce Miss B— to leave off her glasses, in order to see whether the headaches would return with their former violence.

Jane C—, æt. 22, reported that for six months past she had experienced "a pulling at the back of the eyes," and that since she was a child she had been subject to severe headaches two or three days a week. The pain was mainly in the frontal region, especially over the left eye, which was stated to run with water. When examined on November 30th, 1899, she could read the smallest type, and her distant sight was greater than normal ($V. = \frac{5}{6}$). Under a cycloplegic, refraction was estimated, and the following spectacles ordered for constant wear, viz., R.E. $\begin{matrix} + 1.75 \text{ Sph.} \\ + 0.50 \text{ Cyl. } 60^\circ \end{matrix}$.

L.E. $\begin{matrix} + 1.50 \text{ Sph.} \\ + 0.50 \text{ Cyl. } 60^\circ \end{matrix}$. On November 28th, 1902—that is, nearly two years after the glasses were prescribed—I again saw this patient, who reported that, after the glasses had been worn for about a week, the headaches and other symptoms disappeared completely, and had not recurred.

Percy P—, æt. 21, a student of medicine, had suffered so severely from frontal headache and nausea that his parents had seriously thought of putting him to some less arduous occupation. Medical treatment had been as varied as it was unsatisfactory. Vision $\frac{2}{3}$, and No. 1 Jaeger's types. No muscular imbalance (*orthophoria*). Under a cycloplegic, the patient was found to be affected with slight hypermetropic astigmatism, with oblique and asymmetrical meridians. He was ordered for constant wear R.E. $\begin{matrix} + 0.75 \text{ Sph.} \\ + 0.25 \text{ Cyl. } 80^\circ \end{matrix}$. L.E. $\begin{matrix} + 0.75 \text{ Sph.} \\ + 0.25 \text{ Cyl. } 110^\circ \end{matrix}$. After using these glasses for two weeks, he completely lost his headaches, and the same had not recurred the last time I saw the patient, three and a quarter years after he had obtained his spectacles.

George A—, æt. 29. Headaches, described as violent, frontal, and occurring, on the average, twice a week, since his seventh year. They were induced by employing his eyes on fine objects. The patient wore glasses +1.75 D, which he had obtained

from a "qualified optician." He was, upon examination, found to have 2 D of hypermetropia, with the small amount of 0.25 D of astigmatism, axis horizontal. After fully correcting this trifling astigmatism, but otherwise leaving the spherical glass as it was, the patient got rid completely of his headaches.

The foregoing cases have been specially selected because they illustrate the following practical points:—

- (1) That it is the low degrees of hypermetropia and especially of hypermetropic astigmatism that have the greatest tendency to give rise to headaches.
- (2) That in such cases the sight at the distant types is usually normal or even better than normal.
- (3) That it is of vital importance to correct even such low degrees of astigmatism as 0.25 D or 0.50 D.
- (4) That the greatest discomfort, as in the third case quoted, is likely to be met with when astigmatism is asymmetrical as regards the two eyes, or when it is "against the rule"—that is, when the axis of the cylinder is horizontal or nearly so instead of being, as is the rule in hypermetropic astigmatism, vertical or nearly vertical.
- (5) That the ametropia must be estimated under the influence of a cycloplegic, as atropine or homatropine. It may be remarked that the relief to the pain obtained during the use of these agents is sometimes very marked. When this is the case, you may safely promise that the headaches will be cured by glasses, although the converse is not invariably true.

I have already insisted upon the point that the possession of normal vision—the so-called *relative visual acuity*—does not exclude the existence of hypermetropia or of hypermetropic astigmatism. The contrary, however, is the case with the other forms of ametropia, i.e., myopia, myopic astigmatism, and mixed astigmatism. Every one of those defects reduces the normal acuteness of vision, but, unfortunately, from the physician's point of view, errors of refraction other than hypermetropia and hypermetropic astigmatism are relatively seldom the effectual causes of ocular cephalalgia. The following, therefore, is quoted as an exceptional case:—Andrew G—, æt. 22; was seen on January 21st, 1897, complaining of paroxysmal pain in the forehead and temples, of several years' duration. The attacks occurred, on the average, once a week. $V. = \frac{5}{8}$ brought to normal with

$\begin{matrix} + 1.0 \text{ Sph.} \\ - 3.0 \text{ Cyl. } 180^\circ \end{matrix}$. The constant use of these glasses freed the patient from all discomfort, and, when seen on August 1st, 1902, he assured me that he had never experienced a moment's pain since he had used them.

(To be concluded in our next).

PUERPERAL INSANITY. (a)

By ROBERT JONES, M.D.Lond., M.R.C.P.
Resident Physician and Superintendent, London County Asylum, Claybury.

THIS paper is based upon a personal experience of 259 cases of puerperal insanity, divided into 120 cases commencing during the actual puerperal period, 83 during lactation, and 56 during pregnancy. Insanity occurs once in every 700 confinements. It is of a characteristic form after confinement, amounting to an almost nosological entity; but this is not the case during pregnancy or during lactation, there being no definite type of insanity occurring in connection with these two stages. The divisions are, however, more convenient than typical. The following propositions may be advanced:—1. The insanity of pregnancy is more common in first confinements among single women, the disappointment, shame, and disgrace of illegitimacy being an important factor in the mental breakdown. 2. During the pregnancy the mental condition is more often acute melancholia than acute mania, and suicidal symptoms, which occur in 41 per cent., have to be carefully guarded against. 3. The insanity of pregnancy is divided into that occurring during the early

(a) Abstract of paper read before Meeting of Obstetrical Society of London, January 7th, 1903.

months and that occurring during the later months, and in these the nearer the insanity in point of time to the confinement the more acute are the mental symptoms. Insanity is not more frequent when the sex of the child is male. 4. The insanity of the puerperium comes on after the first confinement in 33 per cent. of the cases and supervenes suddenly rather than gradually. 5. The cases which occur during lactation present characters of marked general physical exhaustion and mentally are more often of the depressed than of the maniacal form. Lactation insanity becomes chronic oftener than the insanity of the other periods. There is a tendency to low forms of inflammation, thrombosis, gangrene, and phthisis during the insanity of lactation. Both suicidal and infanticidal promptings are more common in lactation than in puerperal cases—that is, in cases where insanity commences more than six weeks after confinement. 6. The early symptoms of threatening insanity are loss of sleep and headache, and these should be a forewarning of mental breakdown. The busy delirium of hallucinatory type ending in acute restless, purposeless mania with religious and erotic delusions, is characteristic of this variety. 7. As regards etiology, heredity is more marked and in the direct maternal line in puerperal and lactational insanity and is equally paternal and maternal in the insanity of pregnancy. A previous record of hysteria is frequent in puerperal insanity. 8. The pathology is that of heredity and stress. Is the stress due to toxin? 9. As regards prognosis, cases of insanity during early pregnancy improve towards the end of pregnancy, whereas those of late pregnancy become worse at the puerperium. Puerperal insanity is markedly recoverable. Improvement is often rapid, being often complete in three months, but generally taking from four to five months. 10. With regard to treatment, all cases presenting headache and sleeplessness must have absolute quiet and rest, and sleep must be procured. Home treatment is desirable in all cases if possible. Unusual and sudden impulses of suicide and infanticide must be guarded against. The presence of the husband aggravates the symptoms. There is much necessity for a liberal and stimulating dietary. Change is necessary in puerperal insanity when cases tend to become stuporous. Menstruation is a sign of mental improvement. Purgatives and iron are well borne. The following special questions were put forward by way of criticism. 1. Was there such a disease as puerperal insanity—a mental alienation which was either caused by the puerperium or an accompaniment of this physiological crisis? 2. If there was, were the mental conditions due to toxæmia or to septicæmia, or to both? Or was the delirious mania which occurred in connection with this period due to extraordinarily emotional disturbances? How far did the moral factor enter into the etiology, and how far did pregnancy in the unmarried state influence the causation of insanity? 3. What was the relation between mania and melancholia? 4. What was the essential pathology of this disease? 5. What was the relation between albuminuria and pregnancy? and also between albuminuria and the puerperal state? 6. In Dr. Jones's cases, so far as the history could be obtained from the relatives or those present, no prodromata of insanity beyond sleeplessness and headache were as a rule noticed, and the onset of insanity was sudden; what was the nature of the onset in the practice of obstetric physicians? 7. As to prevention and treatment, did hysteria in youth manifest itself by insanity in later life at the puerperal or other physiological crisis, and should marriage be discountenanced in these? What views should be generally held as to the marriage of neurotic persons? What were the views as to home and asylum treatment, as to local and general treatment, and, a more especially important point, as to the induction of premature labour?

THE Twenty-first Congress and Exhibition of the Sanitary Institute is to be held at Bradford, commencing on July 8th, 1903.

AFTER-MEDICAL TREATMENT IN CASES OF OVARIOTOMY. (a)

By A. RABAGLIATI, F.R.C.S. Ed.,

MRS X, æt. 30, came to consult me from an East Yorkshire town in June, 1902. She was the mother of one child, æt. 4, and had been expecting another, which, however, did not arrive. After waiting for another month, on the theory that she had probably miscalculated the time of the expected event, there was still no confinement. It seems that there had been no cessation of the catamenia at all; and I was told that at each return of the period patient was kept in bed, and had some medicine given to her to stop the flow. When no accouchement ensued as expected, a consultation was held, when the diagnosis of ovarian tumour was made, and immediate operation was advised. Thereupon she came and placed herself in my hands. I found the abdomen much and uniformly enlarged, dull all over, and with an easily perceived fluid wave. There was a large nodulated boss in right ileo-inguinal region and right lumbar, but there seemed to be less dullness in right than left flank, and although I inclined to the view that we had to do with a right ovarian tumour, still I did not feel justified in coming to a positive diagnosis. (It turned out too, at the operation, to be a right-sided ovarian tumour.)

There was a fluid wave apparently outside the tumour as well as inside, and it seemed to me that besides the tumour there was some collection of ascitic fluid. I did not recommend immediate operation, as I believed that patient would probably do better if she were put to bed, and had her diet regulated for a week or two before operation. The chief object of this communication is not to describe the operation, which has been done now many thousands of times, so that every practical surgeon knows all that it is necessary to know or to do in that respect; but it is to connect the digestive disturbances of the patient and her food habits with the growth of the tumour and the surgical necessity incumbent on us of removing it. I therefore pass on to say that the diet which I recommended as a preparation for the operation was that she should have a glass of milk or a cup of cocoa made with milk or a cup of tea morning and evening, and a basin of soup with a slice of bread and a little cooked fruit in the middle of the day. This advice was given after inquiry had been made into the previous history, and was followed for about a fortnight. The previous history was to the following effect: Patient, a pale, pasty-looking, thin, and anæmic, or as I prefer to call it, triphthæmic, woman, had suffered for years from heart-burn, indigestion, and constipation. In addition she had had periodic attacks of headache, and of vomiting, which she termed "bilious attacks." She might have had one of these as often, sometimes, as once a week. She had four meals a day—breakfast, dinner, tea, and supper, at 8.30 a.m., 12.30 p.m., 5 p.m., and 8.30 p.m. of ordinary mixed diet. Thinking that her bilious attacks, which very much annoyed her, might be due to her food-habits, she made various changes in her diet; stopping, among other things, the bacon and eggs which she had been accustomed to take

(a) A paper read before the Bradford Medico-Chirurgical Society, January 14th, 1903.

at breakfast-time, but did not perceive much benefit from this change, perhaps a little. For about a year her bilious attacks had been fewer and her headaches perhaps a little less severe than formerly. No doubt this was due—at least, I have no doubt it was—to the fact that the excess of material ingested into the body by her four daily meals, over and above what was required for the effectual and sufficient nourishment and enrichment of the blood, was attracted to the tumour and went to feed that. The tumour-growth, in fact, was the method adopted by Nature to find a use for the surplus material being ingested into the blood, and was, therefore, like all of Nature's methods, salutary, so far as it went. This being so, the connective tissue of the body, and particularly that about the head (she had general *initis*, or connective tissue lymph-congestion, as nearly all anæmic or triphthæmic women have), was less overfed than before, and so the general disturbance of nutrition was less.

The operation was performed on July 2nd, Mr. Percy Lodge giving the anæsthetic and Mr. Miall assisting me. The tumour of solid and fluid contents was somewhat large, and might weigh about 25 lbs., but there were no adhesions and no more difficulties in removal than a little care and manipulation easily overcame. The preparation of the skin and the general arrangements of the operation were the usual ones, and do not call for any particular remark. Neither does the subsequent recovery, except that it was very slow. Catheterisation was required till July 7th, but after the silk-worm-gut sutures had been removed and an aperient administered, control of the bladder was recovered. The abdominal wound, or, at least, its outer part, took on a grey, somewhat sloughy appearance and was not healed till the beginning of September; but at no time did the condition cause me much anxiety, for although the temperature rose to 101.5°, the pulse was never above 106 (on the third day), and was generally below 100, and at the end of a week was between 80 and 90. The wound smelt rather faint and somewhat of fermentation, notwithstanding the constant use of antiseptics, boric acid, &c. I attributed that not to any failure in antiseptic applications, but to the long-continued indigestion from which the patient had suffered previously to the operation. This indigestion, and particularly her four daily meals, the tetrasiteism to which she had so long subjected herself, a new meal being continually ingested before the previous one was digested, appeared to me to have induced a certain amount of sapræmia, and to have rendered her tissues less capable of sustaining the effects of a surgical operation and less capable of healing afterwards than they ought to have been, and than I think they would have been had her digestion and blood-making processes been in a better state. Even after the operation, and although the patient was fed on a very spare and fluid diet, she suffered a good deal from indigestion from time to time. Whatever she took seemed to disagree with her, so that occasionally she would abstain from all food but water for a day or so at a time. I recommended various changes in the diet in order to rectify these disturbances, trying two daily meals for some time, and again recommending one. She seemed to do best on the last or monositeous plan; and so I recommended her to keep to that, with a cup of tea morning and evening, and nothing to eat at those times.

Throughout the time during which I was seeing patient the question of the causation of the tumour was frequently referred to. I pointed out to her that mere removal of the tumour was not in itself a very momentous matter if the causes which led to its formation were allowed to continue unchecked. If this were so, although the tumour had been removed and could not recur, still other things might occur and must occur in the body if the causes which led to its formation were suffered to continue. A tumour of the other ovary, for example, might occur. And here I ought to say what I omitted when mentioning the operation—that I then found the left ovary cystic, and, withdrawing it from the abdomen, incised the cysts, letting the fluid escape; and, stitching the openings up with catgut, returned the ovary to the abdomen. Occurrence of a left ovarian tumour was not, therefore, a very unlikely event. The initial steps to this had, indeed, been already taken. In fact, I have seen an ovary sacrificed at operation for no more cause than I found in my patient's left organ. Or the stump of the removed tumour might take on malignant action unless we could deal with the causes which led to the formation of the tumour. I have known this to occur in my own practice, a woman from whom I removed a very large ovarian tumour, which appeared to be quite simple (but how heterologous ovarian tumours are, albeit we are accustomed to consider them simple!) dying some years afterwards in the Bradford Cancer Hospital of a malignant growth springing from the stump of the removed ovary. And, of course, it is well known that simple ovarian tumours are apt to be followed after some years by malignant growths. (I infer from these facts, I may say, that there is no difference in principle between the causes of simple growths and those of malignant. The causes of the one appear to me to be the same as the causes of the other. The chief difference between them is the difference in the length of time during which the causes have been in action.) Or other things might happen in the life history of the woman, the occurrence of rheumatism or gout, for instance, or an attack of influenza and pneumonia, or a great variety of possibilities might overtake her, unless we could get to know and to understand what were the causes which led to the formation of the tumour in the first instance. For although it is not necessary to know causes in order to treat effects, and although this statement is particularly true of surgical treatment in which we frequently, or even as a rule, combat effects without making the slightest reference to causes; still, causation and to know causes is of paramount importance in preventive medicine, and also, I may say, in preventive surgery. If, therefore, the patient was to have a healthy life in future, it was absolutely necessary to get to know the causes of her illness, and a very poor thing to blow and brag about the progress of surgery, which had made such an operation possible—as is too often done. My patient was as anxious on this point as I was myself. But the causes of her tumour were patent. The tumour had no doubt come from the blood, or, rather, the excess of material laid down in the tumour, the fluid and solid material infiltrating and enormously hypertrophying the natural ovarian structure, came from the blood. But, of course, the blood got it from the food, the function of food being to make blood, and the function of blood being to nourish the body. And it was quite plain from

the history of the long-continued indigestion and constipation and of the recurring headaches and bilious attacks, that for a long time the blood had been improperly made, and no doubt loaded with large quantities of ill-assimilated material, out of which the tumour had been formed. In plain English, the woman had been taking too much food; and I advised her for the future to take less. She had been taking too many meals, and I advised her to take fewer. There had not been sufficiently long intervals allowed to occur between her meals, and I advised longer intervals, so that one meal should have time allowed it for complete digestion before the next was taken. I tried her with two meals, but she still had headaches; whereupon I recommended her to be monositeous, that is, eat once daily. She asked me if I thought this would be sufficient for her, as she had to do her own work as they were not able to afford a servant. I said I thought it would. The following letters from Mr. X. complete the history of the case up to the present time. Mrs. X. left Bradford on September 19th or 20th. On October 12th, Mr. X. writes to me: "I have not forgotten my promise to write you respecting Mrs. X., but thought it best to wait a while before doing so. She still continues to live on one meal a day, and finds it quite sufficient for her. On two occasions she tried two meals, but felt sorry for it afterwards. She has not had a bilious attack since she came home, and only one very slight headache. She is much stronger and gaining flesh. She weighed 6 st. 9 lbs. when she returned, but has not been weighed since." On October 27th he writes again: "Mrs. X. has been weighed to-day and finds she has gained 5 lbs. during the six weeks she has been at home. On September 15th she weighed 6 st. 9 lbs., and now weighs 7 st. She still keeps to one meal a day. She keeps free from bilious attacks."

Such, gentlemen, is the after-medical treatment recommended and carried out in a case where it was necessary to remove an ovarian tumour surgically. The reasoning which has led to its recommendation on my part, and to its adoption on the part of the patient, has convinced me of two things besides. (1) If I had removed the tumour simply, saying nothing about the causes which led to its formation, I believe I should have done the woman harm and not good, because I should have removed, so to say, the ash-pit of the body without seeing to it that the excess of ash formation and collection was put an end to. The skin, bowels, lungs, and kidneys were evidently incompetent to do the scavenging required, and I should not have taken any steps to lighten their work. Proving unequal to it before, they would have proved unequal to it again, and some other calamity must have happened to the woman. (2) Had this woman been advised, say, two years ago to live in this way, I believe she would not have had the tumour, and would not have required any surgical operation for its removal. And how many cases of this kind and of many other kinds are now quietly and insidiously perparing themselves for operations which would be quite unnecessary if the patients were now being advised to live differently from the ways they are now pursuing I leave to the imagination and to the reflection of my hearers. Obviously the same reasoning applies to the after-medical treatment of cases treated surgically for the removal of a vast number of growths, hypertrophies, formations, &c.—a number so vast that it is quite impossible to do more than hint at

them now. From this point of view, many surgical diseases are preventible as well as medical ones; and many surgical operations, now absolutely necessary owing to the existing states of patients, might be obviated.

December 24th, 1902.—This patient, having come over to Bradford to spend Christmas with her relatives, I have had an opportunity of seeing her. Things continue to go on well with her. She has no indigestion, no headaches, or only the slightest suggestion of headaches now, and no bilious attacks at all. Her constipation is much less, and she never takes aperients. Her weight is about the same. She thinks she may have lost a pound. She does all her own house-work, except the very hardest parts of it. She tells me that some of her friends have of their own accord begun to follow a disiteous régime, and that a friend of hers, who suffered from frequently recurring bilious attacks, and who thought to cure them by taking exercises but without altering her diet, continues to have her headaches just the same.

THE RELATION OF CONSTIPATION TO ANÆMIA.

By JAMES BURNET, M.A., M.B. Edin.,
M.R.C.P. Edin.,

Formerly Resident Physician, Royal Infirmary, Edinburgh.

MANY of the leading members of the profession deny that constipation has any relation to anæmia. They assert that anæmia may lead to constipation, but in their opinion constipation is never the cause of anæmia. These authorities deny the truth of the auto-intoxication theory, and maintain that retention of waste products is not, after all, such a bad thing for the patient as some would have us believe. Although I was firmly convinced in my own mind of the absurdity of these contentions, I recently resolved to make a special note with reference to all cases of anæmia or of constipation that came under my notice. I have done so for the last eight or nine months, and am now in a position to state definitely my findings on the subject.

Taking cases of chlorosis first, I have, during the period mentioned, seen some sixty cases or more. Every one of these, without a single exception, had to admit that the bowels did not move every day. About 5 per cent. complained of diarrhoea, and in these on palpation of the colon I readily made out that it was filled with accumulations of fæces. In many cases pain in the left iliac fossa was the one symptom complained of, and this, I have no doubt, was due to pressure of the loaded colon upon a sensitive ovary. Certainly after having the bowels well emptied every one of these patients ceased to experience the pain formerly complained of. Not only so, but by simply ensuring a daily free evacuation of the bowels, many cases of simple chlorosis ceased to complain of palpitation and drowsiness, although at this time no drug had been specially prescribed for the blood condition. Not a few of these cases had previously been under the care of another medical man, who had been prescribing Blaud's pills or tinct. ferri perchlor. without any apparent benefit. And no wonder; for no amount of iron will cure the patient suffering from chlorosis, while at the same time her intestinal tract is occluded by poisonous material.

Again, I have notes of several cases where the

symptoms varied from loss of energy, pains in the chest and back, to cold feet and foul breath. Every one of these had a pale and somewhat sallow look. In one case the pain complained of was in the region of the gall-bladder. There were also headaches, faintness, nausea, and loss of appetite. The patient was a housemaid. She had a foul tongue and a horribly stinking breath. On examination I found the colon almost throughout its entire length loaded with lumps of hardened fæces. Repeated enemata of soap and water, alternated with olive and castor oil injections, brought away an incredibly large amount of waste material. This gave great relief, and later by careful dietetic and drug treatment the patient became altogether a new being. In another patient, a woman, æt. 50, the complaint was "displacement of the womb." This was the diagnosis given by another practitioner. The patient told me her bowels moved regularly every day, but on examination the rectum was found loaded and the womb in its natural position. This patient was very bloodless-looking, but improved remarkably after repeated small doses of cascara. Her appetite, which had previously fallen off greatly, soon returned, and she was able to do her work better than she had done for many a day. A third patient complained that nothing she ate would "lie on the stomach." She had been to several doctors, one of whom told her the "coating of the stomach" was diseased, another that she had an ulcer, while a third said the patient was suffering from congestion of the liver. When I saw her she was much emaciated, and was very pale. In answer to my inquiry, the patient said her bowels moved every day. I examined her very carefully, but could find nothing gastric to account for her symptoms. On rectal examination the same old condition presented itself. The rectum was loaded with scybala, and yet the patient said the bowels moved every day. Under treatment directed to her constipation the patient soon recovered.

Now these cases go to prove the utmost necessity which exists for making minute inquiry in every case presenting itself for treatment as to the state of the bowels. As a rule, the patient's own statement should not be too readily taken for granted, and in all doubtful cases careful palpation of the colon should be had recourse to, and, if necessary, a rectal examination made as well.

That constipation causes retention of waste products and consequent deterioration of the patient's health there can be no doubt. My own cases alone go to prove this, and the sooner these facts are recognised the better. In every case of anæmia, from whatever supposed cause, the intestinal tract must be regarded as of prime importance. Treatment will not improve the conditions present unless we first ensure that our patients' bowels are moving daily and regularly. It is not enough to obtain an affirmative answer to our question; we must make sure of the facts for ourselves. Few patients, and women more especially, seem to look upon constipation as existing if the bowels move at all. Sometimes no constipation is stated to exist when perhaps one motion only occurs in a week or a fortnight. If, however, the gums and conjunctivæ are pale, and the patient's symptoms at all vague, it will pay to attend to the bowels first and consider the diagnosis later.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.
MEETING HELD JANUARY 7TH, 1903.

PETER HORROCKS, M.D., F.R.C.P., President, in the Chair.

DR. ROBERT JONES opened a discussion on "Puerperal Insanity," an abstract of which will be found on page 103.

Sir JOHN WILLIAMS insisted upon the peculiar condition of the nervous system in pregnancy, parturition, and the puerperal state, and deprecated resort to surgical measures in the treatment of this form of insanity.

DR. G. F. BLANDFORD pointed out that the earliest symptom of approaching mental trouble was loss of sleep, and this should be most closely watched and every precaution taken that the patient should not be disturbed. With regard to the question whether the mental disturbance was due to toxæmia or septicæmia, or both, he recalled the fact that toxæmia and septicæmia were different things, septicæmia producing puerperal fever, not puerperal insanity.

DR. G. E. HERMAN opined that the main duty of the general practitioner and the obstetric physician in regard to puerperal insanity was to prevent it. Treatment was mainly in the hands of the alienist. To prevent puerperal insanity the great things were to see that the patient got food and sleep. In insomnia the best hypnotic was alcohol. There were objections to alcohol of which in the present day no one was in danger of losing sight. Every hypnotic, in too large doses, did harm, but the harm done by alcohol, if taken too freely, was far less and far slower in coming than that done by chloral, bromide, morphia, sulphonal, or any other hypnotic, if taken habitually for long periods.

Medical men were not justified in taking upon themselves the responsibility of discountenancing a proposed marriage. The utmost that a medical man should do was to communicate to the interested parties whatever apprehensions he might have as to the result of marriage.

DR. C. A. MERCIER took exception to the statement that headache was a common prodrome of puerperal insanity. The only trustworthy indications, he said, were sleeplessness and loss of appetite. He did not think that single women who became mothers suffered much emotional stress as a rule. Many of them were already half-witted and the insanity of the puerperium was only an exaggeration of their usual state. The rest were for the most part upon a low moral plane. He protested strongly against the suggestion that puerperal mania could be treated satisfactorily at home, and maintained that treatment in special institutions was always preferable.

DR. F. H. CHAMPNEYS concurred in all that had been said about sleeplessness as the most striking symptom of threatening insanity, and as to the pre-eminent value of alcohol as a sedative in such cases. He thought that if mental distress were a factor in producing puerperal insanity its frequency after illegitimate births ought to vary directly with the moral standard. It was well known that the moral standard with regard to such matters varied greatly in different countries. If this were valid the proportion of cases of insanity in single mothers ought to be lowest in immoral and highest in moral countries. As regarded toxæmia and its relation to pregnancy he did not think that the explanation given by the author was altogether adequate. Effete products were doubtless prevalent after confinement; on the other hand, the sense of physical and mental comfort and relief ordinarily experienced after delivery was proverbial. He did not think that this would be the case if ordinary toxins were the usual cause of insanity after labour.

DR. W. LLOYD ANDRIEZEN remarked that the division into insanity of pregnancy, of the puerperium, and of lactation was a conventional and not a noso-

logical classification. A careful study of statistics showed that illegitimate pregnancy was twice as frequently followed by mental disorder as legitimate pregnancy. He regarded puerperal insanity as comprising three main types of mental disorder—viz., first a collapse delirium following upon parturitions attended with marked exhaustion and hæmorrhage; secondly, an acute confusional insanity with hallucinatory delirium (frequently misnamed "mania"); and, thirdly, mania or melancholia proper, or alternating manio-melancholic insanity.

Dr. F. W. MOTT commented on the fact that among the large number of cases recorded by the author there was not a single case of gangrene; and he related an instance in a woman certified as suffering from puerperal insanity who was admitted into one of the London county asylums. This patient not long after admission developed signs of symmetrical gangrene of the feet. The child had been born dead and the woman was suffering from septic endometritis. Her mental condition improved when this was treated.

Dr. R. PERCY SMITH thought that next to sleeplessness, restlessness and early confusion of thought were more important early symptoms than headache. No definite form of mental disorder could be looked upon as absolutely characteristic of puerperal insanity, and cases might be of the delirious, confusional, maniacal, melancholic, stuporous, or delusional type. He had little personal knowledge of illegitimacy as a cause, but called attention to Dr. T. S. Clouston's statement that 75 per cent. of the puerperal cases admitted to Morningside Asylum followed illegitimate births. Another point in the etiology was that 26 per cent. of the cases admitted to Bethlem Hospital had had a previous attack of insanity, either before or after marriage, which was not puerperal in origin. Alienists constantly found a history of previous "hysteria" in patients admitted to asylums which when carefully inquired into was found in many cases to have been a previous attack of definite mental disorder euphemistically called "hysteria." He insisted that such patients ought not to marry.

Dr. E. W. WHITE thought that the author's proportion of occurring cases was too low—probably 1 in 400 confinements was nearer the mark—for there were many which did not go to the asylum for treatment, and no records were therefore obtainable. He drew attention to the obscene language, erotic tendency, and self-abuse, probably of peripheral origin, from abnormal uterine conditions, altered lochia, &c., which such patients exhibited. In nearly all his cases there was an elevation of temperature of from one to two degrees in the evening, with a morning fall of a degree or less, lasting from ten days to a fortnight, then a sub-normal temperature for several weeks.

Dr. W. S. A. GRIFFITH pointed out that there was a distinct group of cases in which the main feature was the apprehension of the patient, either real or simulated, that unless the pregnancy was terminated she would become insane; he looked upon all such cases with the gravest suspicion, not of insanity, but of rather the reverse—namely, as an ingenious method of putting strong pressure on the medical adviser to procure abortion.

Dr. T. SEYMOUR TUKE agreed as to the necessity for good feeding and urged early resort to artificial feeding. He admitted the great value of alcohol, but they must not lose sight of the danger of forming a habit.

Dr. T. CLAYE SHAW said that it appeared to him that there were two classes of cases both characterised by the delusions, incoherence, and other mental symptoms supposed to be pathognomonic of insanity due to the puerperal state alone. Insanity characterised by prominence of sexual mental demonstration might occur in young women at the developmental epoch or in women of middle or advanced age in whom there was no uterine or ovarian complications of any kind to be passed through, just as delusions of a sexual character might be seen in boys and men accompanied by acts of masturbation, and yet there was no occasion to attribute the symptoms to influence from the genital

organs. When, however, the temperature was higher than was usually met with in acute insanity; and the symptoms came on shortly after parturition, there was a strong argument in favour of a direct connection between the mental and bodily states, especially when there was a history of hereditary taint, together with the probability of the presence of a septic condition.

Dr. J. M. AMAND ROUTH urged the desirability of having intermediate receiving houses, or nursing homes, where women suffering from such temporary insanities as these could be received and treated. This would avoid the stigma of residence in an asylum and would make it easier to get the friends of the patient to agree to removal.

The PRESIDENT remarked that obstetricians saw these cases at a much earlier stage usually than alienists. Perhaps for this reason the author had said little as to diagnosis. When a patient was admitted into an asylum the diagnosis had already been made, but in the earlier stages it was not always easy to decide that the symptoms amounted to actual insanity. He considered that the refusal of food was a far graver symptom and pointed much more certainly to insanity than did sleeplessness.

BRITISH LARYNGOLOGICAL RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

GENERAL MEETING HELD JAN. 30TH, 1903.

The President, Dr. WYATT WINGRAVE, in the Chair.

At the PRESIDENT'S request, the Secretary read a letter from Mrs. Lennox Browne, in reply to the letter of condolence sent her in the name of the Association on the occasion of her husband's death.

The PRESIDENT then referred in suitable terms to another loss the Association had sustained in the death of Dr. Hunter Mackenzie, and it was agreed to send a letter of condolence to his widow.

The following cases were then shown:—

1. A case of laryngeal tuberculosis in a man, æt. 45, by the PRESIDENT.

Dr. ATWOOD THORNE spoke on the advisability of treating such cases out of London, or in some such healthy neighbourhood as Hampstead.

2. A case of laryngeal tuberculosis in a woman, æt. 35, by Mr. CHICHELE NOURSE.

The PRESIDENT thought that had it not been for the presence of undoubted signs of pulmonary disease in this case, there would be good reason to hesitate as to the diagnosis.

3. Cases showing the beneficial action of mucin in atrophic rhinitis, by Mr. STUART-LOW.

Dr. P. H. ABERCROMBIE testified to the great benefit derived from the treatment in several of his hospital patients.

Dr. J. STEWART MACKINTOSH also spoke in favour of the treatment, and referred to its beneficial action on the stomach and bowels, and the relief of pain in malignant disease of the rectum.

Dr. PEGLER inquired as to the *modus operandi* of the mucin.

Dr. WYLIE had seen good results in several cases of atrophic rhinitis treated with mucin.

Dr. JOBSON HORNE suggested that the massage employed along with the mucin might account for part of the good result obtained, and asked how the internal administration of mucin could affect atrophic rhinitis.

Dr. VINRACE wished to know if it was an accepted fact that deglutition was impossible with the neck over-extended, as Mr. Stuart-Low had stated in his paper, and also asked if the forcible nasal syringing advised by Mr. Stuart-Low was not liable to injuriously affect the sinuses.

The PRESIDENT congratulated Mr. Stuart-Low on his results with mucin. He thought that not enough time had yet elapsed for the treatment to have had a thorough trial. The good effect on digestion he regarded as of great importance. He suggested that the alkali

present in the tabloids of mucin might have something to do with the good results.

Mr. STUART-LOW, in replying, thanked the Fellows for the great interest taken in the subject, and described the *modus operandi* of mucin to be local and general. It inhibited bacterial growth and was hygroscopic and cleansing, and it supplied the natural moisture which was defective in these patients. He admitted that the massage carried out by the surgeon was beneficial, but that cases had benefited markedly without the massage, and only with the mucin. Mucin acted as a protective coating to the stomach, and it was the natural protector.

4. Two cases of adhesion between the soft palate and the posterior pharyngeal wall, the result of tertiary syphilis, operated on with good results by Dr. P. H. ABERCROMBIE.

Dr. VINRACE thought that the openings would gradually lessen in size as time went on.

Mr. NOURSE said that considering the great discomfort arising from the nasal obstruction in such cases he thought it wise to do all in one's power to give relief. And he thought systematic dilatation of the openings might be advisable.

The PRESIDENT congratulated Dr. Abercrombie on the good results following his operations, and remarked how much relief might be obtained in such cases with even very small openings.

5. Cases of deflected septum, treated by Moure's operation, together with the septotome devised and used by the contributor, by Dr. HEMINGTON PEGLER.

Dr. DUNDAS GRANT congratulated Dr. Pegler on the excellent results obtained. He regarded it as a distinct gain to correct the deformity without making a septal perforation.

Dr. JOBSON HORNE regarded Dr. Pegler's instrument as better than the original one.

6. Specimen and slides of a cystic cholesteatoma from the supra-tonsillar fossa, by the PRESIDENT.

7. Microscopical section of epithelioma of the nostril, by the PRESIDENT.

8. Section of the new growth in the larynx shown at the last meeting, by Dr. JOBSON HORNE. It proved to be an endothelioma.

9. Coloured drawing by Dr. JOHN STEWART MACKINTOSH of naevus of the throat, shown at the last meeting by Dr. P. H. ABERCROMBIE.

10. A case of attic suppuration successfully treated by simple incision and irrigation by Dr. HEMINGTON PEGLER. In this case, the suppuration had, unfortunately, set in again.

Mr. STUART-LOW protested against the use of irrigation in cases of chronic ear suppuration, as tending to drive infection into the mastoid antrum and cells, and set up acute mastoid symptoms.

11. Dr. DUNDAS GRANT read the notes of several cases of radical mastoid operation, one in which facial paralysis occurred the day after the operation, with ultimate almost complete recovery from the palsy.

Dr. FREDERICK SPICER inquired as to the time of onset of the facial paralysis, and as to the supposed cause whether direct injury at the time of operation or inflammatory pressure afterwards.

Dr. WYATT WINGRAVE then delivered his Presidential Address on "Tobacco Deafness."

Dr. DUNDAS GRANT proposed a vote of thanks to the President for his excellent address, and Dr. VINRACE seconded this.

Mr. LANG, speaking as a visitor, said he had seen many cases of retinal and optic nerve affections as results of the abuse of tobacco, but he had not noticed deafness in association in these cases. Perhaps this might be explained by the fact that it had not been looked for carefully and that the deafness in these cases was particularly for low tones. He intended to be on the outlook for deafness in such cases in the future.

MR. R. HENSLOWE WELLINGTON, M.R.C.S., L.R.C.P., Deputy Coroner for the City of Westminster and the South-West Division of London, has been called to the Bar.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD JANUARY 16TH, 1903.

Dr. G. E. SHUTTLEWORTH in the Chair.

DR. G. A. SUTHERLAND and Mr. THOMSON WALKER read a paper on a case of
SYPHILITIC ENDARTERITIS AND NEPHRITIS IN AN INFANT.

The disease of the cerebral arteries was that first described by Heubner. The authors agreed with Friedlander and Baumgarten in regard to the importance of changes in the vasa vasorum of the adventitia in this process. Syphilitic arteritis was rare in congenital syphilis, only a few cases being found in the literature. They looked upon the condition as being a secondary rather than a tertiary manifestation. The renal condition was an interstitial nephritis, and was to be distinguished from the congenital syphilitic kidneys described by Stoerk. The connection between syphilis and such cases of interstitial nephritis was not, the authors considered, merely accidental. It was possible that the condition had been frequently passed over, for some cases had been reported in which no macroscopic change was found, but microscopically interstitial nephritis was found.

The paper was discussed by the Chairman. Dr. LEONARD GUTHRIE considered that the views expressed by the authors bore out his own opinion, namely, that chronic interstitial nephritis in children was often due to syphilis.

Dr. ROBERT HUTCHISON showed the kidneys from a child, who possibly belonged to the group described by the authors of the paper.

Dr. GEORGE CARPENTER offered some remarks, and Dr. SUTHERLAND replied to the discussion.

Mr. THOMSON WALKER showed specimens of (a) traumatic cephalhydrocele, and (b) punctured fracture of the skull.

Mr. SYDNEY STEPHENSON described a case where paralysis of the cervical sympathetic on one side had followed the evacuation of a retro-pharyngeal abscess. The symptoms were characteristic, and included exophthalmos, ptosis, contraction of the pupil, and lowered intra-ocular tension.

Dr. EDMUND CAUTLEY inquired whether any changes were noted in the state of the blood-vessels or the function of sweating on the affected side.

Dr. G. A. SUTHERLAND also discussed the case and Mr. STEPHENSON replied.

Dr. LEONARD GUTHRIE showed an infant, æt. 5 months, suffering from an unusual kind of microcephaly. There was, in addition, general spasticity of all the limbs. The child's features did not suggest imbecility.

Mr. A. H. TUBBY entered a protest against operating upon such cases. His experience in that direction had been uniformly unfortunate. Craniectomy appeared to be powerless to cure the condition. The case was further discussed by Drs. Cautley and Hutchison, Mr. G. Pernet, the Chairman, and Dr. Sutherland.

Dr. LEONARD GUTHRIE replied.

Dr. CHARLES W. CHAPMAN read notes of a case of dilatation of the stomach in a girl, æt. 8. The patient had been accustomed to unsuitable food, taken at irregular intervals. Under suitable treatment the child made a complete recovery. The case was discussed by Drs. Sutherland and Cautley, and

Dr. CHAPMAN replied.

Dr. GEORGE CARPENTER read notes of a case of "acute primary thyroiditis in a rachitic infant, æt. 14 months." The disease proceeded to suppuration, the abscess was opened, and the patient recovered. He called attention to the rarity of the condition, even as a complication of the specific fevers, and pointed out that in some reported cases induration of the gland and not suppuration had resulted as a sequel of inflammation.

DR. T. N. KELYNACK has been elected Honorary Secretary of the Society for the Study of Inebriety.

ROYAL ACADEMY OF MEDICINE IN IRELAND.
SECTION OF SURGERY.

MEETING HELD FRIDAY, JANUARY 23RD, 1903.

SURGERY OF THE GALL-BLADDER.

MR. MCARDLE brought forward a number of cases to illustrate, first, the method of applying sutures to the gall-duct before opening over a stone impacted therein, thus rendering the procedure of very short duration. Secondly, instances of gall-stones simulating cancer of the stomach where operation effected a complete cure. Thirdly, cases where adhesive bands joined the colon to gall-bladder and liver producing dilatation of the stomach. Fourthly, tumour of the gall-bladder leading to symptoms simulating chest trouble, dyspepsia, and inducing mental distress. In all of these, the proper treatment of the gall-bladder was thoroughly effectual in relieving the patient of the secondary troubles which were so distressing.

MR. FAGAN said, in regard to Case 3, of Mr. McArdle's paper on surgery of the gall-bladder:—Patient middle-aged, suffered for five years from severe epigastric pain and vomiting. Seen by me September, 1901; case had then been diagnosed in London as cancer of pylorus. On examination stomach dilated upwards, displacing apex beat of heart; downwards reaching umbilicus to left, two inches to right of middle line. A narrow, dull area lay to right of this and still more to right a second resonant area (combined percussion and auscultation method was used). Gave Ewald's test meal, and had gastric contents examined at Laboratory of Trinity College. HCl and pepsine pronounced present in normal amounts. Hence the diagnosis referred to, and the recommendation to have an operation done.

SIR THOMAS MYLES said:—The difficulties of diagnosis in cases of gall-stones without jaundice were often very great. He described a case in which a lady, *æt.* 34, subject to violent attacks of pain had been brought to him by Dr. Rice, of Portarlington. Examination showed a greatly dilated stomach and a floating kidney. He was at first inclined to attribute the symptoms to the floating kidney, but determined, after consultation with Professor Dwyer, to make an exploratory incision in the middle line. This was done and an elongated tube line gall-bladder more than nine inches in length was brought into the wound, opened, and 98 small white calculi removed therefrom. Sir Thomas Myles asked Mr. McArdle for his views on the question of complete closure of the gall-bladder in these operations and the frequency of ventral hernia after suture of gall bladders to parietes.

The Section then adjourned.

ULSTER MEDICAL SOCIETY.

MEETING held in the Medical Institute, Belfast, on Thursday afternoon, at 4 o'clock,

Dr. JOHN CAMPBELL, the President, in the Chair.

Dr. J. T. Creery, Coleraine; Dr. Dryden Stead, Belfast; and Dr. A. Trimble, Belfast; were elected Fellows of the Society; and Dr. J. E. MacIlwaine, Belfast; and Dr. Prudence E. Gaffikin, Belfast; were elected Members.

Dr. HENRY WHITAKER, medical officer of health for the city, opened a discussion on "The Notification of Infectious Diseases" and the working of the Act in Belfast. A special note was added to the notice of meeting sent to members saying that the Council had heard with great regret the charges made in the City Council and elsewhere with regard to notification of infectious diseases without sufficient grounds, and that, while they had not sufficient evidence to warrant them taking direct steps in the matter, they had arranged this meeting, and specially requested a large attendance of members, as such allegations seriously involved the honour of the profession.

Dr. WHITAKER made a lengthy statement giving particulars (excepting the names) of a number of flagrant

cases of abuse of the Act, but rather stultified himself by saying that he had never prosecuted a medical man, and hoped he never would.

Dr. O'NEILL, who is a member of the Town Council and of the Health Committee, followed, speaking most strongly concerning three medical men in particular. When pressed for their names he gave them privately to the President, who said that one of the three was a member of the Society. Dr. O'Neill said that the Public Health Committee were determined to prosecute whether Dr. Whitaker wished it or not. He referred to the disgrace brought to the city by numbers of cases being notified as typhoid which were not so at all, the city thus getting a worse reputation for unhealthiness than it deserved.

Dr. GARDNER ROBB, attending physician to the Fever Hospital, criticised Dr. Whitaker and Dr. O'Neill's figures severely, showing that in reality there was even more typhoid than the figures showed.

After some remarks from Dr. WILLIAMSON and Dr. KELVIN,

Dr. CECIL SHAW moved the following resolution:— "That this Society exceedingly regrets to hear the statement, made by the medical officer of health regarding the working of the Notification Act, but they do not consider that they have the necessary authority to deal with cases of groundless notification, and believe that the public authorities who are responsible for the bringing into force of the Act are also responsible for the detection and punishment of any, if such exist, who act dishonestly in carrying out its provisions." This resolution having been seconded, Professor LINDSAY moved as an amendment that the whole matter be referred to the Council to consider, and Dr. Whitaker having promised to aid the Council in obtaining evidence of [the alleged dishonest practices, the amendment was carried by a large majority.

Dr. KILLEN showed two interesting eye cases—one an eye destroyed by a piece of metal, and the other a soldier with a specific history, who had suffered from double ophthalmoplegia externa. The affection was still marked in one eye, but under specific treatment was rapidly clearing up.

France.

[FROM OUR OWN CORRESPONDENT.]

ADHESIVE PERIGASTRITIS.

PARIS, February 1, 1903

At the meeting of the Société Médicale, M. Duplant spoke on adhesive perigastritis, which, he said, was a frequent complication of gastric ulcer. During the last year he was able to collect seventeen cases, verified either by laparotomy or by autopsy. The large majority of the cases concerned the left side of the epigastrium. The affection was quite amenable to clinical observation and examination by well-defined signs and symptoms. Making its appearance at the terminal period of gastric ulcer, perigastritis furnished two subjective signs—pain and vomiting, which should attract the attention of the attendant. The pain which had its seat in the epigastrium was liable to appear at any hour of the day or night after or before meals; it is not modified by the nature of the food taken nor by the changes in the position of the body, nor is it made better or worse by the absorption of food.

The constancy, the long duration, the seat of the pain between the appendix and the umbilicus, were signs of great value. The character of the pain was described by patients as a painful sensation of weight or constriction at the epigastrium.

The vomiting was rarely that of food; it was generally that of acid liquid, clear or more or less opaque from the presence of mucus derived from gastric catarrh, which accompanied old ulcers.

The above symptoms, although of great value, were not in themselves sufficient to affirm the existence of the affection (adhesive perigastritis), if the objective signs were not present and discovered. Several cases must be observed.

(1) No tumour or swelling was apparent in the epigastrium. Exploration, on pressing the wall under the costal edges, revealed an abnormal resistance, giving a sensation of induration, ill-defined, but compared to a flat cake.

(2) The wall of the epigastrium appeared to be under tension and slightly bulging forward. The aspect was due to peritoneal effusion.

(3) The perigastritis appeared under the form of a hard superficial mass, due to the inflammatory neoplasm situated at the periphery of an old ulcer. It made one suspect the existence of cancer, especially if it coincided with emaciation.

All those symptoms, subjective or objective when they lasted for years, became aggravated at each attack, and were accompanied by all the signs of cachexia.

The progress and the prognosis of the perigastritis was in direct relation to the condition of the ulcer. If the ulcer be definitely cured, the perigastritis would assume a slow evolution, insidious at the beginning, but always chronic, with slight subacute attacks. When the peritoneal induration was formed, which corresponded with the complete cicatrisation of the ulcer, the syndrome of the perigastritis was definitely created, and led the patient to progressive cachexia, frequently fatal, and in any case irremediable by medical means.

The treatment consisted in rest in bed and a dietary régime of eggs, milk, raw meal, butter and cream.

When that treatment was not sufficient to ease the pain and the vomiting, a surgical operation should be thought of, not limited to the breaking up of the adherences, which always returned, but gastro-enterostomy as performed by M. Pinatelle, as the radical cure of ulcer. By it absolute rest was insured to the stomach. Unfortunately before patients would accept surgical interference their condition was very low, rendering them unfavourable subjects for a successful issue.

Germany.

[FROM OUR OWN CORRESPONDENT]

Berlin, January 31st, 1903.

At the Society for Internal Medicine Hr. Westenhoeffer related a case of

MILIARY TUBERCULOSIS AFTER ABORTION.

The patient was a woman, æt. 27, who had aborted four weeks when she was admitted into hospital on August 11th with fever ranging between 39° and 40° C. and collapse. The history showed that the fever immediately followed the abortion. She died on the 15th. The autopsy revealed general miliary tuberculosis of all the serous membranes and of the internal organs. The endometrium was especially infected. The tissue was free but the veins were full of caseating tubercle. This was the source of the general tuberculosis. There was old caseating tubercle in the left tube and a patch less extensive in the apex of the left lung. The speaker observed that when a patient had suffered for four weeks continuously from fever after delivery the case could not be one of sepsis. It was very difficult to distinguish between sepsis and pyæmia. That was important, as where surgical interference was possible the diagnosis pointed out the spot, but

with sepsis any operation would be useless. He did not think the plæenta or fœtus could have been infected although it was not examined, as the disease began after the abortion.

Hr. Guttmann related a

CASE OF DIABETES AND ACUTE PANCREATITIS.

A woman, æt. 41, was admitted into hospital in a state of diabetic coma. The urine contained 4.52 per cent. sugar acetone and acetic acid. Death took place two days after. Section showed great wasting and typical diabetic kidneys. The pancreas, not deformed, weighed 50 grammes. The microscope showed it full of leucocytes everywhere; no hæmorrhages, no abscess, no necrosis. There were no bacteria, and the exit passages were intact. He did not believe that the disease in the pancreas stood in any causal relationship to the diabetes, as the diabetes had existed for years and the pancreatitis was acute.

Hr. J. Boas related a case of

CHRONIC ULCERATIVE COLITIS.

with demonstration. The case was that of a single woman, æt. 28, who came under his treatment after suffering from intestinal trouble for four years. She complained of diarrhœa four or five times daily mixed with blood and pus, and she was much reduced. Examination of the abdomen showed nothing but moderate tenderness over the colon and slight tympanitis. Microscopic examination of the stools showed Charcot-Leyden crystals, no amœbæ, and no tubercle bacilli. Urine normal. A diagnosis was made of ulcers of the colon, which was neither syphilitic nor tuberculous. The treatment consisted of regulated diet and irrigations, but no permanent benefit resulted from these. Then, as the patient was so greatly reduced weighing only 80 kgrm., operation was thought of, as successful cases had been published, and on April 21st, 1901, Steiner did a temporary colotomy with a favourable result. Systematic washing out of the colon was now instituted, the most successful being that with a solution of iodine. At first the stools were recta but they soon became cæcal. It was difficult to decide when the cæcal opening should be closed. Regular examination of the returned water used in flushing even seven months after the operation showed crystals and some pus. The opening was, therefore, not closed until March, 1902. A small fæcal fistula remained, as was usually the case, but this soon closed. The result was excellent. The patient had daily evacuations (after water enemata) of healthy stools, and her body-weight had greatly increased.

The speaker then related a second case that had been operated on by Körte. Her recovery was not so simple, although the patient was better. In any case the method of treatment appeared to be suitable in serious cases.

Hr. Körte remarked, in connection with the last case, that he had done a cæcotomy in December, 1901, for chronic dysentery, after which all possible washings out were put into practice, but without result. Nine months later he had separated the ileum from the cæcum so that all fæcal matter could escape from the ileum. The washings out had to be stopped on account of the exquisite pain they caused. At present the patient was somewhat better, her weight had increased. Possibly after a while the fistula could be closed, but blood and pus still came away with the stools. The case showed that operation did not ensure success.

Hr. Stiener said that the chief factors were the prevention of the passage of fæces over the ulcers, and the medicinal and mechanical flushings out. These should be very copious—five to six litres. He had

postponed the definite closure of the fistula until, after three weeks' temporary closure, the stools had ceased to cause irritation to the diseased parts.

Hr. Ewald did not expect such favourable results. In a case observed by himself an opening was made in the descending colon without result. Then Trendelenberg made one in the ascending colon, again without favourable result. Some improvement took place occasionally, but after a while the patient got worse again, and now after six years no considerable change had yet taken place.

Hr. Körte said that his patient at once lost her fever and her pain after the operation, and so far the operation was very advantageous.

Hr. Boas would distinguish between ulcerative and amœbic colitis; the latter could be readily cured by ipecacuanha

Hr. Krause said that in Vienna and Gratz recent amœba colitis was rarely seen. The prognosis was not bad. The disease could be cured with cer.ainty with calomel.

Austria

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 24th, 1903.

SYPHILITIC DEFORMITY.

Neurath showed to the Gesellschaft a child, æt. 6, presenting deformities, the result of inherited syphilis. The arms were quite rigid. All the joints were the seat of spindle-shaped swellings. The lower extremities were similarly affected, more particularly the knees and ankles, which were markedly bent. Immediately above the elbow- and ankle-joints abnormal mobility was perceived, due to separation of the epiphyses. The Röntgen ray showed no dark shadow at the margin of the bone.

CARCINOMA LARYNGITIS.

Osker brought forward a seaman, æt. 56, who had the larynx totally extirpated four and a half years ago for carcinoma of the larynx. No return of the disease had so far shown itself. He could swallow well, and had a voice or sound that can be heard thirty metres on a still sea without the aid of any instrument. This operation was performed by means of the "circular stitch" in closing the orifice, which he considers to be a great advantage in closing the trachea after resection, as by this means the cicatricial walls are still left mobile.

Koschier at the same time showed five other patients on whom he had operated two years ago. One of the cases had the right vocal cord with surrounding frames removed; in two he did unilateral extirpation of the larynx; and in the other two hemi-removal of the larynx along with the entire epiglottis. Only one of the patients has shown any symptoms of local recurrence in the region of the tongue. These favourable results were obtained, he thought, by using Mikulicz's tampon, whereby the secretions could be prevented from irritating the bronchi.

MALFORMATION OF SPLEEN.

Sternberg showed the internal organs of a female, æt. 75, in whom no trace of the spleen could be discovered. The arteria linealis was altogether wanting, so that no doubt remained in the minds of the observers that this was a congenital defect. The mesentery and retro-peritoneal lymphatics were unaltered. Beyond the absence of the spleen no other abnormality existed. Toldt, in his text-book, relates seventeen cases of absence of the spleen, and of these thirteen had other malformations. Clinically, nothing abnormal had ever been

observed, and the patient died from tuberculosis of the lungs, æt. 73.

CHRONIC PIGMENTARY URTICARIA.

Schwoner next showed a child, æt. 2, with urticaria pigmentosa chronica, from which it had suffered for two months. The hairy part of the scalp and the forehead and neck were white with yellow patches slightly infiltrated with a xanthomatic efflorescence on the body and extremities. In other places there were confluent patches of a dirty reddish-brown colour rising above the level of the skin. It was distinguished from syphilis by its absence on the hands, face, soles of the feet and buttocks.

CYSTOSCOPE AND SUTURES.

Kapsamer related two cases in which he had used the cystoscope to remove stitches which had accidentally found their way into the bladder from the wound of an operation for calculus. In both cases immediately after the operation the patients began to complain of frequent micturition with cloudy urine, which subsequently became purulent and blood-stained. Various cystic sedatives were employed, but with no relief. At last the cystoscope was resorted to and the bladder examined internally, when in both cases sutures were seen hanging from the wall of the bladder. After their removal the cystitis disappeared, and the patients recovered in a very short time. After the operation, the sutures, two in number, appeared to have formed a fistula in the wall of the bladder, and were found together on the internal surface of the organ. He also exhibited other two cases where he had cauterised ulcers on the internal surface of the bladder by the aid of the same cystoscope.

THERAPAUTIC VALUE OF JONEN.

Pauli read an elaborate dissertation on the therapeutical properties of jonen, which has a chemical formula of $C_{13}H_{20}O$, being an isomer of iron $C_{13}H_{20}O$ in the naphthol group. This substance, he maintains, is a valuable agent in measuring the metabolisms of the albuminoids and salts in the body. There was a close relationship between the cyanide of jonen and the nitrate, bromide and iodide of the same substance, as may be observed chemically. The cyanide of jonen is useful in catarrhs and acne, and has a sedative effect particularly in the cephalalgia of advanced syphilis. Its specific indication is, however, in arterio-sclerosis.

The Operating Theatres.

WEST LONDON HOSPITAL.

FOUR ABDOMINAL OPERATIONS AS THE RESULT OF APPENDICITIS.—Mr. SWINFORD EDWARDS operated on a young man, æt. about 25, who had been admitted with a pelvic abscess. The following history was obtained: A month before he had evidently had an attack of appendicitis, when he was seen by a surgeon, who did not consider an operation advisable, and the patient got much better after careful medicinal treatment. A short time afterwards, however, he began to get worse again; he got more abdominal pain, the temperature went up, the tongue became furred, and there was difficulty in getting the bowels open. At the time of admission his temperature was 101° , the pulse somewhat rapid, and the tongue furred; he looked in much distress, presenting an anxious appearance. In the hypogastric region there was a well-marked swelling, and on introducing a finger of one hand into the rectum with the other hand on the hypogastric region, a large pelvic abscess was revealed. The abdomen was opened in the middle line, and some coils of small intestine were

found matted together in the hypogastric region ; on separating these coils the abscess was found. Its area having been packed round with strips of bicyanide gauze, it was freely opened, giving exit to, close on a pint of pus ; the cavity was well washed out, a large rubber drain inserted, and the abdominal wound closed. On account of this intra-peritoneal suppuration no attempt was made to find the appendix, although the matting of intestine proceeded from the abscess towards the right iliac fossa, pointing to the appendix as having been the cause of the trouble. The patient was much improved by this operation, and appeared to be about to make a rapid recovery, when increasing difficulty in getting the bowels open took place, and three weeks after the first operation complete obstruction set in, which could not be overcome by any aperient medicines or enemata. It seemed clear that this was due to mechanical obstruction caused by binding down of knuckles of small intestine to the original area of inflammation ; accordingly, a second operation was undertaken. An incision was made in the right iliac region as for appendectomy ; on approaching the cæcum, a small abscess cavity was opened in which lay a good-sized concretion, the cæcum at this point had ulcerated through. The opening was accordingly stitched up by Lembert's sutures, and the appendix looked for. It was found to be unusually long, and about its middle bent at an acute angle, giving it a V-shaped appearance. It was freed and removed ; its walls were somewhat thickened, but there did not appear to be any rupture or ulceration of it. A central incision was now made in the middle line of the abdomen, thereby opening up the old fistulous tract into the pelvic abscess ; three coils of intestine were found to be adherent and tightly bound down in this situation. One was freed, but it was found impossible to do so with the other two, so, to relieve the obstruction, a distended piece of small intestine was opened and stitched to the abdominal wound in the right iliac region, a temporary enterostomy being thus performed. This brought the patient considerable relief, and he much improved for two or three days ; the trouble now was that the intestinal secretion, being very acid, produced considerable excoriation all round the wound area ; indeed, the edges of the wound became partially digested ; it was clear that the sooner this temporary opening in the bowel was closed the better it would be for the patient, provided that intestinal anastomosis was first carried out. The abdomen having therefore been again opened in the middle line, the small intestine was traced downwards from the junction of the duodenum and jejunum. It was then found that the jejunum had been opened about two feet from its commencement, which accounted for the very irritating nature of the intestinal contents. The small intestine was now traced from the artificial anus towards the obstruction, and a loop of ileum above the obstruction drawn out ; the ileum was now traced backwards from the ileo-cæcal junction also towards the obstruction ; this part of the intestine was not more than a foot long. With this portion the loop, which had been first drawn out, was now united by means of a Murphy's button, and the central abdominal wound closed, the artificial anus being left untouched. Four days after this there was a slight action of the bowels *per anum*. As a preliminary to closing the artificial anus the spur was destroyed without the employment of an anæsthetic by the use of a large pair of pressure forceps which are known by the name of pedicle forceps. Two days after this Mr. Edwards freed the opening in the jejunum from its union with the abdominal wall ; having thoroughly cleansed this part of the gut it was

sewn in a transverse direction, Halsted's sutures being employed. The gut having been returned as far as possible, the edges of the abdominal wound were not approximated, but a tampon of gauze inserted. Mr. Edwards drew attention to his having only opened the abscess at the first operation without attempting then to remove the appendix, which would have been difficult to find among the matted intestines ; besides, he had judged it more prudent to wait, because of the presence of so much intra-peritoneal suppuration. With regard to the removal of the appendix at the second operation, he pointed out that he had simply excised it and sutured the stump, as he considered the performance of the coat-sleeve method would have occupied too much time, for the sewing up of the cæcum at the point of ulceration had already taken some time, and he had to proceed to the opening of the fistulous tract in the middle line and the separation of the adhesions of the intestines. He thought it unfortunate that the portion of intestine which he had stitched to the abdominal wall had proved to be situated so high up in the small intestine, the secretion here being so acid as to produce great excoriation, besides partially digesting the edges of the wound ; but at the time of stitching he had naturally chosen the most distended part he could see. At the next operation he said he had sewn up the intestine in a transverse direction with Halsted's sutures in order to interfere as little as possible with the lumen of the bowel. He pointed out that still another operation would have to be undertaken in this case, and this, the last, would consist in closing the abdominal wound.

Ten days after the last operation the patient was doing well. Fæces had passed *per anum*, but then Murphy's button had not yet come away.

Society of Apothecaries of London.

THE following candidates passed in the examinations during January :—

Surgery.—W. M. Emmerson (Sections I. and II.), W. T. Harris (Section II.), A. R. Henchley, G. Lucas, (Sections I. and II.), M. E. S. Scharlieb (Sections I. and II.), H. G. Sewell (Sections I. and II.).

Medicine.—E. F. Beaumont (Sections I. and II.), F. G. H. Cooke (Section I.), W. E. Denniston (Section I.), L. E. Ellis (Section I.), W. M. Emmerson (Sections I. and II.), A. E. Henton (Sections I. and II.), H. Jacques (Section I.), T. G. Longstaff (Section II.), C. C. Rushton (Section II.).

Forensic Medicine.—R. Appleton, E. F. Beaumont, F. G. H. Cooke, W. E. Denniston, H. J. Gater, R. C. Rumbelow, J. W. Watson.

Midwifery.—E. F. Beaumont, W. M. Emmerson, H. J. May, A. Rogers, J. E. Turler, T. R. Waltenberg.

The L.S.A. Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery :—R. Appleton, W. T. Harris, A. R. Henchley, A. Mooney, and M. S. F. Scharlieb.

Conjoint Examinations in Ireland.

THE following candidates have passed the Final and Second Professional Examinations as undernoted :—

Final—A. Honours :—C. W. Ewing. B. Pass :—Miss L. H. Alexander, J. E. Brereton, J. B. Logan, J. P. O'Donnell, W. H. Mac M. Phelan.

Second Professional.—A. Honours (in order of merit):—W. W. Boyce, T. J. Madden, Miss C. E. O'Meara, equal ; R. Bury, A. C. Adams, M. J. C. Kennedy, R. A. Browne, J. M. Hayes, equal ; H. Hosty, I. Allann, H. N. Cole, J. S. Dunne, equal ; W. T. Morton. B. Pass—Alphabetically :—M. Ambrose, C. J. R. Clarke, P. E. Hayden, P. M. Moore, W. J. O'Donnell, H. E. Redmond.

Bequest to King's College Hospital.

UNDER the will of the late Mr. Robert Reeves Storke this institution is expected to benefit to the extent of £60,000.

REGISTERED FOR TRANSMISSION ABROAD.

"SALUS POPULI SUPREMA LEX,"

WEDNESDAY, FEBRUARY 4, 1903.

THE RECENT ASYLUM FIRE TRAGEDY

IN the early part of last week the London County Council's lunatic asylum at Colney Hatch was overtaken with a disaster unparalleled in the history of the United Kingdom, although it has been equalled or surpassed in the United States of America. The fire took place in a temporary building erected about seven years ago, and capable of accommodating some three hundred and fifty persons. It broke out at half past five in the morning at one end of the annexe in question. Under the influence of a high wind it quickly consumed the whole building, which was one storied and constructed of timber, match-boarded, and corrugated iron. The general arrangement of the annexe was that of five parallel wards connected by a central corridor. Each of the wards held about sixty patients, all of them women, and each had a separate exit. Altogether, at the moment of the outbreak, the roof of the annexe sheltered about three hundred and thirty persons all told, including nurses and attendants. Of these three hundred and thirty occupants within half an hour of the first appearance of the flames, two hundred and seventy-nine were in safety, while the remaining fifty-one, all female inmates, were killed. The asylum and district brigades were quickly in attendance, and it is officially stated that there was an abundant supply of water. The individual heroism of medical officers, nurses, and attendants in the rescue of patients was conspicuous, a fact we are glad to mention as the one cheering feature in this terrible tragedy. The annexe was connected with the main building by a corridor, also constructed of wood and iron, but the fire was fortunately prevented from spreading to the larger building. The main question that now arises is, how to prevent similar occurrences in the future. With regard to

the danger of fires in hospitals and asylums we ventured to predict in our issue of November 12th, 1902, that a great disaster would sooner or later overtake one of these institutions in the United Kingdom. Then, and not till then, might we hope that steps would be taken to secure as far as possible the safety of hospital and asylum patients from the terrible risks of fire. So far as our great hospitals, infirmaries, and asylums are concerned, we venture to say there is hardly a single one in the whole Kingdom constructed on modern principles with a view to the exclusion or prevention of fire. Some of our great London hospitals are built in such a way as to constitute one vast death-trap in the event of fire. Surely, if it be right for the County Council to control the construction of theatres, it would be far more necessary for them to look after the security of institutions peopled day and night by a helpless resident population. At the very least, they might be empowered to enforce the construction of such buildings in isolated blocks, and thus reduce the limits of a fire by an obvious and elementary precaution. At this very moment, however, two great London hospitals are extending their buildings without, so far as we can ascertain, the least regard for the limitation of the spread of possible fires. The inevitable consequence will be that some day or other the public will be startled with the news of an appalling holocaust in a hospital, infirmary, or asylum, of which the Colney Hatch tragedy may be taken as a type and a warning. Where it would perhaps be impossible to make buildings fire-proof, it is nevertheless feasible vastly to multiply the security of inmates against fire by the use of fire-resisting materials and fire-limiting construction, together with proper structural exits and well-organised means of fire extinction. How many of our great hospitals in any part of the Kingdom are properly equipped in these matters? From a somewhat wide experience we can testify that not a few of them are practically devoid of the most elementary appliances, and even of proper telephonic or other means of summoning the fire brigades in case of need. At Colney Hatch the annexe was built of most inflammable materials which we have no hesitation to say should not be countenanced in any building used for housing patients, least of all those who by the circumstances of the case, have to be kept under lock and key. The County Council, to our certain knowledge, have similar matchwood buildings at other asylums under their care, and it is to be hoped that steps will be taken forthwith to replace them by more stable structures. In future the Commissioners of Lunacy are not likely to license any more makeshift structures of the kind that were permitted to pass the ordeal of their inspection at Colney Hatch. Following within a few months time of the fatal fire in the City of London the present asylum tragedy may reasonably impress his Majesty's Government with the necessity of a general inquiry into the question of fire prevention as applied to all institutions, public and private, used for the reception of patients within the limits of the United Kingdom.

COMPARATIVE STATISTICS OF MORTALITY AMONG SOLDIERS.

THE contrast between the mortality in the French as compared with the German army, recently published by the *Gazette de Cologne*, showing as it does that the former is four times in excess of the latter, has not unnaturally given rise to much searching of heart. There must obviously be something radically wrong in the sanitary and hygienic arrangements of an army for the mortality to reach 17 per thousand men, while in that of a neighbouring country it only attains 1·4 per thousand. The figures, of course, only bear on deaths from disease. One explanation of the smaller mortality in the German army is that the supply of recruits being in excess of requirements, the weaker ones are not incorporated in the regiments. It follows that the average standard of health in the German army is, *pro tanto*, higher than in the French. The influence of this factor is the greater because the French have to strain every nerve to enlist an equal number of men, even after the Germans have eliminated 9 per cent. of the physically unfit. It follows that a comparatively low standard is all that can be insisted upon in the French army with results which are portrayed in the mortality returns. Moreover, in the German army, the moment a soldier's health shows signs of deterioration his place can easily be supplied from the reserve; consequently, he does not remain to swell the mortality returns of the army. This source of error can be got rid of by comparing the number of deaths from such a disease as typhoid fever in one and the other army since the victims cannot be got rid of and the disease runs its course *sur place*. From this point of view the figures are even more damning for France, typhoid fever accounting for 625 deaths among French soldiers as compared with only 87 in the German army. Even scarlet fever is more fatal in the French army in the proportion of 96 to 16, while tuberculosis is responsible for 1,415, against 129 deaths on the other side of the Rhine. Since the mortality returns under consideration bear only on causes common to the military and the civil population alike, they may be taken as indicative of defective hygiene affecting the population in general, although the mortality among the military is from 6 to 9 per cent. greater from this cause than in civil life. The hardships and physical stress incidental to military training cannot be credited with any share in the production of this terrible mortality, moreover, they would in any event tell with equal force on both sides. Indeed, on scrutinising the returns we find that the minimum mortality coincides with the maximum fatigue, *i.e.*, the periods of the *grands manœuvres*, and the mortality is everywhere far higher in the sedentary branches of the army than in those on active service. This, however, may be due in part to the fact that the more sedentary posts are occupied by recruits who, for physical reasons, are not judged capable of supporting the strain of active military life. The statistics of the English army cannot usefully be contrasted with those of conscript

armies, for the simple reason that the selection is much more rigorous and the standard of hygiene is far and away superior to that of any European army. The lesson is, nevertheless, worth learning, for it teaches us that sanitary defects are, in the long run, more deadly than the most disastrous campaigns.

ALCOHOLIC EPILEPSY.

ALIENISTS, and indeed all who take an interest in the etiology of epilepsy, must notice how frequently alcoholic excess is assigned as a cause of the disease. From the earliest times it has been known that epilepsy may be caused by alcoholic excess; but, it is a strange fact that in the past when such heavy drinking was common in every class of society, alcoholic epilepsy was seldom met with. Visceral complaints followed excesses, but epilepsy was seldom met with. Even more remarkable is the fact that in Southern Europe the disease is seldom met with, and in Southern France, Spain, and Italy, alcoholic epilepsy is practically unknown. Even the gin-drinking Dutchman escapes it. In countries that are almost, if not altogether, free from the disease, the wines, beers, and alcoholic drinks generally consumed are not heavily taxed, and as a rule are well matured, wholesome products of the grain or the grape. The heavy drinkers of the past consumed such liquors, and although they suffered visceral troubles from their excesses, epilepsy seldom followed. To-day the comparatively sober man becomes an epileptic. What is it that has changed the effects that the alcohol produces? We think the answer is to be found in the quality of the alcoholic drink of the day. The high duty on alcohol in the three kingdoms is a direct incentive to the production of alcohols from potatoes, beet-root, and treacle. These distillates are usually surreptitiously run and got rid of as quickly as possible at a cheap rate to some friendly vendor who mixes them with his stock, and corrects their nauseous flavour by artificial ethers. Sometimes, these raw spirits, sweetened and flavoured, find their way to the public as brandies or liqueurs. Come as they may, they are lethal in their effects. The price of pure alcoholic drink is almost prohibitive, and the difficulty is met by putting on the market doctored raw spirits that, as a rule, contain amylic and other alcohols, which in every sense of the word are toxins. In some instances, the toxic property of the liquid is diluted with silent spirit, as spirit which cannot fairly be included under either the name of whisky or brandy, and is not called for by the public, but manufactured specially for the publicans. The high duty levied on alcohol, by placing the matured old whiskies out of the reach of the people, indirectly fosters shebeening and the consumption of a poisonous drink, and this is too high a price to pay for revenue. Much might be done to check the production of these raw spirits by allowing a drink of low alcoholic strength to be produced at a lessened duty.

Notes on Current Topics.

The Pathology of Alcoholism.

IN the evolution of the race, alcohol has been and still is an influence of immense importance. Dr. Valpy French, in his valuable study on "Nineteen Centuries of Drink in England," has afforded abundant evidence of the moulding and modifying action of drinking habits on English life and character. Indulgence in alcoholic beverages is a procedure of great antiquity, and if we are to judge by the evidence of recent statistics, intemperance is likely long to remain as witness to human frailty. But during recent years there has been a remarkable growth of sentiment setting strongly in favour of restricting all agencies making for excessive indulgence in alcohol. The development of a strong public opinion on this matter has led to legislative action, which has secured measures rich in prophylactic and remedial possibilities. The coming into force of the new Licensing Act has focussed professional and popular attention on certain more conspicuous aspects of the alcohol question. Wide differences of opinion exist in regard to this matter. We are of opinion, however, that the awakening of a large section of the community to the dangers arising from the widespread alcoholisation of the people is due in great part to the increasing interest taken in hygienic matters. Medical men have for long insisted that the temperance question was fundamentally concerned with personal and public health. And it is manifest, we think, that if progress is to be maintained, it must be by a fair recognition of those scientific facts and experimental conclusions which recent investigation has rendered so clear and definite. Professor Sims Woodhead, of Cambridge, in a recent valuable essay on "The Pathology of Alcoholism," shows that the early morbid anatomists belonged to the school of the pessimistic physicians; they recognised the advanced morbid changes wrought by alcoholic excess, but until Virchow gave a new bent to the methods and observations of pathologists, the minor changes of function and structure were almost entirely overlooked. We now know that the history of a diseased cell can only be written when the most advanced pathological conditions can be traced back to the normal through the comparatively insignificant phases of deranged function and altered structure. Experimenters have followed the modern method in regard to alcohol with the result that it is now possible to demonstrate the deteriorating effect of even minute doses of alcohol upon healthy protoplasm; and in the case of the higher cells of the nervous system it is even possible to graphically record slight degrees of degradation of function. If the alcohol problem is to be solved, we believe it will be by a clear recognition and acceptance of the conclusions of pathological and psychological research. But there is still much to be made clear, and need for patient, unprejudiced investigation. We have gone far, however, in basing reform on a sound foundation of scientific precision.

A New Rest Cure.

THE "rest cure" is in the air at present, and many and varied are the forms it takes. Certainly one of the newest is that of careering across the Atlantic in midwinter. This does not sound conspicuously restful; but modern developments in shipbuilding seem to be popularising the winter ocean trip in the Atlantic as a remedy for the complaint popularly known as "run-down." The largest steamers in the world are the Atlantic "ferries" and the keen competition among the different lines sets a standard of luxury unknown on any other sea. A hospital nurse who lately crossed to Boston and back in a fourteen-thousand-ton liner (the Cunard "Saxonia," twin ship to the "Ivernia") was particularly struck with the effects of the voyage upon some of the passengers who were suffering from various forms of nervous trouble, generally accompanied by insomnia. These ships are not among the fastest of the line, taking about eight days from Liverpool to Boston, so that there was time to observe the effects of the voyage; moreover the question was not complicated by seasickness, as the "Saxonia" and "Ivernia" never develop motion enough to have the "fiddles" or storm-racks laid on the tables. The cold was by no means as trying as that on land, the air being extremely bracing and pure, so that most of the passengers were oftener on deck than in the warm saloons and libraries. The invalids in a day or two found themselves able to sleep with an unbroken profoundness only known at sea, and appetites increased with every meal. On ships of this magnitude, golf, cricket, and many other active games can be played at almost any time, and they are to be decidedly recommended, from a health point of view, to all who feel equal to the exertion. A warning against over-eating is necessary, as the keenness of an ocean appetite is not always the safest guide in the case of a traveller voyaging to recover health; and the number of meals served on liners of this class may be considered rather elaborate and excessive, from a medical point of view. On the whole, the North Atlantic "cure" seems to be surprisingly effective and rapid. The almost surgical purity of the atmosphere has probably much to do with this; the absolute freedom from worries of the land a good deal also, but the air is really the main thing. It is concentrated life and energy; there is nothing on land to compare with it.

The Treatment of Typhoid Fever by Bilberry.

MANY and varied attempts have been made to cope with the specific cause of typhoid fever by means of intestinal antiseptics. They aim at introducing into the intestines bactericidal agents in such form and of sufficient strength as to destroy the typhoid bacilli, or, at least, to arrest their development and stay their dissemination. The search for a convenient and effective disinfectant or antiseptic has been arduous, and in the course of the quest the praises of many bodies have been loudly proclaimed. Chlorine water, salol, naph-

thalin, *A*-naphthol and *B*-naphthol, iodoform, calomel, and others, either in simple substance or more or less complex combination, have been employed. And now Dr. Bernstein, at the last meeting of the Hunterian Society, sings the praises of the common bilberry. His evidence, both clinical and bacteriological, is by no means convincing, but the result of his experiments, at least those carried out according to laboratory methods, seems to indicate that bilberries have as much right to be considered an intestinal antiseptic as many much advertised substances. But it is necessary to exercise much caution in drawing any conclusions from the results of investigations concerning the action of drugs. There is no doubt that the conditions *in vitro* are not comparable with those prevailing in the intestinal canal of the living subject. We certainly think that at present it is wisest to assume a doubtful attitude towards the treatment of typhoid fever by antiseptics. And we are sceptical as to the likelihood of any such being ever available. It must be remembered that typhoid fever must be considered a general disease. The organisms have been found in all parts of the body, and even isolated from the rose spots, and hence to focus attention on the intestinal tract is to take a very restricted view. It is, of course, quite possible that some of these so-called intestinal antiseptics may sometimes be of some benefit in lessening or even arresting fermentative changes, but there is certainly no satisfactory evidence that they are of any service in destroying the typhoid bacillus in the body, and hence to claim for bilberry or any other substances specific virtues is to hinder rather than hasten the adoption of rational procedures in the management of this all too common infectious disease.

Psychical Research.

MEDICAL men have numerous and peculiar opportunities for making excursions into mental, psychological, and psychical regions. To these Sir Oliver Lodge's brilliant presidential discourse to the Society for Psychical Research will open up many new paths deserving of exploration. Principal Lodge, as a distinguished physicist, approaches psychical investigation in the truly scientific spirit, and seeks to imbue all workers with a like incentive. Sir Oliver, at last Friday's meeting, was able to present ample evidence of the seriousness in which he approaches the perplexing problems connected with psychical research, for he announced that an endowment fund had been started which already amounted to £2,000; and it is proposed, as soon as a capital sum of £8,000 has been attained, to offer a research scholarship in psychical science, the holder being elected irrespective of sex or nationality, and devoting his or her time to the work of psychical investigation. Although so-called psychical manifestations are viewed askance by many, and not a few prejudiced and shallow minds seek delight in vulgar scoffing, there seems no good reason to deny the possible utility of such studies as Sir Oliver Lodge desires should be carried out, and we are glad to see that there is a possi-

bility of subjecting many points now in dispute to careful experimental investigation.

The Mental Borderland.

THE borderlands are ever the battlefields, be they territorial, moral, or intellectual. The lawyer and the physician are constantly disputing regarding boundaries, limitations, and definitions. The Lunacy Act recognises the lunatic as being a person of unsound mind, which, of course, is perfectly correct; but, unfortunately, the Commissioners and lawyers generally are slow to recognise that the reverse proposition is not necessarily correct, and that everybody of unsound mind is not a lunatic. Dr. G. H. Savage insists on the fact that much is needed before our lunacy legislation will even approximate perfection. It is not to be expected that the definitions of lawyers and doctors will ever agree. The former are always hankering after a "sign" while the latter insist on denying the application of a hard and fast definition of insanity. Insanity is peculiarly a relative condition, so that what is sane in one man is insane in the conduct of another, and what may be sane at one period of our lives would be insane at another. Insanity always connotes unsoundness of mind, but unsoundness of mind certainly does not connote legal insanity. The sooner this fact is realised by those responsible for the carrying out of the law the better for the patients and the better for those who care for them.

The Constitutionally Unemployed.

PUBLIC attention is largely occupied just now with the problem of relieving the distress of the unemployed, and we note everywhere a desire to distinguish as far as possible between the "genuine unemployed" and the large proportion of poor who are mentally or physically incapacitated for steady work. From both the social and medical points of view, the latter are a much more interesting class than workmen who are merely "out of a job." To be born with a rooted distaste for honest work or with a constitutional incapacity for physical exertion, is obviously a much more serious matter than to be temporarily unable to find work to do. In the former case the evil is ephemeral, whereas in the latter it renders the afflicted useless members of the community. We may leave it to the State and to municipalities to cope with the problem of finding work for the unemployed of the able-bodied, willing class, but it would be folly to persist in ignoring the grave problem of how to deal with the other class. These are always with us, be the state of the industrial market what it may. They furnish a large contingent to the criminal classes from sheer inability to live by honest means. To deal fairly by them we are constrained to regard a chronic indisposition to work as a mild form of mental aberration closely allied to physical enfeeblement, and calling for special measures. Apparently the only way of eliminating this distressful class from our urban population would be by the formation of industrial colonies, but the technical difficulties in the way

of organising such colonies by any process of selection are enormous, and have so far paralysed the efforts of philanthropic individuals in that direction. Still, something of the kind must sooner or later be attempted, and the dreary processions which have of late cast a gloomy shadow over the thoroughfares of the Metropolis are serving the purpose of bringing home to the more fortunate and better gifted the terrible element of danger which lurks more or less unperceived in these aggregations of the unfit. Our duty as Christians is to strive to relieve the wretchedness of the *debiles* and our interest as members of the body politic should impel us to take steps to educate, train, and, if necessary, maintain, those who are unfitted to play a useful part in the struggle for existence by physical or intellectual incapacity.

The Colour Cure of Insanity.

THIS cure was tried as far back as 1897, and Dr. Monette, at Ward's Island Asylum, is using it now for insanity. Only the primary colours are employed, and the patient is so surrounded by an atmosphere of that particular colour deemed best by the physician for his particular case that its vibrations act upon him. The walls, furniture, and shades of a room are painted a certain colour, so that the patient is submerged in the one colour. Black and complete silence are employed for those suffering from acute mania, red is employed when melancholia is being treated (everyone knows the cheering effect of red). Then there are violet rooms for the milder forms of insanity, blue and green rooms for the boisterous, and white for those who are most normal. The patient is treated in three grades of colour rooms, and the result is said to be most beneficial. It is also being used for nervous prostration by some American doctors. Our asylums would soon cease to be overcrowded if the heads of them could be brought to believe that the upholsterer and paperhanger are the chief factors in what would certainly be a cheap cure.

The International Medical Press Association.

WE publish elsewhere a letter from the chairman of the provisional committee of the British Medical Press Association, calling attention to the formation of an association of the British medical press to co-operate with the international committee in bringing about a really international organisation of those engaged in medical literary work. The proposal was first mooted at the International Medical Congress at Rome, but the first steps in the direction of organisation were not taken until the Congress in Paris in 1900, consequent upon which twenty-eight delegates met at Monaco in April last at the invitation of the Prince of Monaco to discuss the rules or statutes of the proposed association. After considerable discussion certain principles were agreed upon to serve as the basis of organisation. In all cases it is the scientific and literary side, and not the commercial aspect, of medical journalism that is to be represented at, and form part of, the international association.

The members will be required to undertake to respect the conventions for the protection of literary copyright, to facilitate exchanges of publications and to pay their subscriptions to the international treasurer. For the current year the subscription per nationality only amounts to sixty francs. The Association is governed by a permanent committee consisting of the members present at the Monaco conference, subject to re-election at each general assembly which will take place shortly before each international medical congress. It is hoped by this means to obtain that medical journalists shall no longer be isolated individuals, but will have an international and representative organisation, from which they can obtain assistance when required, and the adhesion of all who are interested in medical journalism is invited with this object in view.

The Fee for Public Vaccination at Home.

A FEE of seven shillings and sixpence for vaccinating a child at his own home cannot be considered exorbitant in view of the trouble which such domiciliary visits entail, but a very wide construction has been placed on the term "home," and it has become necessary to define with more precision exactly what it is intended to convey. The question came to the front the other day at Kingston-on-Thames, where the amount of the public vaccinator's bill was challenged by a local ratepayers' association, and the Government auditor's attention was drawn to the scale of fees charged in respect of a number of men employed at the waterworks who had been vaccinated on the premises. These had been charged as home vaccinations, but the auditor held that the lower scale of fees, viz., half a crown, was payable when the person was vaccinated at the vaccinator's surgery "or elsewhere than at the patient's home," consequently the charges would have to be modified accordingly. There may be special circumstances under which vaccinations carried out on private premises, other than the public vaccinator's residence, ought to be paid for at the higher rate, but, as a general rule, it must be conceded that vaccinations *en masse* performed at factories are adequately remunerated by the lower fee. In the absence of a decision, however, it was only natural that the higher fee should have been asked, and, as matters stand, it is not unlikely that the auditor's dictum may be challenged.

Toxic Resistance to Anæsthesia.

EVERY anæsthetist is aware of the fact that the induction of anæsthesia in persons addicted to the abuse of alcohol presents special difficulty. The habitual ingestion of alcohol in excess appears to induce a condition of the nervous system which renders it more or less refractory to the influence of most anæsthetics, the stage of excitement being unduly marked and prolonged. Dr. Hewitt points out that over-indulgence in tobacco determines a very similar state, and in some instances these two vices, associated as they so frequently are,

render the subject virtually refractory to the induction of anæsthesia. These are factors which have to be reckoned with in anæsthetic practice, and if the subject were closely investigated there is little doubt that accidental toxic conditions of this sort would be found to be responsible for a tolerably large proportion of the accidents under anæsthetics. It is worth noting that the resistance thus developed is not limited to any one anæsthetic but extends to them all—nitrous oxide, ether and chloroform alike, so that an alcoholic subject, in addition to the diseases specially predisposed to by his habit, comes on the operating table under circumstances vastly less favourable than the average surgical patient.

• Is Appendicitis in Fashion ?

THE editors of medical journals do not lay claim to the prophetic instinct more than their fellows of the lay Press, but the editor of the *Journal of the American Medical Association* ventured some time ago to foretell that the fact of the King having been operated upon for appendicitis would lead to a "boom" in this department of surgery. In a number recently to hand he claims, on what appears to us to be very slender grounds, to have obtained the realisation of his prophecy. They may be better informed in America than we are here, but we are not in possession of any information which would lead us to suppose that such operations have of late increased in frequency. Even if they had the inference that would suggest itself is that the courageous example of his Majesty may have induced the victims of this lesion to submit more readily to the only effectual remedy than was the case previously. The fact that appendicitis is now very common, whereas a quarter of a century ago it was unknown, is evidence merely of improved diagnosis, and, as a corollary, more accurate nomenclature. Under the circumstances we must with regret refuse the gift of prophecy to our contemporary.

The Pathogenesis of Puerperal Insanity.

THE possibility that the peculiar form of insanity which develops in connection with labour and the puerperium may be due to the presence of toxins in the blood of the victim has received a certain amount of attention of late years, but the hypothesis does not appear to repose on any serious scientific basis. It has not been shown that puerperal insanity is essentially different from forms of mental aberration which develop under other conditions in the absence of puerperal stimuli. There is, on the other hand, every reason to believe that the puerperal state is merely the accidental excitant which reveals a lack of mental equilibrium, it may be, previously unsuspected. Nevertheless, an investigation into the personal and family antecedents of the victims almost invariably demonstrates a constitutional predisposition to mental instability, and this is, after all, what one would expect. Under these circumstances it can hardly be a question of its prevention, and our interest is concentrated on its diagnosis

and treatment. With regard to treatment there can be no room for difference of opinion as to the extreme importance of placing the victims of puerperal insanity in special institutions, the irritating effect of the normal environment being one of the most salient features of these attacks. The diagnosis is by no means easy, that is to say, the conscientious practitioner is often at a loss to define the exact degree of mental instability which would justify sequestration, and he is consequently prone to adopt an expectant attitude which opens wide the door to disastrous eventualities. Our knowledge in this respect has not been markedly increased in spite of the attention the subject has received. Failure of appetite and sleeplessness must still be regarded as the principal warning symptoms which ought to place the practitioner on his guard, and in presence of these premonitory symptoms it behoves him to take steps, short of instant removal, to secure the safety of his patient and of the child.

Annual Dinner of the British Gynæcological Society.

SIR JOHN HALLIDAY CROOM (President of the Royal College of Surgeons, Edinburgh) occupied the chair at the annual dinner of the British Gynæcological Society, held on Thursday last, at the Café Monico, London. The usual loyal toasts having been honoured with due ceremony, and Dr. Clement Godson having proposed the toast of "The Visitors," in which he complimented the ladies, who were present in considerable numbers, Dr. Eden utilised the opportunity of his replying to the toast by relating how his old teacher, Sir John Halliday Croom, used to delight his students with aphorisms that lived in the memory of all who heard them. The President of the North of England Obstetrical and Gynæcological Society (Dr. S. Buckley) gave the toast of "The Society." The attractions, he said, to attend the Society's meetings were threefold: imparting knowledge, gaining knowledge, and the promotion of good fellowship. Sir John Halliday Croom, in replying, delighted his audience with a witty and humorous speech. Dr. Macnaughton-Jones next gave the toast of "Universities and Medical Corporations," in which he expressed regret that the Queen's University in Cork had ceased to exist. He proudly declared that the Queen's University in its thirty years of life had trained as many famous servants of the State as any University in the Kingdom, and he named the late Sir William MacCormac as a brilliant example of the type of man Cork University had produced. He evidently was voicing the opinions of his audience when he eloquently delivered himself of the opinion that a University that was a mere examining board could never become a real University capable of developing character in its graduates. Mr. W. Parson (Master of the Society of Apothecaries of London) and Dr. F. F. Schacht having responded to the toast, were followed by Dr. Heywood Smith, who gave the "Sister Societies." This was duly acknowledged by Mr. Howard

Marsh (President of the Clinical Society of London). A very excellent programme of music contributed greatly to the enjoyment of the evening, and much praise is due to the efforts of the hon. secretaries, which resulted in such a successful function.

Mr. Troutbeck Again to the Fore.

THE ways of Mr. Troutbeck are past understanding. On his own showing the services of Dr. Freyberger, erroneously described as pathologist to the London County Council, were only to be requisitioned in "special cases," but Mr. Troutbeck's notions of special circumstances are exceedingly elastic and vary accordingly. At an inquest held last week on the body of an infant, who, it was suggested, had succumbed to the effects of improper feeding, he confided the post-mortem examination to his pathological acolyte instead of asking the medical man in attendance to fulfil this task. He was good enough to intimate to the practitioner that he might attend as a witness, but was rewarded by what he described as a very impertinent letter "protesting against his (the coroner's) action in not calling him in to be a judge of his own case." Mr. Troutbeck enlisted the sympathy of his jury by insisting on the extreme importance of obtaining unprejudiced evidence, thereby implying very clearly that the practitioner's evidence would not have been unbiassed. This is only another instance of Mr. Troutbeck's willingness to cast aspersions, utterly unwarranted by facts, on medical evidence, and is not unlikely to lead to further developments. It would be absurd to pretend that Mr. Troutbeck's reckless remarks threaten the honour of the profession, but they are certainly calculated to give rise to a most undesirable amount of friction.

Indian Army Anecdotes.

AN interesting article on some former worthies of the Indian Medical Service appears in the current number of the *Navy and Army*. The serious aspects of the service are left untouched and the writer devotes himself to several pleasant anecdotes of medical men he has met during a long stay in India. He starts by noting the decease of that Dr. "Dado" to whom Sir William Hooper referred in his address to the Lieutenants of the Indian Medical Service at Netley a short time ago. Dr. "Dado" was devoted to a certain reliable pill of his own composition, and in his hospital rounds was invariably accompanied by an orderly who carried a box of them. The doctor gravely listened to each sufferer, but no matter what the complaint, his remedy was similar. The summary of woes over he would turn to the orderly—"Dado" (*Hindustani give*), and the treatment of the case was complete. The writer has a kind word for most of those whom he mentions. Surgeon-General Sir Anthony Home, V.C., even though he and Lady Home not infrequently confronted their callers with an intimation that "they did not desire to extend the circle of their acquaintance," still had "heaps of professional enthusiasm," and was the most

retiring man the writer ever met. As a contrast to Sir Anthony, the story of an Irish medical man is told who took it into his head to chaff a visitor, a major in a native infantry regiment, on being an "impartial rider"—"impartial as to what part of the animal ye ride on," and whose chagrin was deep on learning that his victim was one of the best steeplechasers in India. Captain Wheeler's article will doubtless recall pleasant memories of old times to many of his readers.

The Resignation of Mr. Austin Meldon.

THE resignation of the Surgeoncy of Jervis Street Hospital by Mr. Austin Meldon has been received with much regret by the managing committee. Mr. Meldon has held the position since 1867, and during this period had been the recipient of many honours. He was president of the Royal College of Surgeons on more than one occasion, President of the Irish Medical Association, and a D.L. for County Dublin. He still holds the Consulting Surgeoncy of several institutions. His former colleagues on the Medical Board at Jervis Street Hospital, on learning of his resignation, unanimously resolved: "That the medical staff of Jervis Street Hospital do place on record their profound regret at the resignation of Doctor Meldon, D.L., and their warm appreciation of his services to the hospital and his colleagues through a long series of years." Mr. Meldon has been succeeded by Dr. Edward Stapleton.

A Hospital Without Water.

UNDER the above heading, the general newspaper Press has been flooded with descriptions of the circumstances attending a temporary failure of the water supply at a special hospital in South London. Proceedings at a local police court have not been successful in obtaining redress from the water company concerned, who successfully pleaded the influence of circumstances outside their control. It is questionable, however, whether their statutory obligations towards consumers would be dismissed with such apparent lightness in the higher courts. The police court proceedings, however, were peculiar in that the complainant was the senior surgeon of the special hospital in question, a gentleman who is also professor of ophthalmology in a leading school. His name and titles have been blazoned forth wholesale in the public newspapers in a way that must be most offensive not only to himself but also to his colleagues. We would suggest that the proper person to conduct police court proceedings on behalf of a hospital is the secretary, and not one of the honorary staff, who may by courtesy be supposed to be far too busy to run the chance of wasting many precious hours in a police court.

St. Bartholomew's Hospital.

THE mass of pointed criticism raised by the appeal for an extension fund on the part of the authorities of St. Bartholomew's Hospital has not been without its far-reaching effects. While the executive of that ancient charity denounced their

critics in unmeasured terms as ill-informed and hostile, they have nevertheless so far bowed to the storm as to appoint a special committee to consider the feasibility of changing the site of the Hospital. So far as can be judged, the composition of the committee is hardly wide enough to ensure a thoroughly independent and unbiassed report. In making that remark there is no intention whatever of reflecting on the individual honour and integrity of the distinguished gentlemen whose names appear on the committee in question. The issues at stake, however, are so great as to make it desirable in the interests both of the public and of the medical profession that they should be investigated by a body as far as possible representative of all important outside views. The great distributing funds, the other large hospitals, the City Corporation, the London County Council, the medical journals, the British Medical Association, the Medical Defence Union, and many other lay and professional bodies might not unreasonably claim a voice in the matter. In approaching the question of the decentralisation of hospitals, it is important that executive committees of these charities should bear in mind that they are the trustees of funds which it is their imperative duty to administer to the best advantage of the community at large. Any strong board of inquiry should secure the services of some legal luminary learned in the practical handling of evidence.

Unnecessary Heroism.

THE occurrence of a case of typhoid fever in the rural district of Stafford gave rise last week to a discussion as to the probable source of infection. Infection by oysters being *à la mode*, certain bivalves which the patient had eaten were incriminated, but Dr. S. Butler, the medical officer of health, discredited this view, and on visiting the shop whence the oysters had been procured himself ate a score thereof, thus conclusively (?) demonstrating their freedom from contamination. The example is not one which we can commend, for, if followed, many valuable lives would be quite unnecessarily sacrificed on the altar of science. Moreover, the test is notoriously fallacious, first because non-infection is no proof of non-infectivity, and, secondly, because the non-infectivity of one plate of oysters by no means demonstrates the innocuousness of a previous batch. The duties of medical officers of health include risks enough when carried out in accordance with precedent, and additions thereto are to be deprecated.

An Anti-Echinococcal Serum.

THE echinococcus does not belong to the group of parasites against which preventive or seropathic injections have hitherto given any noteworthy results, but Dr. F. Dévé, of Paris, has sought to turn to useful account the curious immunity of the guinea pig against inoculations with the scolex. After a number of experiments he states that he has succeeded in rendering a rabbit immune to such inoculations by injections of guinea pig serum, the rabbit usually being very susceptible to

infection. The experiment resembles too closely the attempt to confer immunity against tuberculosis by means of injections of goat serum for it to command ready acceptance; moreover, echinococcal infection is, under ordinary circumstances, such an infinitesimal risk that merely preventive measures possess at most a scientific interest.

Sleepy Railway Travellers.

THE ways of the average British railway traveller are certainly such as to suggest a lethargic nature to a casual observer. Whether by day or by night, it is his custom, if the journey be reckoned in anything beyond minutes, to close his eyes and nod his head and mimic, even if he doth not achieve the outward pose of slumber. For all that it may be taken as a fact that in most cases he is simply performing the essentially old-fashioned insular trick figuratively known as "sleeping with one eye open." The reasons that lead to slumber or its reposeful counterfeit on the part of the British day traveller are most likely of a complex nature. The conditions of railway travelling are not, as a rule, favourable to reading, especially if the traveller suffer from any abnormality of vision, however slight. The alternative of focussing one's eyes on the opposite side of the carriage or upon a row of uninteresting fellow travellers soon becomes irksome, and a ready escape therefrom is often afforded by the mere closing of the eyelids. Besides, the faculty of commanding slumber amid unfavourable surroundings may perhaps be regarded as an outward sign of the solidity of the national temperament. To sleep at any moment is undoubtedly a sign of physical soundness and Philistine sanity, especially in the matter of the brain and its functions. A physician would have little anxiety about the general condition of a patient who could sleep at will on a railway journey. In these days of hurry and bustle there could be no more encouraging sight to the philosopher than a railway carriage at noonday full of sleepy passengers.

THE eleventh International Congress of Hygiene and Demography will be held in Brussels from the 2nd to the 8th of September next, under the patronage of the King of the Belgians. The Secretary-General of the Congress is Professor Dr. F. Putzeys. All information and programmes can be obtained from Dr. Paul F. Moline, 42, Walton Street, Chelsea, S.W., the Hon. Secretary of the British Committee.

PERSONAL.

DR. H. RADCLIFFE CROCKER will deliver the Lettsomian Lectures of the Medical Society of London, beginning on February 16th.

SIR HENRY G. HOWSE, President of the Royal College of Surgeons of England, will deliver the Hunterian Oration on Saturday, February 14th.

PROFESSOR E. VON BERGMANN has been elected President of the Berlin Medical Society, in succession to the late Professor Virchow.

DR. T. G. BRODIE has been appointed Professor Superintendent of the Brown Animal Sanatory Institution, in succession to Dr. J. Rose Bradford, F.R.S.

LORD ROBERTS is to be admitted to the Honorary Fellowship of the Royal College of Surgeons of England at the Hunterian Festival Dinner on February 14th.

PROFESSOR DANIEL CUNNINGHAM is mentioned as the probable successor to Sir William Turner in the chair of anatomy at the University of Edinburgh.

SIR WILLIAM CHURCH, President of the Royal College of Physicians, has promised to preside on Wednesday, March 4th, at the annual meeting of the After Care Association for Poor Persons Discharged Recovered from Asylums for the Insane.

DR. A. S. F. GRUNBAUM has been appointed director of the Institute for Cancer Research so largely due to the munificence of Mr. Sutton Timmis, of Liverpool. The work is to be carried on in connection with the University College and the Royal Infirmary.

MR. EDWARD FITZGERALD STAPLETON, M.D., has been elected Surgeon to Jervis Street Hospital, Dublin, to fill the place rendered vacant by the resignation of Mr. Austin Meldon, F.R.C.S., D.L., to which we have referred in another column.

SIR WILLIAM TURNER, K.C.B., F.R.C.S., F.R.S., the new Principal of Edinburgh University, was formally inducted on January 31st, at a meeting of the Senatus. The proceedings were private. Professor Crum Brown, as Senior Professor, presided, and Professor Chrystal, as Senior Dean, presented the new Principal to the President. The formal ceremony having been completed by Professor Sir Ludovic Grant, Secretary to the Senatus, reading the commission appointing Sir William Turner to the Principalship, his late colleagues in the Professoriate cordially welcomed their new Principal.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

ENDOWMENT OF RESEARCH BY THE CARNEGIE TRUST.—It is reported that the trustees, having dealt with the two primary objects for which the fund was instituted—the payment of fees, and the better equipment of the universities in matters connected with teaching—have now under consideration what is a necessary corollary and extension of the second of these objects—the endowment of scientific research. It will be remembered that after providing for some of the demands made by the universities, the trustees still retained in their hands a part of the income of the trust, and it is to be presumed that some of this, at least, will be devoted to endowing original workers. According to the London correspondent of the *Scotsman*, who is seldom incorrectly informed, the project of the executive committee will probably be approved by the general body of the trustees, and will be made public during the present month. It is not intended to create Fellowships, which will be a source of maintenance to the fortunate holders, but rather to make grants which, while sufficient for adequate study, are not so large as to tempt the possessors to cling to them for a livelihood. Carnegie Fellows will not be selected by competitive examination, but will be chosen by the trustees, so that

these Fellowships will in no way compare with the majority of other university awards. The candidates will have to show their university record, and state the work they propose to pursue. The conditions of granting the endowments will be as little rigid as possible, and subject to the periodical reports which the Fellows hand in being satisfactory, the fullest liberty will be given as to where the research is to be carried out. A second and minor class of scholarships is also contemplated, the holders of which will be graduates connected with the university classes. It will be a matter for regret if, as stated, the extramural schools do not participate in the scheme, though no doubt most of the students of these schools intend graduating at the universities, and so will be eligible for election to a Fellowship.

In regard to the security of the Carnegie Fund, it should be recollected that though fluctuations may occur in the Steel Trust stocks, the endowment consists of debentures, which are never publicly offered, and are secured on great blocks of property.

OVERCROWDING OF EDINBURGH POORHOUSE HOSPITALS.—This question came before the Parish Council recently on the receipt of communications from the Local Government Board, and it was ultimately decided to provide additional buildings at Craiglockhart for the accommodation of pauper patients. The mover of the motion which became the finding of the committee approved generally of the plan of having temporary wood and iron structures instead of permanent stone buildings. In the discussion it appeared that numerous phthisical patients were distributed among the general wards because there was not space for all in the ward reserved for such cases. One proposal, therefore, was that a separate building to accommodate forty or fifty phthisical cases should be provided, while another speaker advocated a children's ward. The only other suggestion in the way of obviating the difficulty was that many chronic patients should be sent to other poorhouses throughout the country.

PLAGUE OF RATS IN EDINBURGH.—It is stated that the business premises in Prince's Street are invested with rats, which have gained entry from the gardens opposite. The nuisance has increased greatly since a bank of ivy was planted some years ago on a terrace which slopes down from the street to the gardens. This ivy affords an excellent shelter and breeding place for the vermin, which burrow their way to a disused drain, and thence to the shops, hotels, and private houses opposite. The Corporation have been asked times and again to move in the matter, the remedy suggested being to remove the ivy and plant grass, but have shown no inclination to take any steps, while the sufferers are naturally averse to making their grievance public. Apart from the nuisance which the depredations of the animals create, the more remote dangers to which their presence in unchecked numbers may give cannot be denied, and it cannot be forgotten that only two years ago a large hotel in Glasgow had to be closed because of the occurrence in it of a series of cases of plague. Though, happily, such a thing is almost beyond the limits of possibility now, if it did occur the existence of this swarm of rats would greatly enhance the difficulty of checking it. It is, therefore, to be hoped that steps will soon be taken to avert what bids fair to become a public scandal.

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

BELFAST MATERNITY HOSPITAL.—An election was held last week for the post of senior physician, rendered vacant by the resignation of Dr. Brice Smyth. There were a large number of applicants for the post, to which Professor J. W. Byers was elected. It is said that the committee of the hospital, being anxious to strengthen their teaching staff, invited him to apply, so that his election was a foregone conclusion.

THE HOSIER GREEN CONSUMPTION HOSPITAL.—We regret to find that this excellent institution is not being as liberally supported as it should be, and from the report we learn that the year closed with the balance on the wrong side. Subscriptions from the City of Belfast are both numerous and large, but from the different Ulster counties, from which the hospital receives patients, there is no corresponding list of subscriptions. If the country gentlemen acted in the same generous spirit as the Belfast citizens, the support afforded would be sufficient to not only enable the full capacity of the building to be availed of, but it would enable the governors to enlarge the buildings and establish more beds. The value to the community of a sanatorium where incipient tuberculous cases could be sent is very great, both from a financial point of view and from a sanitary one. A healthy people make little demand on the taxpayer, in the ranks of commerce as in those of the army it is the sick and broken-down soldiers that run up the expense. The best friend of commercial industry is preventive medicine, and next to preventive measures are the sanatoria that restore the bread-winner to their families and homes.

Correspondence.

CORONERS AND POST-MORTEM EXAMINATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There is one reason which is in favour of the appointment of a pathologist by the London County Council which is not considered in your article of last week. I had opportunities of judging of it from the post-mortem work I took an interest in when Lecturer on Pathology and Forensic Medicine to the Westminster Hospital, and Mr. St. Clair Bedford was good enough to discuss the question of inquests with me. The reason I refer to is the risk that practitioners run when they have midwifery and surgical practice which requires care, and above all things, the avoidance of handling the dead body. It frequently occurred to me to be asked to share the £2 2s. fee in inquest cases, where my object was to have a subject for lectures to students and questions of forensic interest were involved. It appeared to me then that it would really be of advantage if a pathologist had the post-mortem to do, much as the analysis in poison cases is handed over to chemists.

I am, yours truly,

ROBERT LEE

39, Gunterstone Road, W., February 1st, 1903.

ASSOCIATION OF THE BRITISH MEDICAL PRESS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A proposal was made some time ago on behalf of the French medical press for the formation of an International Association of the medical press. A provisional committee was formed in this country under my chairmanship. This committee was represented at a conference held at Monaco in April, 1902, under the presidency of Professor Cornil to settle preliminary details. The regulations then adopted have recently reached this country and the provisions proposed seem on the whole expedient and reasonable. An association of the British Medical Press has therefore been formed to co-operate with the International Association.

The editor of any British journal devoted to medicine who may wish to join this association or desires further information on the subject should communicate with Mr. L. E. Creasy, Editor, *The Clinical Journal*, 35A, Welbeck Street, Cavendish Square, London, W.

I remain, Sir, yours faithfully,

THOMAS WAKLEY, JNR.,

Joint Editor of *The Lancet*.

January 27th, 1903.

Laboratory Notes.

ODIN VEGETABLE EXTRACT.

(Prepared by the ODIN SYNDICATE, LTD., 31, Eagle Wharf, New North Road, London, N.)

THIS preparation, which is purely a vegetable one, has a remarkable similarity—both in chemical composition and in its physical characters—to the best types of meat extract. We have had the opportunity of making a personal visit to the works where this article is prepared, and are able to testify to the care and scrupulous cleanliness observed in manufacture.

No preservative is employed, but the extract will be found to keep well even in tropical countries. Its high degree of concentration and consequent portability render it very suitable for expeditions, and the ease with which a palatable and nourishing soup may be prepared by its aid will render it invaluable to foreign travellers.

On analysis we have obtained the following results:—Moisture, 20.0; total solid matter, 80.0; mineral matter, 20.1; total nitrogenous matter, 37.0. The mineral matter was rich in phosphates.

From these figures it will be seen that it bears a strong resemblance in composition to the best meat extracts, and no doubt is equal to them in stimulating and nourishing qualities.

We can confidently recommend this preparation to our medical readers, by whom samples may be obtained on application to the makers.

Lunacy Department.

THE TREATMENT OF INCIPIENT INSANITY.

EDINBURGH Parish Council, at a recent meeting considered a report by the clerk on the observation wards in Barnhill Poorhouse, Glasgow, for the treatment of cases of incipient and temporary insanity, and came to the conclusion that there was no necessity meantime for altering their present arrangements.

Edinburgh Royal Infirmary treats such cases, while the Glasgow infirmaries do not, and this perhaps accounts for the Glasgow parochial authorities dealing with them.

While the number of Glasgow cases treated in the observation wards in the course of 1900 and 1901 amounted to 248 and 212 respectively, similar cases treated in the Royal Edinburgh Infirmary amounted to 337 and 316.

Out of all these cases in Edinburgh only 34 in each year were handed over to the parish and sent to the asylum, which demonstrates the success of this treatment of incipient insanity.

The method adopted by the Glasgow authorities saves the patient from the stigma of having been treated in an asylum, while the Edinburgh method goes one better, saving them also from the stigma of pauperism.

EDINBURGH LUNACY BOARD.

A MEETING of this Board was held on the 19th ult., and the proposal to construct five villas of wood and iron at Bangour, as recommended by the General Board of Lunacy, was again discussed. One member compared this step to putting "the cart before the horse," and referred to these buildings as "death traps," and thought the Board were taking the proper proceedings to reduce the number of lunatics.

He could not see the necessity for pushing the matter so quickly, thus displaying total ignorance of the true state of affairs, as there is every reason for all speed. His remarks were foolish with the exception of his reference to the material used in building being inflammable. Its nature is of a composite wood and iron character, and the interior covering is composed of a peculiar papier-maché composition, and there is no doubt the risk of fire is very great, especially with open fire-places. The asylum committee had visited the

Glasgow district asylums and inspected similar buildings recently constructed there, and were highly satisfied with the result of their visit.

We think the Board have decided wisely in resolving to erect this style of building, as the rapidity of its construction is a weighty essential, considering the unfortunate position into which they have brought themselves.

LUNACY IN NEW ZEALAND.

THE report of the Inspector-General for 1901 on the lunatic asylums of this colony is interesting and worthy of notice. It enlightens us as to the treatment of the insane in that country, and enables the statistician to compare the results with those obtained in this and other countries. The number of registered insane persons on December 31st, 1901, was 2,773, an increase of 101 over the previous year, and the proportion of the total insane to the total population was 3.34 per 1,000. The cause of insanity in 15 per cent. of the admissions was attributed to alcoholic excess, and to congenital and hereditary in 16 per cent. The percentage of deaths on the average number resident during the year was 6.41, as compared with 5.61 for the previous year. The table showing the causes of death presents nothing exceptional. In 14 and 12.6 per cent. of the cases respectively death was due to general paralysis and phthisis. The percentage of recoveries to admissions was 42.17, and this must be regarded as satisfactory. The average total cost per patient was £27 12s. The report includes reports by the various medical superintendents and entries of visits of the inspector to the different asylums, together with the usual statistical tables.

Auckland Asylum.—Dr. Beattie again draws attention to the urgent need for increased female accommodation. Unfortunately the asylum population consists of a very large number of female refractory patients, and the accommodation for this class is quite inadequate. The number of patients has increased from 487 to 515, and the admission rate continues high. The general health has been good, though four cases of typhoid fever occurred. A new male hospital wing has been opened. The inspector records his admiration for the results of Dr. Beattie's admirable energy and devotion.

Wellington.—During the year 107 patients have been admitted, and here also there is a cry against congested accommodation. The recovery rate is very satisfactory; of the males, 57.9 per cent. recovered, and 57.8 of the females. The percentage of death to admissions was about 15 over all. The question of morality and heredity, as it bears on insanity and criminality, has been forcibly thrust upon Dr. Gow by a case admitted, and the statement he gives concerning her antecedents and progeny reveals a moral depravity so disgusting that we are appalled. The State should provide a remedy for such cases. There has been a good deal of dissatisfaction and changing amongst the staff, attributable to agitation for shorter hours and improved wages.

Sunnyside.—In referring to the admissions the medical superintendent observes that this asylum has become a dumping-ground for defective troublesome children and old people in their dotage, and that a very large proportion of the admissions are most unfavourable as regards recovery, rendering the asylum more of an almshouse than a hospital for the insane. This abuse, he also says, is becoming more aggravated each year. Dr. Levinge's remarks are, unfortunately, only too true, and many asylums in this country have a similar experience, and we believe therein lies the explanation to a great extent of the alleged increase of lunacy. There is certainly much need for reform in this respect, as many cases are sent to asylums which ought to be sent to the workhouse or other suitable institution.

Seacliff.—The admission rate has been high—141—and 70 more patients are accommodated than the cubic space warrants. This makes itself felt in an unduly

high death-rate, and in epidemics of influenza and measles. Fifteen, or 30 per cent. of the deaths were due to tuberculosis. The inspector states the overcrowding must be provided for elsewhere.

Poriru.—The admissions numbered 101 discharges, recovered 24, and deaths 21. Dr. Hassell refers also to the committal of helpless and infirm patients to asylums. He suggests for consideration the erection of a separate building for recent and curable cases, and a home for nurses.

Literary Notes and Gossip.

DR. JOHN C. M'VAIL contributes an article on the Vaccination Acts to *Nature* of January 15th.

DR. PFITZNER, of Strasburg, well known by his valuable anthropological studies, is dead.

SIR M. FOSTER, M.P., F.R.S., contributes "A Prospectus of Science" to the January number of *The Quarterly Review*.

UNDER the editorship of Dr. J. Reynolds Green Messrs. Dent and Co. are about to commence the issue of a series of works having the general title "English Men of Science." They will portray the part played by Great Britain in the furtherance of scientific work.

HITHERTO the employment of ocean travel as a means to preserve or restore health has been directed too much by mere empirical considerations. The scientific method, however, is doing much to secure a more reliable basis for selection and guidance, and the recent article on "Oceanography," by Dr. Hugh R. Mill (*Encyclopaedia Britannica*, Vol. XXXI., 1902), will prove of much service in furthering precise information and is rich in valuable references.

MR. T. P. WHITTAKER, M.P., has reproduced his Lees and Raper Memorial Lecture for 1902, on "The Economic Aspect of the Drink Problem." Although dealing principally with the economic standpoint of the so-called Drink Question it contains much respecting its medical and scientific aspects and affords useful and carefully compiled information regarding the hygienic and sanitary considerations of the subject. The pamphlet is one which should prove of value as a concise and convenient source of reference.

THE coming into force of the new Licensing Act and the action now taken by magistrates and various public bodies in regard to habitual drunkards has focussed attention on the question of inebriety and stimulated serious study as well as encouraged practical effort in dealing with the victims. The London County Council has established a reformatory for female inebriates at Farmfield, and the report of the Inebriates Acts Committee, now published, not only indicates the nature of the excellent work there being carried out but contains much of suggestive interest for all engaged in dealing with this unfortunate and difficult class of patients.

MESSRS. BARR AND SONS, of Covent Garden, have sent us their new seed "Guide" for 1903, and as they offer to forward it post free, doubtless many of our readers who live in the suburbs of large towns, or in the country, will be glad to possess it at the coming seed time. The compilers, having extensive seed and plant farms in Surrey, can, and do offer practical hints on floriculture, fruit, and vegetable growing, and as each item is arranged alphabetically, with useful cultural hints, and a list of novelties and specialities for the new year, its contents will delight the heart of the amateur gardener and assist him in his choice of what to plant and when to plant.

Medical News.

Medical Libel Case.

AT the recently held Cardiganshire Assizes an action was tried in which Mr. G. R. E. Bonsall, medical officer of the Aberystwyth Union Workhouse, claimed damages for libel from the editor of the *Welsh Gazette*. It appeared that Mr. Bonsall had operated upon a woman, who subsequently died after an operation had been declared to be unnecessary, or, at any rate, undesirable, by the medical staff of the infirmary, the inference being that he had performed an unnecessary operation and had thereby accelerated the death of the patient. In the box Mr. Bonsall proved anything but a good witness, but in spite of his shortcomings in this respect the jury had no hesitation in returning a verdict in his favour with £10 damages. We will do newspapers the justice to say that it is very rarely that they wantonly throw such grave aspersions on medical men, who, even when mistaken, are never animated by any other object than the welfare of their patients.

Adjustable Stretcher Cover.

MAJOR R. CALDWELL, F.R.C.S., D.P.H., R.A.M.C., has devised an adjustable stretcher-cover having for its object to prevent the contamination of stretchers occupied by persons suffering from communicable diseases. It consists of a waterproof sheet of sufficient dimensions to cover all parts of the stretcher, including the pillow, which are likely to be brought into contact with the patient. It is furnished at each corner with tapes and buckles, by which it can be fastened to the stretcher handles and so secured against displacement. It can be readily adjusted, promptly removed, and easily cleansed or disinfected. It is manufactured by Messrs. Evans and Wormull, Stamford Street.

Fatal "Hot" Baths.

EVERY year a small but unfailling number of cases of deaths from scalding in baths are reported with remorseless certainty of recurrence. The facts of this class of tragedy are few and simple as they are absolutely preventable by the exercise of a modicum of common sense. The latest occurrence of this kind was investigated at an inquest held last week at Walthamstow, Essex, the deceased being an infant eighteen months old, who was brought to one of the female officers of the Salvation Army Home. With the aid of another officer the first mentioned procured a hot bath into which the child was plunged, on the assumption that it was "going into a fit." When in the bath the child suddenly began to "draw its breath," and on being taken out of the bath "the skin began to peel off the legs." The temperature of the bath was not tested before use. Amateur doctoring and nursing of this description is not altogether uncommon amongst philanthropists. We would suggest that in future the Salvation Army train their officers of Homes in ordinary ambulance work, and make it a standing rule to summon a medical man in cases of sudden sickness as well as to test the temperature of all baths both by thermometer and by the elbow of the attendant.

Zymotic Diseases in London.

There are at present only five patients suffering from smallpox under treatment in the hospitals of the Metropolitan Asylums Board. There are still 3,217 patients suffering from scarlet fever and diphtheria, but this figure shows a diminution on the number for the previous fortnight. The Gore Farm Convalescent Hospital is now practically closed.

An Unlicensed Private Lunatic Asylum.

A London magistrate last week fined a man named Albert William Gibbs, of Upper Holloway, for taking charge of an alleged lunatic in an unlicensed house. There were four inmates in all, two men and two women, but none of them were certified as mental cases. There was no attempt to show that the house was not cleanly and well appointed, or that it was not properly conducted. The defendant, however, had most clearly

exposed himself to the prosecution instituted by the Commissioners of Lunacy. Under the circumstances he may consider himself fortunate in escaping with the extremely light penalty of £5 and £5 5s. costs. Were this sort of thing permitted the thin end of the wedge might be inserted for the revival of the worst abuses of the liberty of the individual that look place in former times. In the interest of every one of his Majesty's subjects it is evidently necessary that absolute official supervision should be maintained over every individual kept under restraint for real or suspected lunacy. There is no doubt something to be said in favour of an elastic treatment of "borderland" cases, but that does not by any means imply that such patients may be withdrawn from the jurisdiction of the Commissioners. A thorough remoulding of the Lunacy Laws would be advantageous to most persons concerned. A flagrant abuse of lunacy law is to this day witnessed in Austria, where perfectly sane members of the Royal Family can be locked up for the rest of their lives and treated as insane if their presence be not acceptable at Court.

Royal College of Physicians of Edinburgh Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on the 28th ult., with the following results:—

First Examination—4 years' Course.—Henry Gordon Campbell passed the examination.

First Examination—5 years' Course.—Of 17 candidates entered the following nine passed the examination:—Scott Jackson Stenhouse, Nena Beatrice Ievers, George Isles Swanson, Hugh McIlroy, Thomas McClure, Alexander Paul Dias, Arthur Patrick O'Connell, Duncombe Steel-Perkins, and Thomas Campbell Dykes, and three passed in Physics, three in Elementary Biology, and four in Chemistry.

Second Examination—4 years' Course.—Of four candidates entered the following three passed the examination:—Angus Calder Mackay Macrae, James Henry Allan, and James Sydney Cooper.

Second Examination—5 years' Course.—Of twenty-two candidates entered the following nine passed the examination:—William Barclay, Capel Geary Dyer, Thomas Percy Cox, Robert Wearing, Samuel Ethelbert Mangénie, Narinda Singh Sodhi, William Watson, Sohrab Shapurji Antia, and Daniel Colin McNair, and two passed in Anatomy.

Third Examination—5 years' Course.—Of twenty-nine candidates entered the following fifteen passed the examination:—Solomon Newmark, Andrew Sergeant McNeil, George Arthur Charter, Charles Richard Whittaker, James Walsh, James Augustus Robertson, John Forbes Webster, L.D.S., Ernest Howard Edward Coghlan, Elizabeth Saunders Graham, Alfred Lionel Johnston, Malayampakhum Rajabahdur, Sidney Percival Joseph, John David Jones, Charles Stewart Hunter, and Rudolf Baranov, and three passed in Pathology.

Final Examination.—Of eighty-seven candidates entered the following thirty-seven passed the examination, and were admitted L.R.C.P. and S.E. and L.F.P. and S.G.:—Solomon Newmark, William Henry Burnhill, Walter Bartlett Chapman, John Lewis Maitland Govan, John O'Regan, Charles Mackie Begg, Lewis Beesly, John Wilson, William John Shorten, Dennis Woodley Purkis, William Ernest O'Hara, Helen Stephen Baird, George Harrison, Edward Graham Taylor, Patrick Francis Doorly, Robert Adair Lockhart, Alexander Wood, Oscar Wesley Haist, John Ellul, Thomas Taylor Smith, Donald Cameron, Daniel Sayre MacKay, John Arthur Denzil Rome, Madhava Lal Mallick, Mohamed Musharruf Ali, Shripat Govind Ranaday, Behram Burjorjee Bharncha, Jehangir Hormasji Contractor, Henry Joseph Patchett, Arthur Leslie Howard, H. Thomas, Sohrab Mancherji Hodiwalla, Frederick Herbert Maberly, Samuel Robert Scott, Frederick Russell Bremner, Ernest Farrant Cox, Neil Lipscomb, and Malayampakhum Rajabahdur, and fourteen passed in Medicine and Therapeutics, and one in Surgery.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial* and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

M. R. C. P. (London).—If you have any doubts as to the identity of the parasite, the best thing you can do will be to send it to a bacteriological laboratory for further identification. We are not prepared to undertake examinations of the kind, as there is no accommodation for parasites on our office premises.

THE SEA AS A SANATORIUM.

A sea voyage in ancient days was for many a consumptive the departure on the long journey which knows no return. The sea has, indeed, gone out of fashion as a resort for the phthisical. But much of the disappointment in the past was due rather to the unfortunate conditions of sea travel, and a lack of due selection of cases. A society has recently been formed, which is to devote its energies to a serious study of sea climate in its action on health and modifying influences in disease. Already sea sanatoria are being arranged for, and no doubt such will prove of much service, provided, however, the *mal de mer* does not introduce a disconcerting and discounting influence.

A. S. V. G. asks for information respecting an iron bed-table for invalids, he believes of American make, prospectus of which, with diagram, was distributed by post some months ago. The cost was about 25s. Perhaps some of our readers may be able to identify the appliance.

ANOTHER COMPLAINT.—If you will place us in possession of the facts under which the document came into the possession of the firm, we may be able to comply with your request.

M. R. C. V. S.—Certainly the company have the right to terminate a policy, "under conditions," whenever they please, the power to do so forming an integral part of such policies. Nor are they under any obligation to justify their action, which, moreover, cannot have any other object than to guard the company against an undesirable risk. Your contention that by cancelling a policy without just cause they may indirectly prevent your being accepted by any other company is plausible, but we suppose every company would be prepared to take each case on its merits, and, even though you might have ground for complaint, you would apparently have no remedy.

DR. C. WATERFORD.—Your letter received after the journal had gone to press. We will refer to the matter again in our next issue.

Meetings of the Societies, Lectures, &c

WEDNESDAY, FEBRUARY 4TH.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Annual Meeting. Specimens will be shown by Dr. Tate, Dr. Sikes, Dr. Elen, Dr. Groves, Dr. Inglis Parsons, Dr. H. R. Spencer, Dr. Blacker, Dr. Russell Andrews, and Mr. Handley. The President (Dr. P. Horrocks): Annual Address.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Cheries Street, W.C.).—4 p.m. Mr. A. H. Tubby: Clinique. (Surgical.) 5.15 p.m. Dr. J. Galloway: Erythematous Eruptions; their Relationship to General Diseases.

THURSDAY, FEBRUARY 5TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Papers:—Mr. N. Smith: Congenital Displacements of the Hips, including a description of Lorenz's method of Bloodless Reduction. Mr. S. Spokes: Immediate Regulation of Teeth.

RONTGEN SOCIETY (20, Hanover Square, W.).—8.30 p.m. Discussion on Some Points suggested by the Presidential Address of November, 1902 (opened by Mr. J. H. Gardiner).

FRIDAY, FEBRUARY 6TH.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.).—8.45 p.m. Paper:—Mr. C. J. Heath: Operative and other Treatment of Chronic Suppuration in the Middle Ear.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—5 p.m. Ordinary Meeting. Cases, Specimens, and Instruments will be shown by Mr. C. Symonds, Dr. Pegler, Mr. Lake, Mr. de Santi, Dr. B. Kelly, Mr. Stewart, Dr. Donelan, and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Cheries Street, W.C.).—4 p.m. Mr. P. R. W. de Santi: Clinique. (Ear.) 5.15 p.m. Dr. H. W. G. MacLeod: House Ventilation and Drainage.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (Society's Rooms, West London Hospital).—8.30 p.m. The Annual Discussion. Discussion on the Sequelæ of Typhoid Fever and their Treatment (opened by Dr. S. Taylor and continued by Dr. W. Hunter, Dr. A. Elliot, and others).

THURSDAY, FEBRUARY 12TH.

MEDICO-PSYCHOLOGICAL ASSOCIATION (County Asylum, Mickleover, Derby).—3 p.m. Members are invited by the courtesy of Dr. Legge to lunch at the Asylum at 1.30. Papers will afterwards be read by Drs. W. Lloyd Andriezen, Ernest W. White, and T. Outerson Wood.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square).—8 p.m. The President, Dr. Heywood Smith, will give his introductory address, and specimens will be shown by Dr. Macnaughton-Jones and others.

Appointments.

BALL, CHAS. ARTHUR, M.B., B.Ch., Assistant Surgeon to Sir P. Dun's Hospital, Dublin.

BYRNE, HERBERT U., M.B., B.Ch., Medical Officer of No. 4, South City Dispensary District, has been elected Visiting Physician to Cork Street Fever Hospital, Dublin.

CLEGG, J. GRAY, M.D., B.S., F.R.C.S., Honorary Surgeon to the Manchester Royal Eye Hospital.

ECCLES, W. MCADAM, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to St. Bartholomew's Hospital, London.

EMMANUEL, J. G., M.D., B.S., B.Sc. Lond., M.R.C.P. Lond., Second Physician for Out-patients at the Queen's Hospital, Birmingham.

HAY, JOHN, M.D. Vict., M.R.C.S., L.R.C.P. Lond., Honorary Pathologist to the David Lewis Northern Hospital, Liverpool.

HILL, CHARLES A., M.B. Cantab., D.P.H. Vict., Honorary Bacteriologist to the David Lewis Northern Hospital, Liverpool.

LEE, C. HOWARTH, M.B., Ch.B. Vict., Resident Medical Officer to St. Mary's Hospital, Manchester.

MONTGOMERY, HUGH MAYER, M.D., C.M. Edin., Honorary Physician to the West Cornwall Infirmary and Dispensary, Penzance.

NOALL, WILLIAM PAYNTER, M.B., B.S. Lond., M.R.C.S., L.R.C.P., House Surgeon to the Bradford Royal Infirmary.

PEARCE, THOMAS MANSEY, M.B., L.R.C.P. Lond., M.R.C.S., Honorary Medical Officer to the Ashburton and Buckfastleigh Cottage Hospital.

PRICE, THOMAS ARTHUR, M.B., Ch.B. Edin., Assistant Medical Superintendent at the Hospital for Insane, Toowoomba, Queensland.

SEATON, DOUGLAS, M.B., Ch.B. Vict., Honorary Surgeon to the Leeds Public Dispensary.

SCODER, D'ARCY, L.R.C.P. Lond., M.R.C.S., Honorary Medical Officer to the Ashburton and Buckfastleigh Cottage Hospital.

SYMONS, JOHN, M.R.C.S., L.S.A., J.P., Honorary Surgeon to the West Cornwall Infirmary and Dispensary, Penzance.

TEALE, M. A., M.R.C.S., L.R.C.P. Lond., Honorary Ophthalmic Surgeon to the Leeds Public Dispensary.

Vacancies.

Leeds General Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary to the Faculty.

North Riding Lunatic Asylum, Clifton, York.—Senior Assistant Medical Officer. Salary £200, with the usual emoluments. Application to the Medical Superintendent.

Bolton Infirmary and Dispensary.—Senior and Junior House Surgeons. Salary £130 and £100 per annum, with apartments, board, and attendance. Applications to W. W. Cannon, Esq., Hon. Secretary, 20, Mawdsley Street, Bolton.

Metropolitan Hospital.—Casualty Officer. Salary £150 per annum. Applications to Charles H. Byers, Secretary.

Birmingham Corporation Waterworks, Elan Valley, Radnorshire.—Resident Medical Officer. Salary £300 per annum, with board, lodging, and drugs provided. Applications to Mr. B. R. Body, Hon. Sec., Elan Valley Sick Club, near Rhayader, Radnorshire.

Bradford Royal Infirmary.—Dispensary Surgeon. Salary £100 per annum, with board and residence. Applications endorsed "Dispensary Surgeon," to William Maw, Secretary.

Children's Hospital, Sheffield.—House Surgeon. Salary £80 per annum, with board, lodging, and washing. Applications to Mr. Frederick Gill, Secretary, 14, Norfolk Row, Sheffield.

Medical Officer for Sugar Plantation in South-east Africa. Salary £200 to £250 per annum, with board and return passage. Three years' agreement. Applications to Mr. Stocker, 22, Craven Street, Strand, W.C.

County Asylum, Whittingham, Preston, Lancashire.—Assistant Medical Officer. Salary £150, with furnished apartments, board, washing, and attendance provided. Applications to the Medical Superintendent.

Royal National Hospital for Consumption and Diseases of the Chest, Ventnor.—Assistant Resident Medical Officer. Salary £100 per annum, with board and lodging in the Hospital. Applications to the Secretary, 34, Craven Street, Charing Cross.

Hampstead Hospital.—Resident Medical Officer. Salary £120 per annum, with rooms, coal, and gas. Applications to R. A. Othwaite, Honorary Secretary.

Birmingham Corporation Waterworks Elan Valley, Radnorshire.—Resident Surgeon. Salary £250 per annum, with board and lodging. Applications to Mr. E. Antony Lees, 44, Broad Street, Birmingham.

Births.

ORMEROD.—On Jan. 28th, at 87, Lansdowne Place, Hove, the wife of Ernest William Ormerod M.D., of a son.

TRACEY.—On Jan. 29th, at The Gables, Willand, Cullompton, Devon, to Dr. and Mrs. H. Eugene Tracey, a son.

Marriages.

RUSSELL—STERIKER.—On Jan. 28th, at St. Stephen's, Bow, George Herbert Russell, M.R.C.S., L.R.C.P., of Upton Park, second son of the Rev. John Russell, of Holy Trinity Barking Road, to Ethel Kate, eldest daughter of Robert Battam Steriker, of Bow.

Deaths.

CULPEPER.—On Jan. 28th, at Notting Hill, William Moe Culpeper, M.R.C.S., aged 83.

FFYFE.—On Jan. 29th, at Delhi, India, of pneumonia, Lawrence Bruce Fyffe, India Civil Service, youngest son of the late Surgeon-General Fyffe, of Clifton, Bristol, aged 25 years.

FORD.—On Jan. 23rd, at 5, St. Leonard's Road, Surbiton, Joseph Ford, M.R.C.S., L.S.A., late of Wedmore, Somerset, aged 74.

GILBERT.—On Jan. 28th, James Gilbert, Deputy Surgeon-General, late Bombay Army, aged 80.

JAY.—On Jan. 28th, at King's College Hospital, Frederick Waters Jay, only son of Frederick Fitzherbert Jay, M.D., of 8, Leicester Place, London, aged 33.

TURNER.—On Jan. 30th, at Sutton, Surrey, Jessie Caroline, widow of Surgeon-General John Turner, Bombay Medical Service, in her 63rd year.

WATKINS.—On Jan. 30th, at Kirby, Newton-le-Willows, suddenly, John Webb Watkins, M.D., aged 69.

The Medical Press and Circular.

Original Communications.

TOBACCO DEAFNESS.

THE PRESIDENTIAL ADDRESS DELIVERED BEFORE THE BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION, JANUARY 30TH, 1903.

By WYATT WINGRAVE, M.D.

Physician and Pathologist to the Central London Throat and Ear Hospital.

WE cannot fail to have observed the rapidly increasing consumption of a drug which is not only beyond all proportion to the increase of population, but promises to extend to a still greater degree, and, further, that its over-indulgence (especially by youths) is likely to be responsible for serious morbid changes, some of which are of immediate interest to us in one department of our work. I refer to tobacco. Its responsibility for certain morbid visual changes has been fully established, and observing the frequent occurrence of deafness in those suffering with tobacco amblyopia, it occurred to me that the association might be more than coincidental. This prompted a careful examination of such cases, with results which justify my submitting to you a preliminary communication on the subject.

The relationship between rhinology, otology, and ophthalmology has recently been before us, in the shape of Dr. Ziem's paper on "Diseases of the Eyes and Nose," and cases were shown by Mr. Mayo Collier and myself illustrating the occurrence of optic neuritis with middle ear disease, so that the field is not quite new to us, only embracing another aspect.

Most of the cases now referred to occurred in my hospital practice, some were seen in private, and others were referred to me by my colleagues. With regard to the ocular phenomena, the scotoma cases were verified by specialists in that department. It will suffice to briefly sketch the main features which were observed.

Deafness due to tobacco smoking may be conveniently classified in three groups, according to their etiology: (1) Mechanical or pneumatic; (2) irritative or catarrhal; (3) toxic or nerve deafness.

1. *Mechanical*.—This has its origin in the habit of smoking a tightly-packed pipe, cigar, or cigarette especially in those suffering with nasal obstruction. A violent minus or negative naso-pharyngeal pressure is exerted with each inspiration, not only upon the Eustachian tubes, but also upon the blood

and lymph vessels of the parts so leading to hyperæmia, upon whose symptoms and treatment we need not dwell.

2. *Irritative or Catarrhal*.—This form is very familiar in the early morning cough and expectoration of habitual smokers. It is caused by the chemical and mechanical irritation of the smoke on the mucous membrane extending along the Eustachian tube, and inducing also hypertrophic changes.

3. *Toxic or Nerve Deafness*.—This is due to the gradual accumulation of certain toxins of tobacco in the system. Whatever the actual poison may be, whether picrotoxin, nicotine, or any other, it is found as a rule in largest amount in the darkest, strongest, and cheapest tobaccos, e.g., cut plug, cut cavendish, shag, &c., also in cigars of the maduro strength, Oriental as well as Occidental. This poison is undoubtedly cumulative, since complete abstinence is essential to effecting any permanent improvement; mere reduction in the quantity consumed or of its strength generally proves unsatisfactory.

The effect of tobacco toxin upon the cardiovascular system is familiar to all of us. Also, its influence upon the gastro-intestinal tract which may be responsible for the production of further toxins. But its most striking effect is upon the nervous system, as exemplified in "tobacco amblyopia," a disease characterised by degeneration of certain bundles of the optic nerve, known as the papillo-macular fibres—scotoma—characterised prominently by the loss of appreciation of the visual red waves. Does the auditory nerve present a similar degeneration? Although at present we have no definite histological evidence, the fact that there was marked deficiency in the appreciation of low-tones in 50 per cent. of the cases recorded is presumptive evidence in favour of there being some selective degeneration at work in the auditory as in the optic nerves.

The effects of the toxins may possibly be terminal and central, but these are questions which also demand careful and extensive observations, both histological and clinical. The cases which I have examined are seventeen in number. They were those of typical "nerve deafness," for which no cause other than tobacco abuse could be found. To save time I give you a brief abstract of their chief features:—

Ages.—With regard to age, eight occurred between 24 and 40, and nine occurred between 48 and 64.

Tobacco.—They all smoked very strong tobacco or cigars and in large quantities.

Deafness.—They were all subjects of *symmetrical* nerve deafness; an appreciation of low tones was deficient in eight. Tinnitus and vertigo being generally well marked.

Vision.—There was marked impairment of colour sense—Red—in twelve, of which four had well-defined scotoma.

Treatment.—Treatment consisted of complete abstinence from tobacco in every form, with the administration of strychnia, quinine, or bromides.

Results.—Quinine, bromides, separately or combined, afforded no appreciable effect, but strychnia pushed to full doses proved more successful; three severe cases were completely cured in eight nine, and twelve months respectively; nine showed marked improvement; two improved only slightly; and two refused to continue treatment. That the improvement was in a great measure due to arrest of smoking was shown in several cases, which always relapsed on resuming the habit, although strychnia was persisted with. Improvement was again marked on abstaining from tobacco.

In conclusion, allow me to emphasise the following points:—

1. That they were all well-marked cases of nerve deafness (unattributable to other causes) occurring in heavy smokers.

2. That the loss of low-tones in 50 per cent. suggests an auditory equivalent for a recognised ocular lesion.

3. That there was definite scotoma in four cases and impaired sensation of vision in eight of them.

4. That the disease was symmetrical.

5. That 80 per cent. showed marked improvement on abstinence from tobacco, and, supplemented by drug treatment, three were cured. But the habit was so strong and the will so weak that the forecast was not always encouraging.

Although you will doubtless find in these notes many points of weakness and many deficiencies, still I trust I may have presented evidence sufficient to justify my selection of the subject, in view of a more thorough clinical analysis in the near future, and also of eliciting the views of those whose wider experience of scotoma may enable them to speak with greater confidence.

CASES OF TOBACCO NERVE DEAFNESS.

1. Ch. S., æt. 24. Warehouseman. Complete deafness and noises R. Duration, nine months. Smokes 3 ozs. shag weekly. Rinné +, Air C. — 12. Low T—. Difficulty in reds. Treatment, quinine. Result, marked improvement in four months.

2. T. M., æt. 50. Horsekeeper. Deafness B.E. Tin. R. Duration, nine years. Smokes 1 oz. shag daily. R. meatus — 40, mastoid — 30, Rinné — L. meatus — 30, mastoid — 20. Low tones — Colours: Green = Blue, red = difference in brilliancy. R being dull. L bright. Treatment, pot. brom. Would not give up tobacco, but smoked lighter variety. Improved slightly.

3. J. B., æt. 26. Clerk. Complete deafness and tin. Duration, six months. Smokes 3 ozs. weekly. Meatus and mastoid both —. Rinné +. Low tones lost. Colour sense, reds dull. Treatment by strychnia. Result, improvement in two months.

4. E. P., æt. 54. Carpenter. Deafness left. (C.C.M.E. and N.D.) Duration, ten years. Smokes heavily; lately only $\frac{1}{2}$ oz. shag daily. Meatus both —. Mastoid both +. Rinné +.

Low tones —. Under treatment for scotoma, which is better since arrest of smoking. Lost sight of.

5. C. H., æt. 54. Labourer. Complete deafness in R. ear, with tin. and giddiness. Duration, six months. Smoking, $\frac{1}{2}$ oz. Cavendish (black) daily. Meatus, both —. Mastoid, both —. Rinné, both +. Lones tones —. Vision nyctalopic. Slight scotoma. Colours Red = brown. Treatment, quinine and strychnia. Would not change habit, and no change in symptoms.

6. A. R., æt. 40. Ostler. Complete deafness R.E. Duration, six years, on and off. For months lately had been a great smoker, and very deaf at times, but improved on diminishing tobacco. Smokes $\frac{1}{2}$ oz. shag daily. Meatus, R. — 6; Mastoid — 10. Rinné, +. L. — 4, Mastoid —, Rinné, +. Colour, reds almost gone. Well-defined scotoma. Treatment, strychnia. Reported great improvement.

7. F. K., æt. 34. Blacksmith. Complete deafness in R.E. Duration, four years. Smokes $\frac{3}{4}$ ozs. navy cut weekly. R. Meatus, — 12, mastoid — 6, Rinné + L. Meatus — 15, mastoid — 5, Rinné + Vision, reds = chocolate; faint scotoma. Treatment, strychnia. Result, lost sight of.

8. J. T., æt. 60. Painter. Complete deafness. Duration, ten years on and off. Smokes $\frac{1}{2}$ oz. shag daily; lately less. R. Meatus, — 8, Mastoid — 4, Rinné +. L. Meatus — 12, mastoid — 5, Rinné + Low tones. — Vision, colour, reds dirty. Under treatment for scotoma. Treatment, strychnia. Four months later reported better.

9. M. W., æt. 64. Farmer. Complete deafness and noises. Duration, four years. Smoked 1 oz. shag daily; always been a great smoker. R. Meatus — 4, mastoid — 6, Rinné +. L. — 7, mastoid — 8, Rinné +. Colour sense, no note. Low tones weak. Treatment at first, bromide, then strychnia under the latter gave up tobacco, and in seven months reported great improvement.

10. E. G., æt. 56. Park keeper. Complete deafness. Duration, four years. Great smoker, 2 ozs. dark Virginia daily. R. Meatus — 6, mastoid — 7, Rinné +. L. Meatus — 2, mastoid — 2, Rinné +. Colour good. Low tones—. Treatment, strychnia, no tobacco at all. Result, twelve months cured; reduced smoking to almost nil.

11. S. H., æt. 34. Complete deafness, twenty years, with noises, and E.T. Smokes $\frac{1}{2}$ oz. weekly. R. Meatus — 4, mastoid — 6, Rinné, +. L. Meatus — 10, mastoid — 4, Rinné +. Treatment, removed tonsils and bromides; no result in two months, stopped smoke, and ordered strychnia, marked improvement in two months. Colour sense good.

12. J. S., æt. 22. Deafness and noises B.E. Duration, thirteen months; onset gradual. Slight smoker. R. Meatus, — 2, mastoid + 4, Rinné + L. Meatus — 8, mastoid — 17, Rinné +. Vision history of weak eyesight R. Treatment, liq. strychnia, no tobacco; marked improvement in one month; cured in eight months.

13. M. T., æt. 53. Farmer. Complete deafness and noises and giddiness. Duration, two years, on and off. Smoker moderate. R. Meatus — 8, mastoid — 10, Rinné +. L. Meatus — 20, mastoid — 20, Rinné +. Treatment, stopped smoking and strychnia, and hearing improved but not tin.

14. M. M., æt. 30 Navy. Increasing deaf-

ness. Duration, three years. Smokes 3 ozs. black navy cut per week; always a great smoker. R. Meatus — 4, mastoid —, Rinné +. L. Meatus — 9, mastoid +, Rinné +. Colour sense difficulty with red regarded it magenta. Treatment, Fellow's syrup and no tobacco. Result, marked improvement in four months.

15. Male, æt. 48. Waiter. Complained of deafness and noises. Duration, ten years. Smokes six cigars daily, always a smoker. R. Meatus — 6, mastoid +, Rinné +. L. Meatus — 6, mastoid —, Rinné +. Low tones—. Vision weak, defective; reds defective. Treatment quin. hydroburn. Result, marked improvement in three months.

16. Male, æt. 49. Fitter. Complained of deafness and noises on and off for twelve months. Smokes freely, but an abstainer from alcohol. R. Meatus — 8, mastoid — 4, Rinné +. L. Meatus — 6, mastoid — 5, Rinné +. Vision good but had been weak. Treatment, strychnia and Eustachian catheter for sub. A.C.M.E. Result, marked improvement in each symptom.

17. J. J., æt. 40. Barman. Deafness for four years. Smoked 3 ozs. navy cut daily. R. Meatus — 10, mastoid — 4, Rinné +. L. Meatus — 8, mastoid — 6, Rinné +. Vision weak. Treatment, strychnia. Result unascertained, January 24th, 1903.

THE
USE OF CHLOROFORM
AS AN
ANÆSTHETIC FOR DENTAL
OPERATIONS. (a)

By T. PERCY C. KIRKPATRICK, M.D.,
Anæsthetist to the Dental Hospital, Ireland.

THE question as to whether or not chloroform should be used as an anæsthetic agent in dental surgery has, I think, been satisfactorily decided, in this country at all events, and it is not the practice of the Anæsthetists to use it for that purpose in the Dental Hospital of Ireland. Chloroform, is, however, still used to a considerable extent for this purpose in other places, and it seemed to be suitable that we should consider its physiological action and dangers so that you might be in a position to judge of the soundness of our practice. This is of more importance since in general surgery chloroform is the anæsthetic almost always selected in the case of prolonged operations on the mouth and nasal passages, and so, reasoning by analogy, one might be led to think that in dentistry it should be selected in place of ether.

Chloroform, or the terchloride of methyl CHCl_3 was discovered in the year 1831, and was first used for anæsthetic purposes on the human subject in the year 1848 by Sir James Y. Simpson, of Edinburgh. It is a colourless mobile liquid with pleasant but penetrating smell and sweet fiery taste. Its sp. gr. at a temperature of 17°C is 1.491, and its boiling point is 60.16°C . or 140.2°F ., its vapour density compared with air is 4.199. It is found that chloroform is less liable to decomposition when it has added to it traces of ethyl alcohol, and consequently the "British Pharmacopœia" directs that a sufficient quantity of absolute alcohol should be added to it to produce a liquid with a sp. gr. of not less than 1.490 and not more than 1.495. It is most important that the drug when used for anæsthetic purposes should be pure and the "British Pharmacopœia" lays down many tests to which it should conform. The best way to ensure getting a good article is to buy it from a good maker, and the best test of its reliability is to inhale some of the vapour,

and if as Professor Ramsay says "it goes into the lungs easily and there is no feeling of coughing or oppression of any kind," it is probably quite pure. "Chloroform containing a small quantity of carbonyl chloride has a harsh feeling and irritates the bronchial tubes and altogether produces a different sensation." Chloroform readily decomposes when exposed to white light, so should always be kept in coloured bottles and in a dark place.

There are two chief methods of administering chloroform which are known respectively as the open method, and the method by measured dosage. The description is not a very happy one, as in both methods free access of air and admixture of it with the chloroform is aimed at. In the former method the drug is dropped or poured on a Skinner's mask or folded napkin or towel and the patient breathes in the vapour of the drug freely mixed with air. Sometimes an open cone is used and the patient draws in the air through a sponge on which the chloroform has been poured. The principle which underlies the use of all these different forms of apparatus is, however, the same namely, presenting a diluted vapour to the patient and judging of the dose necessary by the effects produced on the patient. The second method aims at giving to the patient a definite quantity of chloroform vapour with each respiration which will be just sufficient to produce and maintain a satisfactory anaesthesia. The rationale of this method is based on the following considerations.

When air containing chloroform vapour is brought to the alveoli of the lungs, a certain proportion of the chloroform is absorbed into the blood and the quantity so absorbed will vary with the tension or quantity of chloroform in this air. The quantity of chloroform which the air can hold in solution varies with the temperature and pressure of the atmosphere, being governed by the same law which determines the quantity of watery vapour which the air can retain in solution. Thus at the ordinary atmospheric pressure a hundred cubic inches of air will take up the following quantities of chloroform at different temperatures:—

| | |
|------------------------|--|
| Temperature Farenheit. | Cubic inches of CHCl_3 vapour |
| 45° | 8 |
| 50° | 9 |
| 55° | 11 |
| 60° | 14 |
| 65° | 19 |
| 70° | 24 |

Recognition of this fact is of importance as you see that when giving chloroform in the ordinary way increase of the temperature of the atmosphere some 15°F may double the amount of chloroform available for absorption. Now chloroform will enter the blood till the tension of the chloroform in the residual air in the lungs and in the blood is equal, and when once that equilibrium is established none of the drug can enter or leave the blood by the pulmonary mucous membrane as long as that equilibrium is maintained.

From this Snow arrived at the general law:—"As the proportion of the vapour in the air breathed is to the proportion that the air or space occupied by it, would contain if saturated at the temperature of the blood, so is the proportion of vapour absorbed into the blood to the proportion the blood would dissolve." Now Snow, by very elaborate experiments and calculation arrived at the quantity of chloroform which it was necessary should be dissolved in the blood to produce the various stages of anaesthesia, and by his application of this law has laid down how much chloroform should be mixed with the air breathed in order to arrive at this result. Snow made the following division of the stages of chloroform-anaesthesia. Snow says "In the first degree I include all the effects of chloroform that exist while the patient retains a perfect consciousness of where he is and what is occurring around him. In the second degree of narcotism there is no longer correct consciousness. The mental functions are impaired, but not necessarily suspended. When a patient inhales chloroform quietly for a medical or surgical purpose, he usually appears as if asleep in this degree; but if his eyelid be raised, he will move his eyes in a

(a) Paper read before the Dental Students Debating Society of Ireland, January 14th 1903.

voluntary manner. There are occasionally voluntary movements of the limbs, and although the patient is generally silent, he may nevertheless laugh, talk, or sing. In the third degree of narcotism there are no longer any voluntary motions. The eyes for instance are not directed towards any object, and although the limbs may move they are not directed to any purpose. The pupils are generally inclined upwards in this degree, and are at the same time somewhat contracted. It is in this degree of narcotism that rigidity and spasms of the muscles occur in certain cases. The rigidity and spasm are greatest and most constant in labourers and persons accustomed to athletic exercises and they are usually absent in persons who have been long confined to the room or are much reduced in strength from any cause, I have seen the spasms take an epileptiform character in a few cases; but by gently continuing the chloroform they have always been subdued. In the fourth degree of narcotism the breathing is stertorous, the pupils dilated, and the muscles completely relaxed. It is very seldom necessary to carry the effects of chloroform as far as this stage. If the dose of chloroform is gradually increased after these effects are produced, the breathing entirely ceases, but the heart continues to pulsate very distinctly, till its action becomes arrested by the absence of respiration as in asphyxia. This interval, including the embarrassment and cessation of breathing, I call the fifth degree of narcotism."

Snow calculated that to induce the third degree or the condition in which surgical operations are usually commenced would require that about 18 minims should be absorbed by an average adult or about 1.42 of the saturation of the blood. For the fourth degree about 28 minims or 1.28 of the saturation, while to arrest the function of respiration would require about 36 minims or 1.14 of the saturation of the blood. Taking the tidal air of the ordinary adult respiration as 25 cubic inches we can see from the following table how much chloroform should be volatilised with each respiration to produce the desired percentage of vapour in the air. 1.20 of a minim of CHCl_3 gives 0.23 % vapour in air

| 1-10 | " | " | 0.46 | " " |
|------|---|---|------|-----|
| 1-5 | " | " | 0.92 | " " |
| 2-5 | " | " | 1.84 | " " |
| 3-5 | " | " | 2.76 | " " |
| 4-5 | " | " | 3.68 | " " |
| 5-5 | " | " | 4.6 | " " |

breathed.

Since air when saturated at a temperature of 100° F. will take up 43.3 cubic inches of chloroform vapour we see that

| | |
|---------------------------|----------------------|
| 0.23 % of vapour is about | 1.200 of saturation. |
| 0.46 | 1 100 |
| 0.92 | 1.50 |
| 1.84 | 1.25 |
| 2.76 | 1.17 |
| 3.68 | 1.13 |
| 4.6 | 1.8 |

These fractions are only approximate, but they are close enough for our purpose, and from them by the application of Snow's law we can estimate the saturation of the blood which will be produced by breathing each strength of vapour. Thus the constant administration of 1.5 of a minim of chloroform with each respiration should, in an adult, produce the third degree of anaesthesia in about five minutes. In actual practice we find that somewhat more is necessary, as of course, a considerable quantity is lost with each expiration. Now although by such experiments and calculations Snow was able to estimate the exact amount of chloroform that should be administered to produce the desired effects, yet in practice he found that about 4 per cent. of vapour in the air breathed was the most suitable proportion for causing insensibility for surgical operations. On this point he makes the following remark. "The great point to be observed in causing insensibility by any narcotic vapour, is to present to the patient such a mixture of vapour and air as will produce its effect gradually, and enable the medical man to stop at the right moment. Insensibility is not caused so much by giving a dose as by performing a process. Nature

supplies but one mixture of diluted oxygen, from which each creature draws as much as it requires, and so, in causing narcotism by inhalation, if a proper mixture of air and vapour is supplied, each patient will gradually inhale the requisite quantity of the latter to cause insensibility according to his size and strength. It is indeed desirable to vary the proportion of vapour and air, but rather according to the purpose one has in view, whether medicinal, obstetric, or surgical, than on account of the age or strength of the patient; for the respiratory process bears such a relation to the latter circumstances, as to cause each person to draw his own proper dose from a similar atmosphere in a suitable time."

The action of all the regulating inhalers is based on this consideration of presenting vapours of suitable and known strength, from which the patient can absorb the necessary quantity of the drug. As a type of these we may take the Junker as modified by Krohne and Sesemann of London. In this the face-piece consists of an open cone with a feather placed in such a position over the opening that it moves up and down with each respiration. Into this face-piece a definite quantity of chloroform vapour is delivered at the beginning of each inspiration. The bellows attached to the chloroform bottle consists of three rubber balls of different sizes. The smallest of these has a cubic capacity of 10 cc., the middle one a capacity of 30 cc., and the largest of 60 cc. At a temperature of 60° F. a complete compression of the small ball, yields the vapour of 1.6 of a minim of chloroform to the face piece, of the middle ball 3.6 of a minim, and of the large one 6.6 of a minim. In other words the small ball gives a percentage of chloroform in the tidal air of 0.76, the middle ball of 2.3, and the large one of 4.6. By means then, of this inhaler it is possible to carry out easily the principle of Snow and to be sure that at no time can the patient get too strong a vapour. As the apparatus is used the temperature of the chloroform falls slightly so that less of the drug would be vapourised, and at ordinary temperatures it would probably not be possible to get from the large ball a vapour of more than 4 per cent.

I have gone thus minutely into this question to show you the necessity of guarding the dosage in chloroform administration, but I do not for a moment wish you to think that you can render such administration perfectly safe simply by the use of measured doses, no matter how carefully they are measured. There are many other factors which have to be taken into consideration as well, but if one is careful not at any time to administer more than 4 % of chloroform in the air breathed, and at the same time see that the respiration is maintained perfectly free and unobstructed, the danger from the use of chloroform will be reduced to a minimum.

We have seen from Snow's experiments that if a person gradually gets an overdose of chloroform the respiration first ceases and then the heart, but it is also perfectly well established that sudden death from cardiac syncope may take place under chloroform, and that too quite early in the administration.

I do not intend to go deeply into the question of the physiology of the action of chloroform, but merely to tell you what are the most recent views which appear to have both clinical and experimental justification as to its action on the nervous and vascular systems. Waller, in an elaborate series of experiments which he described before the British Medical Association at the Montreal Meeting in August, 1897, showed that when an isolated nerve is exposed to the action of various anaesthetic vapours it rapidly loses its excitability and becomes as he calls it "immobilised." If the nerve has not been subjected too long to the vapour, or to too strong a vapour, it rapidly recovers its excitability when removed to fresh air. It was further found that the power of recovery varied with different anaesthetics, and that in the case of chloroform the nerve was much more apt to be killed or rendered permanently immobile than was the case with ether. In fact from these experiments Waller concluded that chloroform was seven

times as strong a nerve poison as ether. This conclusion is to a great extent borne out by clinical experience, for we find that generally speaking we use about the same number of drachms of chloroform as we do ounces of ether in a similar case. The exact physiological action of chloroform on the central nervous system is not known, nor, indeed, is it known by what action on the nerve centres any anæsthetic produces its anæsthetic effect. The action of chloroform on the circulation and the vascular system generally has been the subject of much dispute, and even yet it cannot be said that physiologists have come to an agreement on the matter. The chief question in dispute was: Does chloroform exert any depressing action on the heart? The Hyderabad Commission, which met chiefly with the idea of solving this question, replied to it in the negative, stating that chloroform had no action whatever on the heart itself. This statement has not, however, been accepted by physiologists, and it has been shown that in many points the methods of the Commission were faulty, and so the result obtained cannot be relied on. It may be taken as established that chloroform acts as a depressant on the musculature of the whole vascular system, producing a lowered blood-pressure and a tendency to paralytic dilatation of the heart. At the same time it has been shown that the action of chloroform tends to reduce that power which the vascular system normally possesses of counteracting the action of gravity on the circulation produced by changes in the position of the patient. For example, the blood-pressure in a normal cat remains fairly constant, no matter what position the animal is made to assume, but if the animal be anæsthetised by chloroform alterations in position produce very marked alterations in blood-pressure. Quite recently, Dr. Embly has brought forward some very remarkable investigations which he carried on with dogs with the view of explaining the early and sudden death which so often occurs during the administration of chloroform. The conclusions which he has arrived at may be given shortly as follows:—Heart muscle is very sensitive to the poisonous effects of chloroform. Chloroform raises the excitability of the vagus mechanism, particularly in the early part of the administration. This increase in the excitability is due to the action of chloroform on the centres. The administration of a weak chloroform vapour after a period of mild excitation depresses vagus excitability, and a stronger percentage in the air inhaled may cause dangerous and persistent inhibitions.

Vagus inhibition is in dogs the great factor in the causation of sudden death under chloroform. Failure of respiration in inhalation experiments is mainly due to fall in blood-pressure, and restoration of respiration is dependent on restoration of blood-pressure. The chances of dangerous vagus inhibition in chloroform administration are greatly increased by imperfect respiration, and as respiration fails when the blood-pressure falls greatly, from cardiac inhibition or other causes, we have the material for the formation of a vicious circle. For example, supposing, as happens in some cases, that from the inhalation of too strong chloroform vapour cardiac inhibition occurs, this occasions a dangerous fall of blood-pressure; the cessation of respiration and the asphyxia consequent thereon themselves increase the inhibition. These conclusions, based on very elaborate and carefully carried out experiments, are of the utmost importance from a practical point of view, and it is not too much to say that everyone who undertakes the responsibility of administering chloroform should be familiar with them and their applications to practice.

Let us now turn our attention to the question of the use of this drug in dental surgery, and see if from the materials at our disposal we can arrive at any definite conclusions as to whether we should or should not use it. The advantages of the drug are many and obvious, and if among them we could include the element of safety it would undoubtedly be largely used in place of ether. It is, however, just the absence of this element of safety that determines our practice. Clinical experience has shown that a large number of deaths

occur during the use of this drug for dental and other surgical operations of a like nature, and our knowledge of its action suggests to us that it is the conditions of the operation which render the drug unsuitable.

Chloroform has the advantage of being, as a rule, easy to take, portable as regards the apparatus necessary, rapid in its action, and at the same time affording a typically good class of anæsthesia which can be prolonged indefinitely without detriment to the operator or operation. If, then, we add to these advantages the fact that it is probably the only anæsthetic many medical men have any experience in the use of we cannot wonder that it is sometimes used.

The large majority of dental operations can be completed in three minutes or less, they are too long for a single administration of nitrous oxide, or even nitrous oxide and oxygen, but it is felt that there is not the necessity to induce the same degree of anæsthesia which is usually adopted in the case of surgical operations, which may take half an hour or more. This idea leads to the tendency to hasten the induction by pressing the drug, and often to starting the operation before full surgical anæsthesia is established. Both these practices are distinctly dangerous in the case of chloroform, and liable to be attended with serious results. If a strong chloroform vapour is presented to a patient, it is very liable to cause sudden death, as we have seen, by over-stimulation of the already excited vagus centre and at the same time it is likely to cause holding of the breath, which, in itself, is likely to add to the danger which already exists. So, too, any sharp reflex stimulation of peripheral nerves during the stage of imperfect anæsthesia may induce this vagal inhibition of the heart and cause sudden death. From this we learn that the anæsthesia should with chloroform be induced slowly and with very dilute vapours, and that no surgical operation should be undertaken till full anæsthesia has been established. Anything which tends to interfere with the freedom of respiration is attended with danger during chloroform anæsthesia, especially since it has the double disadvantage of further obstructing the already depressed heart and the liability of causing an overdose of the drug by preventing elimination of it from the lungs.

When we remember the effect that I have already told you chloroform has on the heart there is no difficulty in appreciating the danger of placing a patient who is under its influence in the upright position. This should never be done under any circumstances, on account of the danger of syncope, and this fact alone renders chloroform unsuitable as an anæsthetic in dental operations. When patients are placed lying on their backs, as would be necessary for such operations, there is a great danger of blood being sucked into the air passages, and either causing immediate asphyxia or starting later an aspiration-pneumonia. In the cases where this drug is used for ordinary surgical operations on the mouth special precautions have to be taken to prevent the occurrence of these troubles. Thus, in some cases the head is hung over the end of the table as is done in cleft palate operations, or the pharynx is plugged and the chloroform is administered through a tracheotomy tube. There is one class of operation in surgery in which the conditions very closely approximate to those of a dental operation; I refer to the operation for the removal of post-nasal adenoids and tonsils. In both a short anæsthesia is required, but though short, still a longer time is often wanted than can be got by a single administration of nitrous oxide, and in both cases a rapid recovery is desired to enable the patient to expectorate the blood. Like dental operations, too, the operation in itself is devoid of immediate danger and should never cause death, yet we find many deaths recorded from it. In this connection, let me read you an extract from a paper by Mr. Henry Chaldecott, Anæsthetist to the Metropolitan Throat, Nose and Ear Hospital, and reported in the *Lancet* of September 13th last. "The operation *per se* entails no immediate risk to life, and one can hardly conceive the possibility of a patient dying on the table or in the chair if operated upon without an anæsthetic. It follows,

D

then, that any fatalities which have occurred have been caused by the anæsthetic employed, and so far as I have been able to ascertain the anæsthetic has in every recorded case been chloroform or some mixture containing chloroform. I have collected a list of more than fifty recorded cases of death under chloroform given for this operation, including children and adults; cases in which the chloroform was given by specialists in anæsthetics, and cases in which it was administered by general practitioners and house-surgeons; cases of death at all stages of the procedure, before the commencement of the operation, during the operation, and after its completion. Now this list lays no claim to being exhaustive, and could probably be largely increased. What, then, is the obvious deduction? That here we have an operation which ought to be, and is in itself, absolutely free from immediate danger, perverted by the use of chloroform into one of the most immediately deadly of all in the long list of surgical operations. Is there any one surgical operation—major or minor—which can claim such a record of deaths upon the table? I doubt it. Since 1897 more than thirty recorded deaths have taken place from chloroform during adenoid operations only." A very similar paragraph might have been written about dental operations, and I very much regret that I have not complete figures at my disposal to bring before you. I have myself gathered from some of the medical papers of the last few years the records of four deaths under chloroform, administered for a dental operation, and probably the list could be greatly augmented. In the *Journal* of the British Dental Association for the year 1895, Hewett, in a paper on this subject, makes the following statement: "I have taken a period of fifteen years—i.e., from 1880-1894 inclusive, and have exerted every means in my power to obtain particulars of all fatalities which have occurred during this period in Great Britain in connection with the use of anæsthetics for dental operations." The following table gives the result of these inquiries:—

| Anæsthetic used. | England and Wales (excluding London). | | |
|--|--|---------|---------|
| | Scotland. | London. | London. |
| Chloroform | 12 | 15 | 0 |
| Chloroform and morphine | 1 | 0 | 0 |
| Chloroform (3 parts) and ether (1 part) mixed | 0 | 1 | 0 |
| Methylene | 0 | 2 | 0 |
| Ether | 0 | 1 | 0 |
| Nitrous oxide | 1 | 2 | 2 |
| Total | 14 | 21 | 2 |

"We find that out of this total of thirty-seven fatal cases no less than twenty-seven occurred in connection with the use of chloroform; and if we include the chloroform-and morphine case, the chloroform-and-ether case, and the two cases which arose in connection with the use of the so-called methylene (which experience has shown to consist largely of chloroform), we may say that out of the thirty-seven cases no less than thirty-one took place in association with the use of either chloroform or some combination containing chloroform." In regard to the ether and nitrous oxide fatalities Hewett tells us that the former occurred from mechanical asphyxia, principally due to a cancerous growth in the mouth, and in a patient in such a state of health as to render the administration of any anæsthetic at the time particularly hazardous. One of the nitrous oxide fatalities resulted from the entrance of a tooth into the larynx. Hewett further says: "Nothing, I think, could show more clearly the lethal influence of chloroform as a dental anæsthetic. In London, where it is not used, the ratio of deaths to the population is extremely small; in England and Wales (excluding London) where chloroform is used, but not to the extent which obtains in Scotland, the ratio is considerably higher; and in Scotland itself, where chloroform is the routine anæsthetic—at all events for all major dental operations—the ratio is very much higher."

I have tried to tell you something of the nature of chloroform, of its modes of administration and its

physiological action; I have given you some figures indicating its dangerous nature when employed in dental and similar operations in order that you may be able to appreciate the grounds of our practice in the Dental Hospital, Ireland, where the use of chloroform never obtained a footing, and I trust when in practice yourselves, unless you have some good reason to the contrary, you will avoid its use also.

OCULAR HEADACHES. (a)

By SYDNEY STEPHENSON, C.M.,

Ophthalmic Surgeon to the Evelina Hospital, &c.

(Concluded from page 103.)

It might possibly be assumed from some of the above cases that from the first moment a patient begins to wear glasses his complaints cease forthwith. Such, however, is by no means the case. If the error of refraction is almost fully corrected, many patients have to go through a period of more or less discomfort before they reach a time when the glasses are really comfortable and relieve a headache from which they may happen to suffer. Many highly organised people have considerable difficulty in becoming used to glasses, and some, alas! will not persevere long enough to obtain any relief. If the glasses are correct—not always an easy thing to make a patient believe—the only remedy is time. The uncomfortable feelings gradually become less and less marked, until, in the course of two or three weeks, they are no longer experienced. One annoying effect of correcting astigmatism in adults by cylindrical glasses is the production of "binocular metamorphopsia." This manifests itself by an apparent distortion in the shape of familiar objects—as, for example, a picture frame, which may appear to be wider at one end than the other, although it is in reality oblong. The same sort of distortion is seen when going up and down stairs, and under other conditions that need not be more particularly specified. The change, which, as the name implies, is only visible when both eyes are open, has been accounted for in various ways. But the simplest explanation would be that there is a natural conflict and contradiction going on in the patient's mind between the impressions of a life-time and those resulting from the correction of an astigmatic and ametropic eye. Binocular metamorphopsia, as a rule, is complained of by observant people, and, above all, by artists. It can be overcome only by the constant and persevering use of the correcting glasses.

The following case will illustrate the foregoing remarks upon the subject of binocular metamorphopsia:

In September, 1893, a lady æt. 50, consulted me on account of failing sight. Each crystalline lens showed signs of incipient cataract. R.V. $\frac{1}{8}$ —1.0 D $\frac{1}{8}$. L.V. $\frac{2}{3}$ —2.5 D. Cyl. axis 60° $\frac{1}{8}$. Making due allowance for the presbyopia that was present, the following glasses were prescribed for near work:

R.E. +1.5 D Sph. L.E. $\frac{+2.0}{-2.5 60^\circ}$. With these

glasses the patient, whilst in my room, could read the smallest print. A day or two after she had got her glasses I received the following very emphatic letter from the patient:—"I have received my glasses, but am sorry to say they are quite a failure. I can see across a room very much better without than with them, and even when reading they make the page quite aslant. My husband and two of my children have put them on and they make everything appear crooked to them as they do to me. I have naturally a sharp eye for detecting if anything is out of the straight, and am usually sent for when pictures are rearranged in the house to see if they are straight, so that I cannot in the least understand why the glasses produce this distortion. Possibly they would distort objects to you as they do to me if you looked through them."

In conclusion, a few words may be added about *megrim*, an affection that, in my experience, is often

(a) Paper read on January 9th, 1903, before the Wimbledon and District Medical Society.

connected closely with ocular defects. This is no new observation, inasmuch as the connection was recognised by Piorry nearly seventy years ago, and has been commented upon by many writers, including Airy, Liveing, Ranney, Hewetson, Lauder Brunton, and Stevens, since that time. Indeed, in 1882, Dr. Savage (a) of Jackson, U.S.A., announced that he had discovered the "real cause" of sick-headache to be hypermetropia and astigmatism, and that its successful treatment consequently consisted in the use of proper glasses. In 1885, H. Bendelack Hewetson (b) laid stress upon the fact that correction of the eyes by cylindrical glasses relieved not only the headache, but also the intermediate dyspepsia, insomnia, and irritability of temper liable to occur in some patients between the attacks of megrim. A year later (1886) Dr. Ambrose L. Ranney (c) stated that "the symptoms of sick-headache are reflex in character to a large extent, and are due primarily in almost every case to some optical defect."

Nowadays few people would probably care to go so far in their statements as Drs. Savage and Ranney, although at the same time it must be admitted that many cases of megrim are closely connected with eye-strain.

Let me quote the following case where the sequence of cause and effect appeared to be singularly free from fallacy: a very intelligent medical friend had suffered slightly from megrim since he was seven years of age, but as he got older, and especially as he was reading for his professional examinations, the bouts had become severer and more frequent. He was affected, in fact, with classical "blind headache." The attacks began with a coloured and scintillating obscuration of central vision, and as this passed away, as it generally did in five to ten minutes, intense unilateral headache supervened. The attacks were always associated with nausea. They were brought on by (a) indigestion, and (b) straining the eyes, as with the microscope. There was a family predisposition to megrim; the patient's mother and sister suffered severely from the affection, and two of his children were also affected. The headache, as a rule, did not last for longer than an hour, but on one occasion it persisted for four days without intermission. General remedies did little, if any, good. At last, at the age of about 39 years, the slight hypermetropic astigmatism (0.5 D) was corrected with spectacles for constant wear. The result was almost magical. The headaches became fewer in number and milder in character, and this has continued until the present time, some fifteen years after the glasses were prescribed. It may be added that severe headaches can still be induced by attempting to use the eyes without glasses.

In the next case the relief afforded by weak glasses was very prompt and striking:—Grace C—, æt. 22, consulted me in November, 1902. She was a fine, robust-looking country girl, but had always been subject to headaches, which had become worse during the last two years. The pain, which was ushered in by ocular spectra, affected the frontal region, and generally lasted a whole day. It was followed by vomiting. She generally had two or three such headaches during the week. The eyes were stated to ache and to get red after close work. The headaches were definitely induced by reading or working. General medical and dietetic treatment had proved useless. Upon examination no defect of the external ocular muscles could be found; there was 1 D of hypermetropia in the right eye and 0.75 D in the left eye. Spectacles correcting this small amount of long-sight were ordered for constant wear. After six weeks' use of the glasses, Miss C— reported that there had been no return of the headache, and that there was no aching, &c., of the eyes.

Megrim, contrary to what is sometimes thought, is far from rare in childhood. Nevertheless, it is perhaps

uncommon to elicit a clear account from young patients of the classical symptoms, so that cases must often be overlooked. I have met with fairly typical attacks in children as young as six years. The following case, although occurring in an older child, may be quoted because one or two unusual symptoms were present:—George D—, æt. 10, had suffered from three attacks of megrim, the first in the autumn of 1900. The attacks commence with an alteration in speech and a numbness of the right arm, and are followed by persistent vomiting. There is a strong family history of typical hemicrania, preceded by hemianopsia, in the mother and in several of her people. The patient, upon examination under atropine, was found to be affected with an extremely low grade of hypermetropic astigmatism, and the weakest cylinder of the trial case (+ 0.25 D), with its axis horizontal, was ordered for constant use. In the result, the megrim disappeared completely, and had not returned when the patient was seen a year afterwards.

I shall occupy no more of your time by quoting further instances of the relief or cure of megrim by the use of spectacles, although there would be no difficulty in doing so, but I shall simply say that, in my opinion, the eyes in every case of megrim should be examined as a matter of routine practice. I have good grounds for believing that in such cases relief can often be obtained by correcting the strain and confusion that arises in people of neuropathic disposition from even a small error of refraction or fixation. At all events, the experiment is worth trial in every case of so-called "sick-headache."

Now to turn to a second possible cause of ocular headaches, namely, the balance of the external muscles of the eyeball. Normally, those muscles should be so adjusted by means of their nervous supply as to cause objects, near or distant, to be fixed exactly and simultaneously by the two eyes. In other words, the visual axis of the eyes should meet at any object towards which they are directed, owing to a correct innervation of the external muscles of the eyes. If this state of muscular equilibrium is disturbed, a squint, manifest or latent, will be the result. The manifest or obvious squint we may leave on one side, but the latent squint is of interest from our present point of view. Provided the sight of the two eyes is approximately equal, the instinctive desire for binocular vision is usually so strong that although one eye tends to deviate inwards or outwards, yet it is restrained from doing so by involuntary innervation, which, though unfelt, may give rise to a condition of muscular asthenopia.

A special nomenclature has been designed to indicate the various kinds of muscular anomaly. Thus, the condition of the eyes in a state of normal muscular balance is called *Orthophoria*, while all departures are grouped under the name *Heterophoria*. If there be a latent convergence of the eyeball, we speak of *Esophoria*, and an excess of divergence is known as *Exophoria*. The last-named condition has been known to oculists for years as "insufficiency of the internal recti muscles," and is commonly associated with the higher degrees of myopia. *Esophoria*, on the other hand, is often combined with hypermetropia. Should the visual axis of one eye tend to deviate upwards the condition is known as *Hyperphoria*—"right" or "left," according to the eye affected. Combinations of these muscular defects may occur.

When these muscular defects give rise to symptoms of discomfort (which is by no means always the case) they may be relieved in several ways, of which the chief are correction of associated ametropia, the use of prisms, exercise of the defective muscle or muscles, tonics, out-door exercise, and operations upon the muscles.

These muscular anomalies have been studied chiefly in America, where, rightly or wrongly, heterophoria is credited with producing not only eye-strain and headache, but even such different disorders as neuralgia, insomnia, disturbances of nutrition, neurasthenia, chorea, epilepsy, and some forms of insanity.

(a) Savage.—*Medical and Surgical Reporter*, Philadelphia, July 29th, 1882.

(b) Hewetson.—*Medical Times and Gazette*, March 21st, 1885.

(c) Ranney.—*New York Medical Journal*, February 27th, 1886.

With regard to disorders of nutrition and derangements of nervous function, they are not seldom relieved by correction of ametropia, apart altogether from the question of muscular balance or imbalance. For example, Dr. Weir Mitchell quotes the case of a feeble, nervous, anæmic woman, æt. 30, with trifling hypermetropic astigmatism, who lost all pains, headache, and fatigue by wearing her glasses constantly. "The change in her appearance," wrote Dr. Mitchell, "was remarkable, and was, I think, solely due to relief of the strain with which she used her eyes." An interesting case of my own may be quoted in this connection. It is as under:—Theodora G—, æt. 12, the daughter of a medical man, came to me on September 22nd, 1900, complaining that use of the eyes for more than a few minutes brought on pain in the eyes and in the frontal region. It appeared from the history that a brief attendance at school always induced symptoms of an impending nervous breakdown. The child lost flesh, got white, and her health became extremely poor. This led the parents to send the girl when ten years of age to Tasmania. On the voyage the patient put on flesh and seemed healthy in every way, but when sent to school soon after reaching Tasmania, all her former symptoms reappeared. A change to the mountains of Wesley Dale in the colony was tried, but without success. Finally, after staying for a year in Tasmania, she returned to England. Another ophthalmic surgeon, who had examined the child just before I did so, stated that the eyes were not at fault, or rather that so little was the matter with them that there was no need to interfere. Upon examination, I found the sight almost but not quite normal ($\frac{1}{2}$ partly). There was some exophoria, corrected by a prism of $1\frac{1}{2}$ D base in. Under atropine, slight compound hypermetropic astigmatism was found, and the following glasses ordered for all purposes:

R.E. $+0.25$ Sph. $+0.50$ Cyl. 80° . L.E. $+0.5$ Sph. $+0.5$ Cyl. 70° . The symptoms were relieved at once by the glasses, the child became brighter and better in all ways, and she was able to attend school just like any ordinary girl. In November, 1902, there was a slight recurrence of the headaches, coinciding with a change to a school where greater demands were made upon the eyes. Symptoms, however, soon subsided after a slight change had been made in the axis of the cylinders, and a brief trip undertaken to Switzerland.

The view that heterophoria may cause chorea and epilepsy and insanity has met with little favour in this country, where much less importance appears to be attached to disorders of fixation than in the United States. The condition is common enough in England, but practically only in association with errors of refraction. Here the general opinion seems to be that its effects can be minimised by correction of the co-existing ametropia, without special attention to the muscular anomaly itself. Hence, in England we hear little of the "graduated tenotomies," so dear to the hearts of many trans-Atlantic surgeons.

Speaking for myself, I have met with a few, but very few, cases of vertical deviation, where headaches were promptly relieved by suitable prisms. It will suffice to quote a single case of this description:—Amelia P—, æt. 26, complained of vertical headaches, which had commenced when about fifteen years of age. They had become much worse since an attack of scarlet fever six or seven months before I saw the young lady. They were brought on by use of the eyes, and were most marked during her menstrual periods. There was no error of refraction, but a right hyperphoria of 1 D existed. This was fully corrected by a prism of $\frac{1}{2}$ D before each eye, and the result was both prompt and satisfactory.

(2) *The general health and constitution of the patient.*—It is clear that an error of refraction or of muscular balance is more likely to cause headache if the patient is in poor health, as from influenza, or debilitated, as from lactation or a recent confinement. It is far from uncommon for discomfort to make its appearance for the first time under such circumstances, even although

the ocular defect may have existed from childhood or even have been congenital. The explanation is simple. The general condition has involved the ciliary muscle and so has rendered it unable to compensate hypermetropia or hypermetropic astigmatism. The converse is to some extent also true. The effects of eye-strain can often be relieved, for a time at all events, by the giving of tonics, the use of physostigmine to the eyes, and the leading of an out-door and active life.

Then, complaints of headache are apt to be particularly pronounced in that numerous class of people who have inherited or acquired an unstable nervous system—the "neuropathic" disposition, as George T. Stevens (a) calls it.

Occupation, also, is not without influence. An ocular defect that would pass unperceived in an agricultural labourer would be apt to cause distress in a highly-cultured person.

In short, we should expect asthenopia to be marked under the following conditions and circumstances;—(1) In patients who are recovering from some general illness; (2) in those of neuropathic disposition; (3) in those of sedentary habits, who use the eyes for long together; (4) in persons of good social standing and of more than ordinary education; and (5) in children and those who belong to the female sex.

MAX SÄNGER:

A Biographical Record.

By H. MACNAUGHTON-JONES.

THROUGH the recent death (January 12th, 1903) of Professor Säger, gynecology has lost one of its greatest ornaments, and Germany one of her most distinguished teachers. His unaffected simplicity, his genial and courteous manner, the pains he ever took with all who visited his clinic, gained for him a universal regard. When the sudden blow came which initiated his long and weary illness, tragically commencing in the midst of an operation, all the scientific world of medicine in Germany and Austria-Hungary felt it as a personal grief. Säger was a stupendous worker; indeed, no one can estimate the full output of that laborious life who has not glanced through the list of his published works and writings. These covered every subject in the branch which he practised, having written as many as some hundred and thirty communications, from the time that he commenced his career as a doctor in 1875 until he was compelled to relinquish work.

Säger was born in Bayreuth on May 14th, 1853. He studied medicine in Würzburg and Leipzig, obtaining his degree of doctor in the latter university in January, 1875. He was assistant from 1876 to 1878 at the Polytechnic of Medicine and the Institute for Pathological Anatomy under Professor Wagner, becoming Privat Dozent from 1878 to 1881. He was a wide seeker after knowledge, and studied at various clinics outside his own country. He worked under Crédé's personal management, becoming operator in the gynecological clinic, continuing in this position until 1887, when Zweifel took over the duties. Meantime, he inaugurated a private Gynecological Poly-clinic, which in 1891 he had rebuilt and reorganised. Here now his old pupils and co-workers, Professors Krönig and Menge, have their clinic. He thus obtained material for his scientific work in Leipzig. In 1890 he became Professor Extraordinary. In 1896 he was appointed Medical Adviser to the Royal Family of Saxony, when the First Class Knight's Cross of the St. Olsforden's Order was bestowed on him. He was corresponding and honorary member of many foreign societies. In 1899 he became Ordinarius and President of the Gynecological Clinic in Prague. Here he worked hard at the completion of the Frauen Klinik in the new Emperor Franz Joseph Pavilion, a building which was completed and set in full working order in December, 1899. Only those who, like the writer, have seen the completeness of that clinic can appreciate the perfection of the arrangements therein, where every modern

(a) Stevens.—"Functional Nervous Diseases," New York, 1887.

idea has been availed of to make it complete both from a clinical and teaching point of view. Professor Kleinhaus, who assisted Sanger in the clinic, has succeeded him, and I am especially indebted to my genial friend, Dr. Schenk, Professor Sanger's first assistant, for most of the particulars of this sketch.

From 1889 Sanger was co-editor of the "Archives of Gynaecology," and in 1894 he founded, with the veteran Auguste Martin (now of Greifswald), a monthly journal of obstetrics and gynaecology which should have a cosmopolitan character, and which, independently of the original articles appearing in it, should indicate the progress of gynaecology all over the world. He also collaborated with Professor v. Herff, of Halle, in publishing an "Encyclopedia of Obstetrics and Gynaecology." The majority of Sanger's writings are to be found in the *Archives fur Gynakologie* and the *Centralblatt* during the twenty years of his active literary career, though he read several important papers at the International Medical and Gynaecological Congresses, as those of Breslau, Bonn, Rome, Brussels, Vienna, and Geneva.

As far back as 1881 he wrote his paper on the technique of amputation of the supravaginal myomata of the uterus (*Central. f. Gyn.*, 1881), and his name was associated with the earlier steps for vaginal total extirpation of the carcinomatous uterus. He was an advocate for the moist rather than the dry aseptic methods of intra-abdominal hemostasis. During the eighties he wrote several papers on Cæsarean section, advocating this step in preference to conservative measures or the Porro operation, making several suggestions as to the better method of performing the operation and its technique. He warmly advocated the views of Noeggerath on the latency and permanent consequences of gonorrhoea, and the later sequelae which follow that disease after long periods of quiescence. Most valuable were the additions that he made to our knowledge of the surgery of the urinary organs through his contributions on trans-peritoneal nephrectomy ("Surgical Text-Book," Thiersch), "The Surgery of the Female Urinary Passages" (*Central. f. Gyn.*, 1892), and on the "Abdominal Uretero-cysto Anastomosis in Uretero-genital Fistulas." Needless to say, he was a warm advocate for asepsis, both in midwifery practice and gynaecology. In 1889, Sanger distinguished and differentiated, under the title of "Deciduoma malignum," certain malignant tumours composed of deciduous or placental elements having special characteristics apart from other uterine neoplasms ("Zwei aussergewohnliche Falle von Abortus," "Ueber Sarcoma uteri deciduo-cellulare"), and again in 1893 he drew attention to these same decidual tumours, and his was practically the first systematic description of the tumour, not but that Maier, in 1875, had written on tumours of the body of the uterus composed of decidual tissue. It may be said that deciduoma malignum is now all but universally acknowledged to be a typical affection *sui generis*. His name was associated with the earlier efforts at abdominal uterine suspension, and as early as 1886 and 1888 he suspended a freely movable uterus by unilateral peritoneal fixation, his name being associated with that of Olshausen in the development of the operation known now by the name of the latter. Not in this direction only did he do much original work, but also in the domain of all plastic operations on the vulva, vagina, and cervix. He quickly recognised the originality of Lawson Tait's principle of operation, and advocated it. We also owe to Sanger, in conjunction with Auguste Martin, Brieske, and a few others, our earlier knowledge of the affection of the vulva known as *kraurosis vulvæ*, Sanger pointing out the secondary atrophic condition following upon the inflammatory stages of the affection.

This is but a brief survey of the more important work of the distinguished Prague professor. Many classical and philosophic papers also issued from his pen, such as that on the "Universal Causes of Female Diseases," which subject he took for his opening academical address, delivered in Leipzig in 1892, and that on "Mechanical Disintegration, Infection, and Propy-

laxis," delivered in Prague in 1900. The last time he visited England was in 1898, when he took part in the meeting in Edinburgh, and he was present at the address of his old friend, Professor Martin, given to the Gynaecological Society in London.

Professor Sanger has left three children to inherit the lustre of his name. Frau Sanger has many friends in England, medical and other, who feel for her that deep sympathy which her sad loss has evoked.

Clinical Records.

BEDFORD COUNTY HOSPITAL.

A Case of Renal Sarcoma.—Nephrectomy.

By S. J. Ross, M.B., Ch.B.,

Surgeon to Out-Patients, Bedford County Hospital.

(From Notes taken by Dr. Newton, House Surgeon.)

THE patient was a boy, et. 4.

Previous history.—The only illnesses from which the patient had suffered were infantile cholera in his first year and again in his second year.

Present illness.—During the winter of 1900, his parents noticed that his eyes and hands were occasionally puffy; his urine was dark "like the beer out of the bottom of a barrel." Early in September, 1901, he complained of pain in his stomach. He was admitted into the Bedford County Hospital, under the care of Dr. Coombs, on October 12th, 1901.

Condition on admission.—Patient extremely pale. Abdomen distended. Mercurial ointment was applied to the abdomen. The bowels were kept regular by aperients. The stools were clay-coloured. *Urine* very small in quantity, revealed on examination albumin and hemoglobin.

Upon carefully examining the abdomen there was discovered a tense swelling three inches in diameter. Fluctuation was present. This swelling was evidently continuous with a large, round, elastic smooth mass, occupying the right side of the abdomen, reaching inwards to the middle line, above to the right costal margin, and downwards to two inches below the umbilicus. The mass above was easily palpable, and lower down, and only on deep pressure. Lower and outer borders rounded. Absolute dulness over the upper part as far as one inch above the umbilical level, below that tympanitic from overlying colon. The swelling somewhat tender on manipulation. The lower margin of the liver palpable, about an inch below the costal margin.

Diagnosis.—The case was regarded as one of hydro-nephrosis.

Mr. Nash, the senior surgeon, having been operating upon a septic case, asked me to cut down upon the kidney. This I did. Upon opening the capsule, blood gushed out. The examining finger broke down soft sarcomatous tissue. The nature of the case being evident, the incision was increased towards the umbilicus and the kidney removed. Adhesions were found to the colon and under surface of the liver.

Subsequent history.—Temperature fell from 101° to subnormal on the evening following operation. It rose again three days later to 100·8°. An aperient reduced it to normal, the temperature remaining normal till the date of discharge, December 4th, five weeks after operation. The average quantity of urine passed after operation till December 4th was 21 ozs. collected, besides some urine passed involuntarily. The urine still contains a trace of albumin.

Remarks.—Upon an error in diagnosis the surgical steps taken were founded. We had to deal with a renal swelling, which increased rapidly in size, and was accompanied by diminished secretion of albuminous urine.

The physical signs which pointed to the renal origin of the tumour were:—

1. The presence of a swelling in the right loin, the borders of which were rounded.
2. Dulness in the right flank continuous with liver dulness, the lower border of the latter organ being definable.
3. Slight descent of the tumour on respiration.
4. Colonic tympany elicited over the tumour.

What might this swelling be?

Cystic disease of the kidneys.—In this condition both kidneys are usually affected. The surface of the swelling is irregular. The late symptoms of this condition are (1) diminished secretion of urine; (2) uræmia. In the case under consideration, the left kidney was apparently normal. The surface of the swelling was smooth. The rapid increase in the size of the swelling was also an unusual feature.

Hydronephrosis.—The kidneys are developed from the metanephros, the ureter from the metanephric duct. Sometimes at the junction of the ureter with the infundibulum of the pelvis of the kidney, there is an obstruction which leads to hydronephrosis. The history of these cases is painless enlargement of the affected organ, with signs of a renal tumour. When only one kidney is affected the secretion of urine may remain normal, from compensatory hypertrophy of its fellow; on the other hand, there may be a diminution of urine from reflex causes. There may be rapid increase in the size of the swelling due either to (1) one cyst bursting into another, or (2) an incomplete obstruction becoming complete.

Renal abscess or tuberculous kidney.—There is usually a history of pain in the lumbar region, and pus is present in the urine.

Sarcoma of the kidney. is usually congenital, but may first make its appearance during the first few years of life. Siebert collected fifty cases and found that forty occurred during the first five years of life, ten occurred in infants under twelve months. In one case a sarcoma of the kidney was discovered in a foetus born dead. In these cases hæmaturia was present at some time or other in nineteen cases.

Hæmaturia is a rare symptom. As one would expect, the growth is really perinephritic, originating in the cells lining the renal capsule. The renal tissue disappears by pressure atrophy. The diminished secretion of urine is partly of reflex origin. Usually a painless enlargement, it may become painful if local peritonitis with adhesion to surrounding structures occur, e.g., as in the above case, where adhesions took place to the liver and colon. The growth is rapid. Usually both kidneys are affected. In structure it is either a round or spindle-celled growth. In the case under consideration it proved to be a round-celled growth. To one or two further points I should like to refer.

1. *Hæmoglobinuria.*—With the profound anæmia present in this patient there must have been a rapid breaking up of red blood corpuscles, with the result of a large quantity of hæmoglobin being freed. The anæmia was probably of uræmic origin.

The rise in the temperature previous to operation was probably due to hæmorrhage occurring in the growth and by the absorption of fibrin ferment.

The clay-coloured stools were the result of pressure upon the duodenum by the tumour. The constipation was probably partly of uræmic origin and partly due to adhesion of the growth to the colon.

Four months ago the patient was alive.

In these cases is operation justifiable? This case seems to warrant an affirmative answer. At any rate, his life was prolonged, and comparative comfort followed the operation. In a similar case I should most certainly advise operation. The irritation of a growing tumour in one kidney acts as a reflex inhibitor to the secretion of the comparatively sound kidney, and in all probability uræmia is more often attributable to this cause than to lack of secreting renal tissue.

I have to thank Drs. Goldsmith and Le Fanu for their able assistance at the operation.

Mrs. Mary Ann Snow, Maida Vale, who died on October 6th, and whose estate has been valued at £87,541, has bequeathed to the cancer research fund of the Middlesex Hospital £700, to the cancer wards of the Middlesex Hospital £500, to the research fund of the cancer hospital at Brompton £500, to the London Mission, for their Home for the Dying, £500, to the Kingsdown Orphanage £500, and to the Society for the Prevention of Cruelty to Children £500.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, FEBRUARY 4TH, 1903.

PETER HORROCKS, ESQ., M.D., F.R.C.P., President, in the Chair.

A CASE OF PROFUSE MENINGEAL HÆMORRHAGE IN A FŒTUS DURING LABOUR.

DR. SIKES showed a foetus which was born after a normal labour lasting under twelve hours, the second stage taking three hours. Nothing unusual was noticed except that there was some delay in the dilatation of the soft parts. The external pelvic measurements of the mother were normal, but the internal conjugate was contracted to a slight extent. The child's head was, if anything, rather below the normal size. The mother was a primipara. The child developed general convulsions soon after birth and died. Post mortem, under the scalp and beneath the meninges, there was copious hæmorrhage, covering both hemispheres and pretty evenly diffused. No hæmorrhage into the ventricles nor into the substance of the brain. The bones, of the foetal skull were very imperfectly ossified and resembled parchment. He recalled that several cases of the kind had been reported by Dr. Spencer ten years ago.

DR. HERBERT R. SPENCER thought with the author that the hæmorrhage was due to the softness of the bones, and he recalled the fact that in his paper on the subject he had pointed out that it was not only general softness of the cranial bones, but more especially that of the anterior cornua of the parietal bones which lay over some veins. If these were obstructed by pressure they would give rise to hæmorrhage from the sinuses. The softness of the bones in some cases was extraordinarily pronounced. He had noted in his paper that in every child which had died after delivery by the forceps there was extensive meningeal hæmorrhage.

THE PRESIDENT mentioned that the difficulty in establishing breathing in newly-born infants which was sometimes experienced, even when the heart was beating vigorously, was often due to hæmorrhage into the medulla oblongata.

DR. SIKES, in reply, said he had examined the medulla but had failed to detect any trace of hæmorrhage. He had examined ten or a dozen infants who had died after forceps delivery, and they had never found any hæmorrhage into the medulla, though possibly if sections had been made this would have been detected.

FŒTAL ASCITES AS AN OBSTACLE TO DELIVERY.

DR. EDEN showed a foetus whose abdomen had been the seat of enormous ascites. The history was as follows: The mother, a single primipara, had been in labour for twenty-four hours when, as no progress was made, she was given a teaspoonful of liquid extract of ergot in brandy, and this was repeated several times during the following day. After being forty-eight hours in labour a leg was found to have prolapsed and an attempt was made to deliver, although the cervix was not properly dilated. The foot came away, and on pulling on the leg that came away also, the foetus being macerated. The same thing happened on the other side and an attempt was then made to grasp the trunk with the craniotomy forceps, but unsuccessfully. He was then asked to see the patient, but experienced great difficulty in making out the position. Ultimately he located the sacrum, and then found that the part presenting was the much distended abdomen of the foetus. He opened it with scissors when much clear liquid escaped and delivery was then effected. The foetus was much macerated and appeared to have died two or three weeks before. The abdominal cavity was much dilated and the thoracic organs were displaced upwards. The bladder was distended, this

being due to an imperforate urethra. There was no hydronephrosis or distension of the ureters. He observed that the pathology of these cases was obscure, though syphilis had been incriminated in some cases and peritonitis in others. In this specimen there was no trace of peritonitis, and though syphilis could, of course, not be excluded there was no definite history pointing thereto. The liver and portal circulation showed no change. A case had been recorded by Herman in which the ascites was due to a new growth pressing upon the portal vein, but this was the only case on record due to this cause.

Dr. SPENCER observed that the specimen belonged to a rare class of which he had seen several instances, two or three as marked, as in this instance, and three others with a smaller amount of fluid in the abdomen. In the "large" cases he had been unable to make out any cause, although in one instance there was hydronephrosis with greatly distended ureters. In the second category there was a strong presumption of syphilis, and there was marked peritonitis with large flakes of lymph. He thought that there could be no doubt that syphilis was a potent factor in the production of this abnormality.

Dr. MALINS said the case was interesting from several points of view. He had met with such a case some years ago, after Sir James Simpson had pointed out that the condition was not infrequent. The cause in that case was tuberculous peritonitis leading to hydroperitoneum. There was the same difficulty in recognising the source of the fluid as there was no evidence of syphilis or of obstruction to the portal circulation.

The PRESIDENT said one point of interest was that the urethra was obliterated. He recalled a case in which labour was obstructed consequent upon the obliteration of the urethra in a female child. In this case the vertex was down so that the difficulty in effecting delivery was very great. The practitioner in charge called in a colleague who tore the arms away and the patient died suddenly just as he (the speaker) arrived at the door, death being due to rupture of the uterus. The abdomen of the fœtus was greatly dilated by the enormously distended bladder. The Fallopian tubes were of great size and the uterus was also very large. This ought to teach that when the child was dead it was idle to attempt to get it away in its entirety, the interests of the mother claiming their undivided attention. Such a child should be lessened in bulk as much as possible to expedite delivery.

Dr. SIKES asked whether the placenta presented anything abnormal.

Dr. EDEN, in reply, said he had discovered nothing wrong with the placenta.

EXTRAORDINARILY RAPID DEVELOPMENT OF A NEW GROWTH.

Dr. INGLIS PARSONS related the case (with specimen) of a woman who came with a large rounded tumour in the abdomen reaching up to the ribs. She had menstruated three weeks before admission. It was diagnosed to be a multilocular ovarian tumour, and it was removed. On examination it was reported to be a cystic adenoma. He had tapped it, but the fluid was too viscid to escape through the trocar. There were one or two slight adhesions to the omentum. She did perfectly well until the thirteenth day, when she complained of pain, and a swelling was made out behind the uterus, which rapidly increased in size. Feeling certain that there was no pus, the temperature not being raised, he delayed further intervention for some days, but had ultimately to intervene *in extremis*. She died the next day, when the ureters were found blocked with new growth, and there were numerous metastases in the organs. It proved to be a round-celled sarcoma. He pointed out that the tumour had first been noticed a year previously, so that it had not grown rapidly. She was well nourished and free from emaciation, and the adhesions were but slight. The interesting feature was the extraordinarily rapid evolution after operation.

A NEW FORCEPS AND NEEDLE-HOLDER.

Dr. H. G. SPENCER showed a novel and ingenious instrument which served as forceps and needle carrier. When armed it pulled the needle through so that suturing was made very easy. It was known as the Kurz forceps or needle-holder.

The PRESIDENT then delivered the Annual Address.

The PRESIDENT pointed out that the laws of the society were altered twelve months ago so as to enable ladies who were legally qualified to practise medicine to join the society. During the year no less than ten ladies had availed themselves of this privilege and no doubt their number would speedily increase. Also a new law had been passed whereby authors of papers could publish their work in other journals than the "Transactions" of the Society. This had been found to work satisfactorily. The new standing Pathological Committee had done excellent work. No less than fifty-nine specimens had been shown during the year, and these were above the average in interest and importance. A brief account of the nine papers which had been read was given, with the chief opinions expressed during the discussions upon them. Obituary notices of deceased Fellows were given—namely, John Griffith Lock, of Tenby; John James Tweed, of London; Thomas Robert Lombe, of Torquay, who had been a Fellow ever since the foundation of the Society in 1859; James Neal, of Birmingham; and Henry Oldham, Consulting Obstetric Physician to Guy's Hospital. Oldham was born in 1815, and died at the age of eighty-seven, in November, 1902. He received his medical education at Guy's Hospital and was appointed Obstetric Physician to that hospital at the same time as Dr. Lever in 1849. He was one of the best lecturers Guy's ever had, and his lectures are still remembered by a large number of practitioners. His style was dramatic. Interesting details of his life obtained from his colleague, Sir Samuel Wilks, from his friend and pupil, Dr. Constantine Holman, and from his son, Colonel Oldham, were given. He was one of the first Vice-Presidents of the Society; its third President, its second Treasurer, and one of its first three Trustees. He held this latter post until his death, that is, upwards of forty years. Dr. Champneys had been elected to fill his place in this respect. Thanks were given for able assistance during the President's two years of office to Dr. Herbert Spencer, who was Senior Honorary Secretary during the first year; and to Dr. Amand Routh, who had fulfilled the duties of that office during the second and last year.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD ON FEBRUARY 4TH,

SIR T. R. FRASER, President, in the Chair.

Dr. GEORGE GIBSON showed a

CASE OF ADHESIVE MEDIASTINAL PERICARDITIS in a lad who had suffered for six months from dyspnoea and œdema of the legs. On admission to hospital there was marked cyanosis, anasarca, ascites, and albuminuria. The fingers showed no clubbing, the liver was greatly enlarged, and the spleen was palpable beyond the costal margin. The physical examination of the heart was entirely negative, but the pulse was a very characteristic example of *pulsus paradoxus*. Examination of the blood showed from 7,500,000 to 8,000,000 red corpuscles with from 93 to 105 per cent. of hæmoglobin. A sign, which was necessary before the diagnosis of adhesive pericarditis could be regarded as absolutely established—viz., inspiratory collapse of the veins of the neck—was not present in this case. No other explanation of the signs than that given, however, seemed feasible.

Dr. JOHN THOMSON showed a child evincing a peculiar form of giant growth. The patient was a girl, æt. 5 years and 11 months, and was about 23 lbs. heavier, and 4 ins. taller than the average at that age, resembling in size a child of nine or ten. The hands and feet were small and delicate in relation to the size of the head and trunk, thus differing from

acromegaly. The ring fingers were short, and the little fingers incurved. The overgrowth involved the soft tissues as well as the bones, the features being large and the trunk covered by a thick layer of fat. The voice was gruff and harsh. The eyes were normal and no limitation of the visual fields had been made out. There was a slight amount of general debility, and the child was mentally below par. There was no paralysis, sensibility was normal, slight ankle-clonus and an extensor response of the great toe were present. The increased growth apparently had only become noticeable a few years before.

Dr. MELVILLE DUNLOP showed two

CASES OF SYPHILITIC ARTHRITIS IN CHILDREN, a brother and sister. In the former there was symmetrical synovitis of the ankles, wrists, elbows, and, to a less extent, of the shins and clavicular articulations. There was also a considerable amount of swelling of the left side of the face, with oedema of the soft parts and enlargement of the neighbouring glands. This was apparently due to periostitis of the superior and inferior maxillæ, and considerably interfered with the function of the temporo-maxillary joint. There was neither pain, stiffness, creaking, nor actual deformity of the joints, which seemed against rheumatoid arthritis, while the diffuse nature of the affection had seemed against syphilis. The diagnosis of the specific nature of the condition was, however, confirmed by finding thickening along both ulnar bones, and by seeing the sister of the patient (shown) who suffered from typical syphilitic synovitis of both ankles and knees. As a rule, syphilis affected only the knee-joints; it was excessively uncommon to get so diffused a synovitis as in the case of the boy exhibited.

Mr. COTTERILL showed (1) gangrene of gall-bladder in a case of cholelithiasis; (2) sarcoma of skin; (3) parenchymatous goitre; (4) sarcoma of testicle, with metastases in the brain, heart, lungs, liver, and intestine; (5) symmetrical exostoses of tibia, occurring in above sarcomatous patient; (6) round-celled sarcoma of undescended testicle closely simulating cartilaginous tumour of testis.

Dr. ALEXANDER BRUCE read a paper on
DOUBLE PARALYSIS OF THE LATERAL CONJUGATE
DEVIATION OF THE EYES.

The patient was an unmarried woman, æt. 27, healthy till her fifteenth year, when she suffered severely from anæmia, and very often fainted. There was a family history of tubercle. The illness, on account of which she sought advice, had followed a fall from a ladder, which had rendered her unconscious for about twenty minutes. After recovering from this she became liable to attacks of giddiness, which were especially frequent in the street and caused her to fall towards the right side. She then became aware of a feeling of stiffness on looking to the left side and on the left side of the mouth, particularly on speaking. Previous to coming under Dr. Bruce's observation she had been examined by an oculist, who had discovered a crossed diplopia due to paresis of the left internal rectus; on examination by Dr. Bruce there was almost complete left facial paralysis, and the left palpebral aperture was wider than the right. On looking to the right side the right eye moved almost to the outer canthus, the latter part of the movement being carried out in a series of nystagmoid jerks; the left eye did not move so far to the right, but lagged behind slightly. On attempting to look towards the left the eyes remained parallel, but did not pass beyond the middle line. The convergence of the eyes was perfect. The diagnosis was a lesion of the left sixth nucleus, which innervates the external rectus of the same side, and the internal rectus of the opposite side, through the posterior longitudinal fasciculus, uniting it with the opposite third nerve nucleus. A lesion in this position would easily catch the fibres of the left seventh nerve curving round the nucleus of the sixth, and also the fibres of the opposite posterior longitudinal fasciculus converging fibres to the left internal rectus. It would thus account for the paralysis of the left external and right internal recti and the left facial, and the paresis

of the left internal rectus. In addition to these symptoms there was some disturbance of the muscular sense, as shown by difficulty in touching the points of the fingers together. As time went on the vertigo increased, vomiting set in, and the patient complained of left-sided headache. Conjugate deviation to the right became difficult and finally impossible, and ultimately there was complete paralysis of lateral conjugate movements both to right and left. The patient died with symptoms of tuberculous meningitis, and on post-mortem examination a small tubercular nodule was found in the floor of the fourth ventricle invading the sixth nuclei on both sides. The case was of interest on account of the extreme definiteness and circumscribed character of the lesion, and because it had enabled a demonstration to be made of the course of the fibres from the sixth nuclei to the opposite internal recti. It was found that degenerated fibres could be traced in the course of the posterior longitudinal fasciculus from the sixth to the opposite third nuclei, but no further, thus proving that the sixth nucleus innervates the opposite internal rectus indirectly through the intermediary of the third nucleus.

Drs. Bryom Bramwell, Edwin Bramwell, and Chalmers Watson discussed the paper.

Dr. HARRY RAINY and Mr. STILES gave a lantern demonstration of skiagrams, illustrating various bone affections in children.

ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST,
ON THURSDAY EVENING, FEBRUARY 5TH.

The President, Dr. JOHN CAMPBELL, in the Chair.

Dr. Wm. CALWELL demonstrated a method of making a short clinical examination of the stomach and its contents, showing how insufficient the ordinary examination is, and the necessity of extending the stomach with gas, and of a more accurate examination of its contents, including a test breakfast. He demonstrated on a case of dilated stomach, the extent of which could not have been ascertained by the ordinary methods of examination.

Mr. A. B. MITCHELL read a paper based on twenty-nine

OPERATIONS ON THE STOMACH,

including eleven for perforation, with seven recoveries. Referring to these eleven cases he said that the first three were undertaken before the necessity for early operation was generally recognised, and were practically hopeless from the outset; all three died. Eliminating these, he had eight consecutive cases with seven recoveries. As he had recently described these cases he did not dwell on them, but passed on to describe eighteen operations on cases clinically regarded as gastric ulcer. This series included six cases of hour-glass stomach with five recoveries; all five were restored to perfect health after years of semi-invalid life. Further, there were six cases of pyloric obstruction with dilated stomach; four of these were treated by posterior gastro-enterostomy, one by anterior gastro-enterostomy, and one by gastro-duodenostomy. Of these, three died, one from ether pneumonia, one from septic pneumonia (this patient being practically moribund before operation), and one from cicatricial contraction round the new opening. Finally there were six cases unclassified, including one of excision of an ulcer, one of separation of adhesions and gastrostomy, one of simple unfolding of an extensive ulcer without opening the stomach, one of gastro-enterostomy for duodenal ulceration—these four cases all made excellent recoveries—and two cases of exploratory laparotomy where no abnormal conditions were found, though both patients expressed themselves as greatly relieved by operation.

After describing these eighteen cases in some detail, Mr. Mitchell proceeded to sum up the indications for operation. In the first place, he said, all cases where the symptoms point to a mechanical cause should be submitted to operation, as it is perfectly useless to

expect any lasting benefit from drugs. Unfortunately, hour-glass stomach can rarely be recognised beforehand. In dilatation of the stomach, washing out relieves at first, but the relief is only temporary, and operation is the best treatment. In a large proportion of cases no definite indication exists, and it is only when all medical treatment has failed that operation is considered, but in these cases it is important to operate in time, and not allow them to struggle on as chronic invalids till they are too weak to give a fair chance to the surgeon.

Operation is sometimes called for in hæmatemesis but the prognosis in these cases is very bad. Mr. Mitchell recalled two cases he had seen brought into hospital for this condition, and both had died suddenly without operation, though in the light of subsequent knowledge one could see that operation would have been right.

In the discussion which followed the paper, Professor Sinclair made some remarks on the value of different forms of operation, expressing a preference for anterior gastro-jejunostomy. Regurgitation of bile was not frequent, he thought, and need not be held up as a bugbear. As to hæmorrhagic cases, though the surgical rule might be to cut down on a bleeding point, he thought one might proceed to cut down on a bleeding middle meningeal artery with about the same prospects of success. Gastrectomy was, in his experience, liable to be followed by contraction and a state something like hourglass stomach.

Dr. TENNANT discussed the bacteriological aspect of these cases, and the effect which the condition of starvation, in which many of these cases were, might have on the growth of bacteria in the bowel.

Professor SYMINGTON asked, as an anatomist, for information on two points—first, what was a *normal* stomach, and second, did the stomach when dilated ascend as well as descend? He suggested that there might be a physiological as well as a pathological form of hour-glass stomach.

Dr. MCCONNELL, one of the most senior members of the Society, congratulated the younger members on the times in which they were born, and on the wonderful advances in surgery, which to him seemed like "the fairy tales of science."

Dr. CALWELL, replying to Professor Symington's questions, thought that when the stomach reached below the umbilicus it was generally regarded as pathologically enlarged, but it was necessary to remember that myasthenic dilatation often occurred in wasting disease, and such cases would often appear in the anatomical rooms. As regarded the second question, the stomach might be pressed up, but did not enlarge upwards.

Professor LINDSAY discussed the relative positions of the physician and surgeon in these cases, and also the question of the diagnostic value of persistent local tenderness. He would not agree with Dr. Calwell's definition of an enlarged stomach, but considered it pathologically enlarged if the food remained for five hours in it.

Mr. MITCHELL briefly replied to his critics, and thanked them for the kind way in which they had referred to the value of his paper.

The President has issued invitations to the members for a Smoking Concert, to be held in the Medical Institute on Thursday evening, the 12th inst.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD JANUARY, 29TH, 1903.

The President, RUSHTON PARKER, B.S., F.R.C.S., in the Chair.

Dr. BLAIR BELL reported a case of scirrhus of the male breast.

Dr. PERMEWAN reported three cases in which he had successfully removed benign growths from the larynx.

Dr. McDUGALL congratulated Dr. Permewan on the success of his cases.

CASE OF SUCCESSFUL OPERATION ON SEVERED MEDIAN AND ULNAR NERVES.

Dr. NATHAN RAW showed a case in which he had successfully united the severed median and ulnar nerves several months after division. The point he wished to draw special attention to was the return of sensation within twenty-four hours of the operation.

Mr. DAMER HARRISSON had performed many experimental operations with Professor Gotch, and had several successful cases. He had found experimentally that impulses never passed through the nerve before the tenth day. Sensation returned first, then the trophic lesions passed away, motor power followed, and finally electrical reactions were obtained.

Sir WILLIAM BANKS recalled cases, which he showed to the Society, where he had employed the sciatic nerve of the dog and sheep to repair the injured median and ulnar in man. At the Great St. Helens glassworks division of the latter nerve is of no infrequent occurrence, and in former days, when no attempt at primary suture was made, it was very curious what an amount of sensation and motion gradually returned after two or three years. This was explicable on the "loophole" theory, but in Dr. Raw's case the immediate return showed that the nerve current had at once found its way back through the old route. Viewing a nerve in the light of an electric telegraph cable, with each thread of the nerve corresponding to each wire of the cable, we know that, when a broken cable was repaired it was necessary to unite the broken ends of the identical wires, whereas when we joined a nerve,—either immediately or through the intervention of some piece of indifferent tissue, it was not possible to join the identical nerve fibres, and yet messages were sent. Might not the principle of Marconi's wireless telegraphy explain this? Let us suppose the divided ends of the fibres of a nerve to be attuned to each other like Marconi's masts, then any impulses sent along the proximal end from the electrical battery, the brain, can be conceived as travelling through a suitable medium to reach the distal end, without the necessity of intervening fibres (wires) at all.

Mr. G. G. HAMILTON had operated on a number of cases by simply suturing the divided ends, and the results had been quite satisfactory. Two cases were mentioned where division of the nerves was overlooked by chemists. In seven cases a few hours after the divided nerve was sutured sensation returned for about twenty-four hours, and then completely disappeared.

Dr. GULLAND asked as to the appearance of the distal portions of the nerves. After fourteen weeks' separation he would have expected complete degeneration. In this case we could not explain the immediate return of sensation. He also thought a considerable amount of the improved muscular power and movement was dependent on the long flexors, whose nerve supply came off about the seat of section of the nerves, and whose tendons Dr. Raw united at the operation.

Mr. KEITH MONSARRAT had recently a similar case in which sensation was re-established twenty-two hours after operation. He thought this rapid restoration showed that even in the absence of the integrity of axis cylinders the nerve as a whole was capable of conducting sensory impulses, and that the analysis of these impulses took place entirely in the cerebrum.

Dr. Alexander and the President also spoke, and Dr. Raw replied.

Dr. MACFIE CAMPBELL read a note upon bedroom ventilation. After dealing with the changes in respired air, and the rate of change necessary to maintain purity in rooms of varying capacity, he said that a fire in the room was useless unless kept up; the Hinckes Bird system, and Tobin's tubes too, were unsatisfactory in his opinion. Dr. Campbell found the only really satisfactory plan was to have the bedroom window widely open. He found sleep more refreshing, consequently fewer hours in bed were necessary, and getting up a pleasure. That he was never cold at night, and freer from catarrh.

Dr. BARENDT agreed thoroughly with Dr. Macfie

Campbell's remarks. He hoped it would become a tenet of personal hygiene that the air of the bedroom should be as pure in the morning as at night.

Drs. Carter, Permewan, Bushby, Mr. Bickerton, and the President spoke, and Dr. CAMPBELL replied.

OPERATIONS FOR STONE IN THE BLADDER.

Mr. G. P. NEWBOLT read notes of two cases of stone occurring in the female bladder, one removed by litholapaxy, the other by suprapubic cystotomy. He dealt with the methods of removing stone from the organ, and emphasised the fact that vaginal lithotomy may be followed by fistula, and should only be practised on certain rare occasions.

Mr. THELWALL THOMAS, although particularly partial to suprapubic lithotomy, thought that such an operation in adipose females with ammoniacal urine liable to lead to septic cellulitis. He preferred vaginal lithotomy if lithotripsy was impossible.

Dr. BRIGGS thought vaginal lithotomy had many advantages over the suprapubic route in adult females. Abundant evidence now existed in support of this view.

Drs. E. T. Davies, Bushby, and Alexander spoke and Mr. NEWBOLT replied.

CORK MEDICAL AND SURGICAL SOCIETY.

MEETING HELD WEDNESDAY, JANUARY 28TH.

Dr. P. T. O'SULLIVAN, President, in the Chair.

Dr. J. COTTER showed a fibro-myoma of the uterus weighing 13 lbs., which he had removed from a patient, æt. 52, by supravaginal hysterectomy. Menstruation had been regular during the seven years that the tumour had been noticed, and, except for some bladder trouble, there were no prominent symptoms. The patient made a good recovery. Dr. Cotter also read notes of an operation for strangulated hernia in a male infant, æt. 6 weeks. The hernia was of the congenital inguinal variety on the right side. The operation was done by Barker's method, and the patient was discharged cured nine days afterwards. As regards the age of the patient, statistics were given in the "International Text-Book of Surgery" of 100 cases of herniotomy on infants, and in these the youngest patient was two months old.

Dr. PHILIP G. LEA showed a patient suffering from acromegaly. The patient was a married female, æt. 28. For the past three years she had had amenorrhœa. Over a year ago she noticed her hands getting larger, and in a short time had to wear size 8 in gloves. For some time past she could get only woollen gloves to fit her. She wore 10½ men's size in boots. Her height was 5ft. 4ins. The lower jaw was also enlarged, and when her jaws were closed the lower teeth protruded, and were also separated from one another. The patient suffers greatly from excessive perspiration.

Dr. H. R. TOWNSEND read notes of a case of rodent ulcer successfully treated by X-rays, and showed photographs of the patient, an old lady, æt. 72. The ulcer was situated between the eye and tip of the nose on the right side, and had lasted fourteen years, during which time various methods of treatment had been tried without success. Forty-four sittings were given, each lasting from eight to fourteen minutes, the intervals between the sittings being either one or two days. The peculiar feature of the case was that no improvement was noticed while the patient was under treatment, but ten days after the last sitting the ulcer had completely healed.

Dr. W. ASHLEY CUMMINS showed two modifications of Kocher's gland forceps that he had devised. In one there were no hooks at all, and in the other the hooks were much smaller than in Kocher's original forceps, rendering rupture of the capsule of the gland less likely to occur. The blades of the forceps were also inclined to each other at such an angle as not to burst the gland when it was being extracted. Dr. Cummins also showed a fine curved bradawl and needle that he had invented for suturing a fractured patella.

Germany.

[FROM OUR OWN CORRESPONDENT]

Berlin, February 7th, 1903.

At the Society for Internal Medicine, Hr. W. Körte discussed the

INDICATIONS FOR THE SURGICAL TREATMENT OF CHOLELITHIASIS AND CHOLECYSTITIS.

Since the commencement of the nineties this treatment had been in extensive use. Since that period he had himself operated in three hundred cases. The reach of the operation had been over-estimated. Whilst immediate operation had been desired by some surgeons in gall-stone troubles, it had been looked upon by others as the last refuge. The former desired to operate whenever there was a stone in the gall-bladder before it got into the choledochus would be right if the second stage always followed the first. But this was not the case. Even after the most violent attacks a latent stage might come on that might last to the life's end—no recovery it was true, but its equivalent from the patient's point of view. The view had gradually developed that the mechanical condition played a part minor to that of infection. There were typical attacks of cholelithiasis that were set up by inflammation of the gall-bladder only. Then hydrops of the bladder took place from impaction of the stone in the choledochus. Hydrops might exist a long time without giving rise to trouble. So soon as infection took place, however, most serious symptoms came on. Large gall-stones that would not enter the choledochus sometimes occasioned attacks of colic which were also due to inflammatory causes. Also with stones lying in a recess in the duct without blocking it; jaundice and other symptoms appeared due to infection and swelling of the mucous membrane. Especially in the lower part of the duct bacteria were always present, particularly the *Bacteria coli*, which were kept harmless by the constant passage of bile. If any disturbance of this flow through took place, serious symptoms might follow. The presence of gall-stones merely, therefore, did not form an indication for operation, but the kind and degree of inflammation was the guide.

There was another point: Did operation guarantee freedom from the trouble? Certainly not. After trouble might arise in three ways. Either through true recurrences or by pseudo-recurrences, or by retained calculi, or by adhesions. True recurrences were rare, but they did occur. Gall-stones arose from stasis of the bile and from infection. When after cystotomy the gall-bladder almost always became attached to the abdominal wall, kinking of the choledochus might take place and lead to stagnation of the bile. If infection became added we had the condition for a new formation of stones. Stones had also formed around silk threads left in the gall-bladder. A case the speaker related showed that new formation of stones could not always be avoided.

All surgeons would concede that stones might be overlooked. As regarded attachments, the known ready formation of adhesions on the part of the serosa might easily lead to trouble after extirpation of the gall-bladder. The trouble was not serious, however, and it ceased on the separation of the adhesions. The patient's attention should be drawn to this. For the reason given, the speaker was very shy of operating in ordinary cholelithiasis. He operated in such cases at the wish of the patient. He adopted the same attitude in cases of dropsy of the gall-bladder in which, generally, the symptoms were not very acute; in case

they were he proposed operation. In this group, however, internal treatment must be tried first.

There was a second group, however, that belonged to the domain of surgery. This group consisted of such cases as led to permanent invalidism, or were dangerous to life. Here after troubles did not count. The period of time for operation was decided by continued existence of dull pain and discomfort after the acute attack had subsided, the gall-bladder being resistant and tender. The normal gall-bladder could not be palpated—this could only be done when the walls were rigid from inflammation. In spite of suppuration fever was not necessarily present. Suppuration appeared in two forms—acute suppuration and chronic empyema. Empyema should be operated upon as it might at any time pass in to an acute stage; internal remedies were useless. Acute suppuration arose when bacteria found their way in. The inflammation here might be so acute that operation must be resorted to at once, otherwise one would prefer to wait until the attack subsided. The greatest danger in acute inflammation was rupture of the sac, as in a case related by the speaker in which at the operation the gall-bladder was found very tense, containing numerous stones and having at one spot an ulcer almost ready to burst. He had operated in nineteen cases of acute empyema of the gall-bladder. If the jaundice present did not disappear, this was owing to inflammation in the deeper bile passages or from a stone being impacted in the choledochus. The choledochus stone was a pressing indication on account of the danger of cholæmia and ascending cholangitis with abscess of the liver. The operation was not easy and it had its risks. In the absence of acute symptoms, six to eight weeks might be awaited. In one case the speaker found pus in the choledochus even after five weeks.

A not unfrequent complication was carcinoma of the gall-bladder. Along with it empyema of the gall-bladder was often found. In cancer of the gall-bladder calculi were almost always found. When the flow of bile was hindered by a tumour of the pancreas, operation did not afford much prospect. Here cholecystenterotomy might be performed, but the contents of the intestine might flow backwards and lead to abscess of the liver.

As regarded operation the fundamental principle was to make the field of operation accessible. If the gall-bladder was seriously diseased, it should be extirpated. The deeper bile passages could only be inspected in this way. Here also was frequently met with infection, and then drainage of the choledochus was to be recommended.

From all that had been said it would be evident that the time for operation must be determined by the individual features of the case.

Austria

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 7th, 1903.

[MULTIPLE CARTILAGINOUS EXOSTOSES.]

GRUNFELD, at the Gesellschaft, exhibited a boy, æt. 10, with multiple cartilaginous exostoses distributed over the entire body, the ribs, sternum, scapula, humerus, wrists, femur, tibia, &c., being involved. The tumours were of a bony hardness, immovable, and covered by unaltered skin. The child had every symptom of rachitis, such as caput quadratum, angular teeth, &c., while its length and weight were much under the average for its age. The left arm was one centi-

mètre, and its leg two centimètres, less than the right in length. The Röntgen rays revealed a larger number of smaller tumours than was observed on the surface, and, as Virchow has shown, situated at the diaphysal ends of the bones. These growths had a spongy structure with irregular trabeculæ, somewhat hard and dense on the upper surface. The shortening of the extremities with the enlargement at the epiphyses gave an abnormal appearance to the limbs.

The histological examination of the tumours confirmed the opinion of spongy bone bound together by a hyaline cartilage.

Kienböck showed a similar case of multiple exostoses, of which he had counted eighty. On moving the shoulder-blade loud crepitations could be heard at a distance, evidently due to the friction of one of these tumours with the scapula, the radiogram showing two such tumours.

The peculiarity in this case was that the outline under the Röntgen rays was much less than under actual palpation, the difference being due to a thick cartilaginous covering over the exostoses. There was also diffuse enlargement around the diaphyses of a porous nature. This spongy condition of the enlargement, which was even free round the joints of the feet, is a pathological distinction that may be utilised in diagnosing such tumours from chondroma, sarcoma, or carcinoma.

PANCREATIC NEOPLASM.

Lotheissen brought forward an elderly woman whom he had operated upon for a pancreatic tumour which had determined duodenal stenosis with intense icterus.

Gastro-enterostomy and cholecystoduodenostomy appeared to have given excellent results.

The patient commenced to complain about the beginning of last summer of great pain in the abdomen. This was associated with extreme emaciation. In September she began to vomit, and the whole surface of the body became icteric. On palpation a tumour about the size of an apple could be felt in a dull area over the site of the gall-bladder, tender and not moving with respiration.

The feces were acholic, no steatorrhea, nor any trace of melituria was noted. Chemical examination of the stomach contents confirmed the absence of hydrochloric and free lactic acid.

On October 13th, laparotomy was performed and the pancreatic tumour removed. Immediately after the operation the icterus disappeared, and strength returned. Since then the tumour has returned with periodical pain, but in the absence of ascites it may be assumed that the case is not one of carcinoma.

RÖNTGEN RAYS AND ULCERATION.

Kaiser demonstrated an interesting case of blistering of the upper arm following the use of the Röntgen rays for epilation in the case of a female.

She had undergone twelve sittings of ten minutes each, she felt no pain and there was no sign of dermatitis before the ulcer appeared, which was 14 ccm. long and 6 ccm. broad. After this he applied the blue rays daily for one hour to the ulcer, which had rapidly healed, and he thought they had reduced the pain. He always warned patients whose vanity prompted them to have hypertrichosis removed that the Röntgen rays were not free from a certain amount of danger. He then exhibited a lead speculum which he used for concentrating the rays which obviously diminished if not, indeed, altogether prevented destruction of the surrounding tissues.

Iselberg was of opinion that the ulcer did not improve under the influence of the blue light, and opined

that the healing would have taken place quite as rapidly without it.

Exner admitted the influence of lead in concentrating the rays on one spot and thought a great advance would have been secured if the diffuse rays could be better concentrated.

Kenbock entirely concurred with Kaiser in his strictures on patients for demanding epilation by the Röntgen rays, as there was considerable danger. He could not agree with him, however, in the benefits to be derived from the use of a lead speculum, as it was quite worthless. A lead plate or cylinder was quite sufficient. The action of the blue rays in promoting healing was also a very hypothetical assumption.

Freund confessed that he was not such a pessimist concerning the use of the rays in epilation, if after each sitting sufficient time were allowed for the parts to recover. In many cases the removal of hypertrichosis was an absolute necessity, such as in young females who had to earn their living and whose engagements depended very much on their outward appearance.

Kaiser, in reply, admitted the want of confirmation in respect of the value of his lead speculum, but he was convinced that the blue rays had a beneficial effect upon the healing of such ulcers.

Hungary.

[FROM OUR OWN CORRESPONDENT.]

Budapest, February 5th, 1903.

AGURIN: A NEW DIURETIC.

In a paper, "Agurin: a New Diuretic," Professor Purjesz draws attention to the advantages this new agent possesses over the other theobromin preparations. He contends that it is less irritable to the mucous membrane of the stomach, and contains more theobromin (about 60 per cent.) than the other preparations; it has also greater diuretic action, on account of the large proportion of acetate of soda found in it.

Dr. Purjesz investigated the action of agurin on thirty-two patients, administering it generally in the form of powder. To those patients who could not take it in this way it was prescribed in fluid form prepared thus:

R. Agurin 10·0 grammes ;
Aq. menth. piper ;
Aq. dest. aa. 100·0.

Four tablespoonfuls to be taken daily.

The disagreeable taste which agurin, even in this combination, possesses can be overcome by the patient eating a small piece of sugar or chocolate.

Summarising his observations on agurin, he gives the following results of his investigations:—

As a diuretic, agurin is principally effective in œdema, caused by heart disease, but it is less useful in dropsy caused by portal obstruction. In exudates of inflammatory origin or in renal diseases it is of no avail.

It has no direct influence upon the blood pressure, its action depending on the heart function, and it fails to act when the blood pressure is low, just as in other diuretics. Against its valuable properties certain disadvantages must be mentioned—its objectionable taste which it is difficult to disguise, and occasionally it has been found to cause digestive troubles.

REMOVAL OF A FOREIGN BODY IN THE URETHRA.

At the recent meeting of the Royal Hungarian Medical Society, Dr. Bako related the case of a watchman, who stated he had inserted in his urethra a small wax-candle two days previously, which slipped into the bladder, causing pains at the end of the act of micturition in the

perineal region. Otherwise, he had no pain, and could retain his urine for four hours.

Mr. Bako immediately after washing out the bladder, began to remove the foreign body, and for which he first used a lithotripter furnished with blades; but this failing, he made a trial with a thicker one furnished with "fenestra," with which he succeeded.

The removed foreign body was a piece of wax candle 10 ccm. in length, and 11 mm. in thickness.

After the operation, the bladder was washed out daily; urine for a few days remained somewhat bloody; and the patient felt a little pain along his urethra; all these have since ceased, the urine is entirely clear, and the patient left the hospital entirely cured on the tenth day.

RESECTION OF THE LARYNX.

Professor Havratil demonstrated on a patient, æt. 45, on whom he performed tracheotomy a year ago, and this year resection of the larynx became necessary on account of cancer of the left side of that organ. The operation was performed according to the usual method. A portion of the right side of larynx was also dissected. The patient now breathes through a cannula, and his voice is very well heard. He has gained twenty pounds in weight since the operation, and there is at present no trace of recurrence.

Dr. Donogany related a case of

CORNU CUTANEUM IN THE NOSE.

The patient, an agricultural labourer, æt. 36, noticed a year ago, on the left side of the nasal septum a small growth, which grew gradually until it obstructed the breathing passage almost entirely.

• The patient had neither pain nor bleeding. When examined, a considerable part (covered with scab) of the growth the size of a hazel-nut was hanging down. The portion remaining within the nose had a greyish-white surface, covered with villous appendages; anteriorly, it started from the septum cutaneum and the base of the nasal cavity. After operation it became clear that the site of adhesion occupied an area of about the size of a shilling in the nose itself. After removing the growth a little hæmorrhage set in, which ceased on touching the bleeding spot with cotton dipped in chromic acid. The microscopical section of the growth showed it to consist almost entirely of epithelial cells. The connective tissue abounded in dilated vessels. On the thickened epithelium could be distinguished two layers—a lower one, similar to the common epithelia, and an upper one, which was considerably thickened, and different from the ordinary type, because its cells had been transformed by the process of parakeratosis setting in. Mr. Zwilling remarked that he had often met such thickenings the surface of which became keratous on account of the influence of chronic irritations.

The Operating Theatres.

GUY'S HOSPITAL.

FRACTURED DISLOCATION OF THE UPPER END OF THE HUMERUS.—Mr. ARBUTHNOT LANE operated on a man, æt. 60, who had sustained an injury to his shoulder twenty-five days before admission. The radiograph showed that the head of the bone was displaced forwards, it having been broken off the shaft through the surgical neck in such a manner that although most of the fracture was transverse, there projected backwards and outwards from the upper fragment a spike of bone that had been torn off the shaft. The upper extremity of the lower segment was seen to be displaced directly

inwards, and by no amount of manipulation could the fragments have been brought into apposition. A vertical incision was made through the anterior limit of the deltoid, and another along the muscle's attachment to the clavicle and acromion, this portion of the muscle being turned outwards and backwards. The seat of fracture was then thoroughly exposed; the ends of the bones were found to present no change whatever, although an interval of nearly four weeks had intervened between the injury and the operation. The only difficulty experienced in the operation resulted from the very frail condition of the bone, the texture of the upper end being soft, while the compact layer of the lower fragment was very thin. When the fragments had been placed in apposition, they were perforated by a drill and a stout silver wire was passed through them and twisted firmly. The margins of the deltoid were sutured together and the skin wound closed. Mr. Lane said that any treatment other than operative would have been hopeless in the extreme; indeed, this course had been pursued up to the time the case came into his hands. He thought that anyone who has had any experience at all of the treatment of these injuries (if the word treatment can be applied to the policy of drift which is almost universally adopted) knows how absolutely futile are any means other than operative. Mr. Lane also called attention to the fact that no naked eye change whatever had taken place in the fragments, and that any process of massage or movements would be ridiculous under these conditions. As far as the operation is concerned, the risks, he considered, were *nil*. The subsequent progress of the case was uneventful.

FRACTURE OF THE ASTRAGALUS.—The same surgeon operated on a man, *æt.* about 22, who, several months before, had fallen about eight yards upon his feet and had sustained a severe injury to the right foot, which had been treated by splints and massage with the result that the foot was fixed in a position of moderate extension. The condition was accompanied by so much pain and disability that the patient desired that his foot should be amputated. He was, however, induced to submit to an operation undertaken with the object of saving as much of the foot as possible. An examination by means of the X-rays suggested that the astragalus had been broken in two; the posterior fragment having been detached was displaced upwards and had become attached to the posterior surface of the lower end of the shaft of the tibia. It was quite clear that at this stage of the proceeding no operative skill could have replaced the fragments in apposition and obtained a movable joint. Mr. Lane therefore determined to perform some operation by means of which the lower ends of the tibia and fibula would be united to the bones of the foot. Consequently he exposed the seat of injury from the inside, and, after chiselling off the displaced portion of the astragalus, he chiselled off the lower ends of the tibia and fibula immediately above the relics of the astragaloid facet; he then chiselled through the *os calcis* and adjacent bones till he had obtained a surface to accommodate the lower end of the tibia; this having been done, the bones were retained immovably in position by means of a screw which was passed from within downwards and outwards through the tibia and tarsus. The subsequent progress of the case was uneventful, but the mechanical advantages gained by the operation cannot be gauged till the patient is able to use the limb.

FRACTURE OF THE TIBIA AND FIBULA.—The same surgeon operated on a man, *æt.* 30, who had sustained a fracture of the tibia and fibula some months previously, and who was completely unable to use his foot because

of the great pain he experienced in doing so. The foot was fixed in a position of moderate extension, and there was an almost complete forward dislocation of the lower end of the tibia. The radiograph showed that the internal malleolus, with the inner and back part of the shaft of the tibia, had been broken off and had become attached to the dislocated tibia at a level much higher than normal. The fibula was broken about three inches above the ankle-joint, the fragments being overlapped. The inner part of the ankle-joint was exposed the dislocated tibia was freed so as to allow of its being placed in its normal relationship to the astragalus, the lower fragment of the tibia was chiselled off the shaft, and was fixed by two screws as perfectly as was possible in its normal position; before this could be done it was necessary to expose the fracture of the fibula, to chisel through the junction, to get the ends of the fragments into apposition, and to retain them by means of stout silver wire. Mr. Lane was hopeful that he would obtain a fairly satisfactory result from the measures he had adopted; he could only regret that surgeons were satisfied to muddle along in the manner which these cases illustrated so well. As time went on he found it more and more impossible to reconcile the statements which had been, and are still, made as to the success of the treatment of these cases by means other than operative. The subsequent progress of the case was uneventful.

OPERATION FOR RECURRING ATTACKS OF OBSTRUCTION OF THE CÆCUM AND ASCENDING COLON AT THE HEPATIC FLEXURE, THE RESULT OF CHRONIC CONSTIPATION.—The same surgeon operated on a girl, *æt.* about 26, who had been under observation with recurring attacks of a condition which had been diagnosed as typically appendical, and she had been under the care of a medical man of great skill and experience; this Mr. Lane mentioned to show how closely an appendical attack may be simulated by this condition of acquired obstruction, the result of habitual constipation, to which he called attention for the second time in the *Lancet* of January 17th, 1903, in a paper entitled "Chronic Obstruction of the Cæcum and Ascending Colon," read before the Sydenham Medical Society on November 20th, 1902. The present patient illustrated in a typical manner, he said, the condition of interference with the free passage of intestinal contents through the hepatic flexure to which he drew attention in that paper. He then proceeded to open the abdomen by an incision running over the cæcum and ascending colon; he divided the adhesions and newly-formed mesentery, so as to allow the hepatic flexure of the colon to come forward and to remove the obstruction for the passage of fæces through it. Mr. Lane said that this obstruction was brought about by the development of a mesentery which is attached to the outer surface of the cæcum, ascending colon, and hepatic flexure. He pointed out that should the cæcum become at all distended its movement in an inward and upward direction brings about a kink in the hepatic flexure which renders the passage of fæces through it extremely difficult and sometimes impossible, thus producing the symptoms of intestinal obstruction. This chronic obstruction of the flexure results in a progressive distension and hypertrophy of the cæcum. Another point to be remembered, he said, was that on account of the intimate fixation of the colon to the kidney and to the abdominal wall outside it, and to the nerves in that situation, the pain felt along the distribution of these nerves and the tenderness on pressure below the last rib in these cases may be more typically renal in character than they are in the case of stone in the kidney. Mr. Lane

also said he was certain that in a large proportion of cases of so-called appendicitis the primary factor in the production of inflammation of the appendix is obstruction of the hepatic flexure, and that the trouble in the appendix is merely a secondary manifestation.

DIAGNOSIS AND TREATMENT.

FORMERLY medicine was regarded as essentially the art of *treating* disease, but as physical diagnosis has improved and pathological knowledge been rendered more precise, a tendency has shown itself to relegate mere treatment to a position of secondary importance, not only in the curriculum but also in practice. Yet diagnosis and pathology are branches of knowledge which possess any importance at all only as guides to successful treatment, and when they elbow it out of medical practice they become sterile acquisitions, like sundry lost documents, “of no use to anybody but the owner.” This tendency to neglect the study of therapeutics, for which examining boards are very largely to blame, may explain how it is that practitioners possessed of the most ordinary qualifications, and by no means distinguished for their professional attainments, find favour with the public and obtain a popularity denied to many of their far more talented brethren. The fact is simply that their minds, not being exclusively occupied by delicate questions of diagnosis and the inter-relationship of clinical symptoms with particular morbid appearances, are free to turn their whole attention to remedial measures which are what the sick public yearn for, irrespective of their efficacy. But although we are expected to treat, even when treatment cannot by any possibility be curative, it must be remembered that treatment, palliative or curative, is the proper aim and the very *raison d'être* of the physician, and that much can be done to relieve suffering and prolong life, if nothing more.

Even the homely *placebo* is not without its moral value, and the public are not unnaturally impatient of the attitude of the practitioner who, having carefully thought out his diagnosis, considers that he has done all that can reasonably be expected of him. The therapeutical scepticism which is so much *à la mode* among practitioners of the present generation betokens ignorance of the resources at their disposal, an ignorance which the trend of modern medical education has done much to foster. We have only to place ourselves in the mental state of a patient who seeks relief. Well may he ask, Of what use is all this science to me if, after all, it is powerless to do me good? He knows that drugs have power and that, intelligently used, they have power for good. A correct diagnosis must precede treatment, but it does not dispense with the need for treatment. We have to take human beings as we find them, and since the average patient will only take advice as to hygiene, sanitation, and habits of life when washed down with a little medicine, it is politic to avail ourselves of the resources of the pharmacopœia to bring about a return to health. This is a matter in which the General Council of Medical Education might well take the initiative. Teaching and examining bodies have been allowed to whittle down the standard of requirements in therapeutics and materia medica almost to vanishing point without a protest. We have only to glance at the questions set by almost any examining board to become cognisant of the trivial importance now attached to this, the Alpha and the Omega of medical practice. The result is that practitioners no longer know what to prescribe or how to prescribe it, whence the favour accorded to ready-made products due to the ingenuity of manufacturing chemists. The successful practitioner is he who unites theory with practice and diagnosis with treatment, and the punishment of therapeutical scepticism will be meted out to them as soon as they launch forth into practice, when they will find that patients ask for deeds, not words.

SHELLFISH AND ENTERIC FEVER.

THE recent outbreak of enteric fever in the South of England, attended as it was by the deaths of several distinguished men, has naturally created a deep impression upon the public mind. The moral has since been strengthened and enforced by the fortnightly report, dated January 17th last, of Dr. Collingridge, the Medical Officer of Health for the City of London, who has dealt with two small but distinct epidemics of shellfish typhoid in the Metropolis, and with the larger outbreak above alluded to. In both of the former instances the infection was conveyed by shellfish, either oysters or cockles. The cockles were obtained from Southend, and their contamination has since formed the subject of exhaustive inquiry. Professor Klein found numerous bowel bacilli in these Southend cockles, both raw and cooked. This fact conclusively proved the existence of sewage contamination, in spite of negative results so far

as the actual detection of the *Bacillus typhosus* itself. The presence of bowel organisms is hardly to be wondered at, inasmuch as it was customary to collect the cockles from the Maplin and Blythe Sands, situated in the estuary of the Thames and to deposit them for a day or two in the creek at Southend in order to free them of sand. The condition of the water in the creek is sufficiently described by Dr. Collingridge in the statement that "the small amount of water in the creek at the end of the ebb tide was practically sewage." In short these shellfish were stored under conditions of the most filthy and revolting nature that could possibly be imagined. "Cooking" does not sterilise the shellfish, owing to the fact that the process is of a most perfunctory nature. The cockles are simply plunged in a mass into boiling water, which cools down before sufficient heat has penetrated the interior of the shells to destroy the vitality of organisms contained therein. If properly carried out—that is to say, if the boiling be continued for three or four minutes—the cockles become sufficiently sterilised, although not so marketable from the vendor's point of view. We may here ask what is the use of publishing the details of highly technical bacteriological examinations in reports intended for the use of laymen. The public learn from their newspapers that coli-like and typhoid-like bacilli have been found, that one variety of *Bacillus coli* was extremely motile and cylindrical, but gave no sign of agglutination with typhoid bacilli in 1 in 20 in one hour. The man in the street can only receive that sort of information with a gasp of astonishment at the profundity of scientific knowledge and the enormous gravity of the dangers attached to the eating of shellfish. He will read with avidity the account of the testing of fluid from suspected oysters by sterile culture media made of phenolated broth, of MacConkey's formula (namely, litmus, glucose, taurocholate of soda, and peptone in water), and so on. We fail to see the object of the publication of a mass of costly printed matter of this kind. What would be thought of the physician or surgeon who thus published an account of the methods whereby he arrived at a diagnosis? We fail to see why a medical officer of health should not support his case by stating generally that a bacteriological examination revealed the presence of living organisms derived from sewage, and that the investigation had been conducted by a recognised scientific authority. The present system appears more or less calculated to bring a most necessary branch of scientific investigation into ridicule. Upon learning the facts of the Southend cockle infection the City sanitary authority communicated them to the Worshipful Company of Fishmongers, who have extensive powers over the fishing industry. The Company immediately forbade the stowing of any more cockles in Southend Creek. It was next found, however, that shellfish taken from the Maplin and Blythe Sands were also contaminated with sewage, a fact since confirmed independently by the Company. The sands, however, appear not to have yet been closed to the fisherman. As to

oyster contamination, the result of bacterioscopic examination of samples from various parts of the Kingdom has revealed widespread and serious pollution. The obvious result of these observations must sooner or later be the legislative control of the shellfish supply of the United Kingdom. For the present the oyster trade is practically ruined, and the people deprived of a valuable article of food. The irony of the situation lies in the fact that the distribution of disease by shellfish is absolutely preventable, and that the facts of the case have been known to demonstrators for several years past.

OBJECTIONABLE ADVERTISEMENTS.

THE present is said to be a scientific age; it might with greater truth be designated the day of advertisements. We do not by any means seek to decry all such as unworthy or inexpedient; indeed, in medicine, as in the other professions, we are of opinion that there is not only a legitimate but a desirable form of advertisement which every honest and ambitious worker in the highest interests of his work and for the benefit of the community should not hesitate to avail himself of. But there are many forms of advertisement which not only break the rules of customary etiquette but offend the ethical sense of all conscientious practitioners. A striking example we find in the current issue of a widely circulated weekly:—"English medical man, now on the water, returning from South Africa, wishes to meet with a Methodist capitalist (man or woman) as partner to aid in introducing to English public a remedy he has prescribed and used daily in his practice in Rhodesia, Natal, and Transvaal with unvarying success. There is at the present day no more profitable investment than a popular medicine. An investment of £1,000 may be expected to realise £200 and insure the capital and less sums in proportion." We venture to commend this remarkable advertisement to the consideration of the Medical Council and the editor of *Truth*. Our attention has also been drawn to a paragraph in the February number of *Womanhood*, in which the editor-ess claims: "With the exception of the *Lancet*, however, I believe mine are the only papers the advertisements for which are subject to editorial censorship." Immediately opposite this interesting announcement is an advertisement labelled "Priceless to ladies," and extolling the virtues of "Pennyroyal and steel pills," which "will remedy all defects—are a balm to the tortured body—quickly correcting all irregularities, removing all obstructions, strengthening the system, relieving of all anxiety." This publication claims to be "The Magazine of Woman's Progress and Interests," but in spite of "editorial censorship" we regret that some stronger power is not available to arrest this introduction of incitement to abortion into our English homes. It is clear that medical men should be careful to explain to their patients when opportunity offers, the sin or folly which must almost necessarily flow from dealings with advertisements of the type we have endeavoured to indicate.

Notes on Current Topics.

Consultation with Homœopaths.

THERE are not many questions of medical ethics which have been more debated than that as to the attitude members of the profession should adopt as to meeting homœopathic practitioners in consultation. It is naturally of more interest in America and the Colonies, where homœopathy flourishes with higher head than at home, but nevertheless the difficulty may arise for any of us at any moment, and it is well to have a clear course of conduct laid down in advance. The received opinion is that, where the object of consultation is a question of diagnosis of *surgical* treatment no objection should be raised to meeting a homœopath; but where the sole question is one of *medical* treatment consultation should not be held. The reason for the distinction is, of course, very obvious, as the homœopathic heresy is concerned with medical treatment only, and entirely vitiates that. In New Zealand, although the rule of ethics is maintained as we have stated it, an incident has recently occurred which emphasises the necessity of members of the profession having clear ideas on the subject. A homœopath while attending a case of labour found that in his opinion perforation of the head was necessary. Not having a perforator with him he despatched a messenger to procure another medical man's assistance with the necessary instrument. The messenger called on several men, none of whom possessed a perforator, while one, in addition to making this statement, expressed himself further as to the impossibility of his assisting a homœopath. Unfortunately the patient died without the necessary aid, and something of a public scandal has been created. Apart from the impropriety of refusing aid in an urgent case under any circumstances, the attitude of the gentleman in question was undoubtedly wrong in this case, and we have no doubt it would have been quite different had he had clearly before his mind the distinction we have endeavoured to bring out.

Semi-Teetotalism.

APATHY on the one hand and fanaticism on the other have done much to hinder the elimination of alcoholism. While custom and, we venture to think, the influence of scientific teaching, to some extent, at least, has lessened the prevalence of drunkenness among the educated classes, every physician is well aware that alcoholism in one or more of its protean forms exists to an extent that seriously menaces the health and well-being of the country. Much of the degradation of tissue brought about by the action of alcohol and other deleterious constituents in many forms of intoxicating drink arises from the pernicious habit of nipping between meals, and indulging at almost all times in spirits and liquors having a high percentage of alcohol. The movement which the daily papers have recently widely paraded as semi-teetotalism is deserving of medical approval, since it is in accordance with sound hygienic principles. Undoubtedly many of the influences

of modern life tend to encourage irregular forms of drinking, and any movement which aims at discouraging the chronic tipping now so prevalent among women and many business men, and limiting the imbibition of alcoholic beverages to meals, should receive support on physiological grounds. We understand Lord Roberts has accepted the presidency of this new cult. Doubtless, some of the total abstainers will smile at this "semi" society and seek to encourage semi-teetotalers to drop the prefix and erase the hyphen, but for ourselves, and we venture to think we may speak for medical men generally, every effort which on rational and scientific lines aims at arresting alcoholism and seeks to restore the alcoholic will secure the approval and support of all thinking men.

The Prophylaxis and Treatment of Colour Blindness.

It is customary to regard colour blindness as a visual defect of congenital origin, which cannot be prevented, and which does not admit of treatment. Experience, however, teaches us just the contrary. There may be, it is true, individuals in whom the colour sense is altogether absent, but they are few and far between. The fact is that while the sense varies within very wide limits, most persons possess, in a greater or less degree, a perception of colours which only requires to be cultivated. It is a remarkable fact that the defect is much more frequently met with in males than in females, doubtless because from an early age girls are unconsciously trained to exercise their judgment in this respect. Out of 10,000 men, 369 were found to be thus affected, while only nine women failed to pass the test; and the proportion among savage men is less than among civilised people. Moreover the training of boys in the recognition of colours markedly diminishes the proportion of colour-blinds, but, to be useful, the training must be commenced at an early age, otherwise a sort of colour amblyopia may be developed, rendering instruction useless. The lesson to be learned is that by proper cultivation, even a very moderate colour sense may be developed to a very useful degree of colour perception, though the limits of cultivation in this direction cannot as yet be accurately defined.

Coroners' Juries and Hospitals.

CORONERS' juries seldom fail to avail themselves of opportunities to advise hospital authorities as to the way in which such institutions ought to be managed. It not infrequently happens that their views embody public opinion, but the advice tendered by them is not always of this high quality. In the case of a woman who applied at St. Thomas's Hospital last week on account of a burn, admission was refused by the medical officers on duty, her condition not being thought such as to require treatment as an in-patient. It turned out, however, that she was suffering from advanced renal disease, which, in association with the shock of the burn, determined a fatal result at the infirmary, whither she had been conveyed. Obviously, if

the state of her kidneys had been known, a different view would have been taken, but there seems to have been nothing in her appearance to suggest this complication. The jury, however, expressed the opinion that the question of the admission of patients should be dealt with by "the more experienced officials," and although in principle the advice is sound, in practice it must be difficult to obtain the "highest authority" in respect of every person who applies for treatment in the casualty department. In another inquest, held by Mr. Troutbeck, a man who had been knocked down by a horse was taken to the nearest hospital whence, as there was no indication of cerebral injury, he was removed to the infirmary. He died subsequently, and, post mortem, a fracture of the skull was discovered. In this case the jury thought that cases "ought always to be kept under observation until symptoms had developed," a well-meaning rider which has the drawback of being unworkable, since it would mean keeping every victim of an accident for a week or so in order to make sure that he had not sustained any internal injury.

The Ballachulish Quarry Medical Dispute.

THE oppressive measures taken by the directors of the Ballachulish Quarry to obtain the enforced retirement of Dr. Lachlan Grant, on the ground that he agreed to leave the village in the event of his contract with the company being determined, has led to further developments of a kind likely to involve the company in considerable trouble. The men have cancelled the arrangement providing for medical attendance in order to obtain a free hand in dealing with the question, and advantage has been taken of the suspension of diplomatic negotiations to advance certain claims other than the liberty to select their medical adviser. Failing satisfaction, they threaten an exodus *en masse*, a contingency which may lead the directors to reconsider their position.

The Redistribution of Hospital Accommodation.

THE idea of providing for a more equable distribution of hospital accommodation in the Metropolis has much to commend it, but, unfortunately, to carry it into practice would entail the expenditure of an enormous amount of money. Of more immediate importance is the proposal to bring about the amalgamation of the numerous small special institutions. Not only could this be effected without any outlay of funds, but it would result in an immense economy in the cost of administration. Before attempting to realise this project, however, it will be necessary to place some restrictions upon the liberty at present enjoyed, and even abused, to dub any private house a hospital, and on the strength of the description to appeal to the charitable public for funds; in other words, public appeals for money should only be permitted by duly authorised bodies. The unrestricted creation of private venture hospitals is prejudicial to the financial stability

of our large general hospitals, and is inimical to the interests of the profession, since they are for the most part the preserves of groups of enterprising practitioners. It is obvious that the multiplication of hospital buildings, each with its staff of paid lay and medical officers, must seriously deplete what may be termed, *en bloc*, the hospital exchequer. Moreover, the competition for patients tends to pauperise the community by accustoming its members to gratuitous medical attendance, irrespective of their social status.

Seats for Shop Assistants.

THE humane tendencies of the present age are in many instances happily guided by the teachings of modern science. No better illustration of that beneficent fact could be found than the passing of the Seats for Shop Assistants Act in the year 1899. The main feature of that measure was the compulsory provision of seats for assistants in shops. In spite of its existence, only last week a London tradesman was fined for failing to provide a seat behind the counter for his female assistant. The offence was proved by a lady inspector of the County Council. The defendant, upon his attention being called to the omission, pulled a box from beneath the counter, and suggested that would do to sit upon. Speaking generally, it would be well if local authorities were to inquire a little more closely into the administration of the Shop Seats Act in various parts of the kingdom. As the medical profession is well aware, the bad effects of prolonged standing are shown in manifold and disastrous ways upon the bodily framework of shop assistants. Flat-foot, varicose veins, swelling of legs, hæmorrhoids, and various circulatory disorders are common results, to say nothing of many uterine troubles originated thereby among women. It is to be remembered, moreover, that the habits and surroundings of the average shop assistant do not conduce to a high standard of physical resistance to adverse conditions. Indeed, the institution of shop seats may be regarded chiefly in the light of an instalment of much-needed reform in other directions.

Election to Hospital Appointments.

IN the making of appointments to a hospital staff we believe that there should be the greatest possible publicity. If the post is open to competition care should be taken that sufficient notice is given by public advertisement, both in medical and lay papers, so that all candidates shall have a fair chance of making their claims known to the electors. Without such care the electors rarely have an opportunity of selecting the most suitable applicant. We are instigated to make these general remarks by consideration of the method pursued in making a recent appointment of physician to the staff of one of the Dublin hospitals. In this case no vacancy was expected for some months to come, and the profession were not in any way aware of the intention of the Board to take time by the forelock. We understand that only one advertisement of the appointment ap-

peared, and that in a paper not very generally read in medical circles. Under the circumstances many gentlemen who had intended to become candidates, were precluded from putting their claims properly forward, and others knew nothing of a vacancy existing until they learned from the daily papers that it had already been filled. We, of course, do not in any way suggest that the actual appointment made may not be an excellent one, but we think the method of making it leaves much to be desired.

Municipal Laboratories and Public Health.

FROM the point of view of public health nothing is clearer than that the prompt diagnosis and isolation of cases of infectious diseases is of the utmost importance. In order to ensure the necessary promptness and accuracy many of the larger cities have in recent years established bacteriological laboratories where medical men can have skilled investigations conducted free of charge. For instance, in Manchester, examinations are made of pathological material in cases of suspected phthisis, diphtheria and other diseases, and medical men are given facilities for supplying suspected blood in order to have the Widal test carried out where necessary. But, in this direction, as in most others where municipal enterprise is concerned, we lag behind our cousins beyond the Atlantic. In the State of Massachusetts we find that there is hardly a town of twenty thousand inhabitants which has not its fully equipped bacteriological laboratory. It is surely time that our municipal authorities recognised that funds spent in the prevention of disease are very far from being wasted.

The Care of Lunatics.

How to face the question of increase in lunacy is somewhat difficult. It there were no interests at stake beyond those of the lunatic an easy solution would be found in multiplying asylums, but there are other considerations demanding attention—the cost of maintenance and the burthen on the industrious tax-paying population. While it is a duty to protect and provide for the insane poor, it should be done at as small a cost compatible with attainment of the object in view. Each individual costs as much as serves perhaps for the maintenance of the patients' family, and in view of many of the asylum inmates being quiet and inoffensive, the question arises whether they could not be kept at home under some supervision from the asylums, who would detect abuses and give advice when necessary.

Curious Views of a Coroner.

MR. T. P. BROWN, the coroner for the Ksighley district, holds that "if a medical man cannot tell anything without cutting up a body and annoying the whole street and the relatives," his services should be dispensed with as much as possible. By way of further defining his attitude to the medical profession, he added, on the occasion of an inquest on a child who had died from the

effects of scalds, that "he wanted to get a bit of sense out of the doctors for a guinea, and if he could not he would do without them." With such a coroner inquests are not likely to contribute much information towards elucidating the cause of death, and we do not envy the fate of practitioners who are called upon to assist him.

An Anti-Vaccinator Brought to Book.

A MR. HILLS thought fit, a short time since, to bring certain serious charges against Dr. H. T. Bryan, the public vaccinator to the Medway Board of Guardians, alleging, among other things, that the latter had enticed children into his surgery for vaccination without the consent of their parents, and that he had certified as due to erysipelas the death of a child who had died from vaccination. A few days later it seems to have occurred to Mr. Hills that his allegations might be construed to be libellous, and he accordingly wrote the clerk that unless the communication were dealt with in committee he would hold the Board responsible for the publication thereof. He followed up this letter by one in which, "owing to unexpected developments," he expressed the desire to withdraw his allegations. Naturally the Board declined to assent to their withdrawal, and referred the matter to the Local Government Board. A committee of inquiry was, however, appointed, who reported that "these charges have been brought recklessly and with no reasonable or probable cause and . . . that there is distinct evidence of malice in making them." The Board accordingly passed a resolution to the effect that the charges "were untrue and ought not to have been made," adding a rider directing the clerk how to deal with any future communications from the same source. As the case is not unlikely to be heard of again elsewhere, we abstain from comment beyond the remark, addressed to anti-vaccinators in general, that it is a very serious thing to bring unsubstantiated charges against a public official, and that the doing so may land the delinquent in a very disagreeable situation.

Lemon Juice as a Prophylactic of Typhoid.

THERE is good ground for believing that lemon juice exerts a marked germicidal action on the typhoid bacillus, and probably on sundry other pathogenic germs, such as the comma bacillus, for instance. The public have therefore been solemnly advised to deluge oysters with lemon juice before consigning them to oblivion, and to add two teaspoonfuls thereof to each tumbler of suspected water before drinking the same. By extension it follows that lemon squashes constitute a salutary, as well as refreshing, beverage at all seasons, and that the addition of a slice of lemon to the nocturnal grog may destroy such germs as have not been rendered oblivious of their surroundings by the alcohol. Seriously, however, such advice savours of the ridiculous. Admitting that lemon juice kills the germs of typhoid, the fact remains that it is not a case of "happy dispatch." Bacteriological experiments show that the addition

of four per cent. of lemon juice to infected culture bouillon only proved effectual after the lapse of from twenty to twenty-four hours, so that, although the lemon is generally supplied with oysters at table, the intending consumer can hardly be expected to wait twenty-four hours to begin his meal. Moreover, the germs are not distributed over the glistening surface of the succulent bivalve, they lurk unperceived and unsuspected within its alimentary canal, awaiting a favourable opportunity to sally forth on their work of destruction. The only way to disinfect a contaminated oyster is to boil it until it is indigestible, when its powers for evil are not abolished, but only diverted into another channel.

Mark Twain on Eddyism.

MARK TWAIN, the inveterate humorist, takes a serious view of Eddyism. On the ground that four-fifths of the pain and disease in the world is purely imaginary, he assures us that Eddyism can get rid of it and that no other force can. He goes so far as to prophesy that in another quarter of a century Eddyism will have become the religion of the world, in which case medicine, as we understand it, will have become a lost art. Perhaps, however, this is only one of Mark Twain's "jokelets," for his antecedents do not justify his posing as a prophet and his knowledge of pain and disease is apparently limited to—Eddyism.

The Endowment of Medical Research.

THE announcement that Mr. John D. Rockefeller is about to devote £1,450,000 to the establishment and maintenance of a research hospital, where investigations will be directed mainly to means for preventing and curing consumption, has clearly indicated the true secret of the progress of our American cousins. While philanthropic and charitable institutions in this country still receive generous support, pure science and particularly experimental research into the problems of disease, is not only neglected but in many ways discouraged and by some actively opposed. We have studded the land with hospitals, while any back-shed has been considered good enough for a laboratory. We have spent lavishly in seeking to secure sanitary measures but we are still niggards in finding means for the study of prophylactic agents. Generous donors have found the wherewithal by which such institutions as the Mount Vernon Hospital for Consumption at Hampstead and Northwood may more adequately cope with the demands coming from all parts of England for efficient hygienic treatment. The proposed King's sanatorium it is hoped, will still further meet the necessities of many sufferers. But these and other institutions devoted to the treatment of consumption stand in urgent need of laboratories where the unsolved problems, which still envelop the disease in much perplexity, may be seriously and scientifically studied. We venture to think that in the past medical men have too much neglected to educate the lay mind into the necessity for research work if progress in practical application is to be

maintained. We hope to see a rapid development in this country of the ideas which are furnishing motive power to Americans, and placing trans-Atlantic workers in the van. If this can be accomplished the endowment of medical science will speedily follow.

Blood Photographs for Clinical Purposes.

EVERY clinical clerk knows what a tedious matter the estimation of the number of the red blood corpuscles may be. To facilitate this work and also to afford a convenient, useful and readily prepared permanent record, Dr. C. A. MacMunn advocates photographing the blood. The blood is diluted in a Thermo-Zeiss hæmocyclometer and spread on the graduated slide. The most suitable power is afforded by a $\frac{3}{4}$ -inch objective, and No. 4 Zeiss ocular, with 6-inch tube-length. A photograph is then taken, the microscope and camera being maintained in a vertical position. The method not only provides a permanent record, but enables the enumeration to be made at any time convenient to the investigator, and greatly lessens eye-strain, and diminishes the other only too well-known disadvantages of the commonly employed method of counting.

Public Parks as Sanatoria for the Consumptive.

THE facilities for effective combat with consumption are all too meagre, and the means for affording relief to the tuberculous poor are miserably inadequate. Many of our general hospitals close their doors to the phthisical, and most convalescent homes refuse to admit cases with pulmonary tuberculosis. The special hospitals and sanatoria for the poor are always full, and with lists filled with the names of scores of patients needing immediate admission. In most of the union infirmaries the accommodation for the phthisical is most unsuitable and many patients refuse to accept such as they give until compelled by advancing weakness and utter destitution. Until the State can be induced to provide suitable establishments for the consumptive poor, palliative and temporising measures must still continue, and according to long established custom we must muddle along. The poor imperil the rich, while the wealthy seek to shut their eyes to the sorrows of the sick pauper. The philanthropic few labour unceasingly, but the unheeding many pass on regardless of the danger all around them. Until the country awakens to the urgent needs of the situation it is well that ceaseless effort be made to enlighten mind and conscience. We venture to think therefore that on several grounds the suggestion to use the public parks of London and other great cities as sanatoria for the poor consumptive may be commended. It would no doubt place the peril dreaded by many prominently before the public, but this would be more reasonable than huddling the sick into crowded courts and alleys out of sight and so out of mind. If suitable shelters could be erected in well selected parts of many of our parks, and a well-trained attendant provided, much benefit would accrue to the afflicted ones. Now, in too many instances, the patient has to leave the sanatorium before

processes making for arrest have been established. In many instances the convalescent returns to the old non-hygienic environment, and after an ineffectual struggle to continue a more or less open-air treatment relapses into the old condition and joins the crowd of the hopeless. To such, opportunity for continuing during some hours of each day a modified sanatorium life in a large London park would be a boon, and in not a few instances a permanent benefit. We hope, at least as an experiment, shelters may be provided and reserved for the use of the consumptive in one or more of our parks, where during the day rest and fresh air and, we would add, suitable food and some measure of trained attendance might be provided.

Malaria Prevention at Ismailia.

THE prevention of malaria has now become, thanks to modern medical science, one of the great keys to the future colonisation of tropical countries. The subject has been ably dealt with as regards Ismailia by Major Ronald Ross in the January number of *Climate*. Ismailia has a population of about 7,000, yet in the years 1886, 1890, 1891, 1897, and 1901 nearly 2,500 cases were recorded. The town practically owes its existence to the sweet water canal, so that it is reassuring to learn that the canal is free from the larvæ of anopheles. Neither were the larvæ found in any of the irrigating branches, except in some small and shallow pools used for the cultivation of watercress. The reason for this exception appears to lie in the fact that small fish are not able to gain access to the larvæ in that situation. The conclusion of importance is that the waters which really occasion malaria are the most shallow and insignificant pools, which could be filled up or drained away without difficulty and without detriment either to cultivation or to irrigation. It was also noted that the larvæ both of anopheles and of culex are able to live in highly brackish but not in pure sea water. The preventive measures recommended are the general use of quinine, the segregation of Europeans from natives, the use of wire screens or nets to exclude mosquitoes from houses, and last, but not least, the extermination of mosquitoes. The problem of the prevention of malaria can be tested at a small place like Ismailia with every good prospect of arriving at a definite conclusion with regard to the probabilities of the case.

The Relative Functional Value of the Two Kidneys.

To the surgeon it is frequently of great importance that a diagnosis should be made of the relative condition of the two kidneys. Various physical methods and certain chemical investigations now place means for such discrimination at our disposal. Mr. Charles W. Cathcart, in the current issue of *The Scottish Medical and Surgical Journal*, furnishes a very convenient summary of the more important procedures, which should be of much service to those interested in renal surgery. He describes and discourses and discriminates such as the pyelo-vesical reflex, the uretero-vesical reflex, the cystoscopy, cryoscopy of the blood and urine,

the various artificial tests of the eliminatory power of the kidneys with methylene blue and phloridzin, the estimation of the excretion of urea and catheterisation of the ureters.

The Hinterland of Life.

THE realm of the invisible and the domain of the unknown have ever proved irresistible in their attractions for the speculative mind of man. Scientific men have been caught in the meshes of the net of fascination, and students, such as Mr. F. W. H. Myers, Professor W. James, Professor C. Richet, Sir William Crookes, Dr. A. R. Wallace, and Sir Oliver Lodge, have devoted much time and study to the problems of psychical research. The appearance of Mr. Frank Podmore's important work on "Modern Spiritualism" is likely to focus attention on what we may term "The Hinterland of Life." In these days when so-called "Christian Science" and "Mental Healing" are exercising the minds and attracting the practice of many thoughtful people it is well that medical men should lay aside that old medical manner which is based on dogma and upheld by an appeal to authority, and seek to guide, counsel, and correct those who in their not-to-be-denied excursions in psychical pastures are in danger of straying into pathological quagmires. In short, medical men must not dissociate themselves from the modern movement, which strives for a fuller investigation and better comprehension of "human faculty, human personality, and human destiny."

PERSONAL.

DR. S. INGLEBY ODDIE, Barrister-at-Law, has been appointed deputy-coroner for the Western Division of London.

MR. RALPH C. BARTLETT, M.R.C.S., L.R.C.P., has been appointed a Justice of the Peace for the borough of Romsey, Hants.

SIR GEORGE HARE PHILIPSON has been appointed Visitor on behalf of the General Medical Council of the final examinations of the University of Edinburgh for 1903.

DR. E. C. OSBORN, of Tooting, has been appointed medical officer to the Union Schools at Mitcham, on his return from upwards of two years' service with the forces in South Africa.

THE French Government have conferred the Cross of the Legion of Honour on Dr. Don Julio Robert, for his services to the French Colony in Madrid, for these many years past.

DR. EVERITT NORTON, Medical Superintendent of the Shoreditch Workhouse and Infirmary, has been presented by his Board of Guardians with a silver table service on the occasion of his marriage.

THE Hunterian Oration will be delivered by Mr. T. H. Openshaw, C.M.G., at the London Institution to-day (Wednesday), at 8.30 p.m., his subject being "John Hunter, his Influence on Surgery, with some Remarks on the Treatment of Appendicitis."

By a Royal decree under date of the 22nd of January

1903, Alphonsus the XIII. of Spain, has conferred the Grand Cross of the Civil Order of Alphonsus XII, on Dr. Don José Calvo-Martin, President of the Royal Academy of Medicine, and has nominated the Academician, Dr. Don Nicholas R. Abaytua, a Member of the Order.

THE Lord Mayor of London has kindly promised to give a dinner at the Mansion House on May 4th, in aid of the London Hospital special appeal now being made.

DR. A. S. GRUNBAUM, of Liverpool, has been appointed Director of Cancer Research by the Committee formed to administer the fund initiated by a gift of £10,000 by Mr. Sutton Timmis, of Liverpool. The investigations will be carried on in that city.

Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

THE CASE OF DR. RAINSBURY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—I am desired by the Council of the Midland Medical Union and by Dr. Rainsbury to acknowledge the receipt of further donations to the fund raised to assist Dr. Rainsbury in discharging the judgment which was given against him at the last Nottingham Assizes, and which was deemed to be a great hardship upon him. The judgment was for £25, and the costs were taxed at £152 6s. 2d., making together the sum of £177 6s. 2d. Of this, members of the profession have generously contributed £77 0s. 9d.

I have to express Dr. Rainsbury's gratitude to the contributors for their assistance and the thanks of the Council for the liberal response which has been given to the appeal. Will you kindly insert this letter in your next issue?

I am, Sir, yours truly,

GEORGE S. O'RORKE.
Secretary Midland Medical Union,
Nottingham.

February, 9th 1903.

ASYLUM FIRES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The terrible catastrophe at Colney Hatch will, I imagine, come as an "eye opener," to use a colloquial phrase. If some evil genius had set to work to devise a structure which should take fire on the slightest provocation—and in a building filled with lunatics such provocation is likely to occur—he could not possibly have put together one which would burn with more certainty and rapidity. Not a factor was omitted—inflammable matchboard walls and floors, tarred felt behind to assist in furnishing the requisite combustible, connecting passages along which the fire might first creep and then rush, locked doors, the keys whereof were not to be found at the critical moment—really it is difficult to conceive of any further element of danger that could have been introduced except, perhaps, giving matches to the patients to play with, and we have no proof that there were none on the premises.

The circumstances are aggravated by the fact that there are such things as "sprinklers," a mechanical and not very costly appliance for the automatic extinction of fires—worth having for the purpose of saving

a few bales of cotton from destruction, but too costly for the mere saving of life. Then, too, we have heard a good deal of fire-proof paints, some of which, at any rate, have given remarkable results in actual experiments. There are "extincteurs," and hand grenades, not altogether trustworthy appliances, perhaps, should the fire already have obtained a good hold, but still much better than screams on the one hand, and heroism on the other.

It is heart-rending when one thinks of what might have been done and of the utter absence of anything that was done in the direction of fire preventives. It is to be hoped that the jury will not allow a dead architect to be made the scapegoat for these hideous shortcomings, but will nail the responsibility to some living person or persons.

This, after all, is but a beginning. Unless strong measures are taken further catastrophes of the same kind are inevitable and I can but throw my mite into the balance in the hope of stimulating public opinion on the subject.

I am, Sir, yours truly,
ONCE AN INMATE.

Literary Notes and Gossip.

SIR ARTHUR CONAN DOYLE'S works are to be issued in a uniform edition by Messrs. Smith, Elder and Co.

MEDICAL officers connected with prisons and particularly those who are, or have been, in charge at Parkhurst, will be interested in the chapter in the recently issued remarkable autobiography, *Penal Servitude*, which portrays certain members of the profession in an interesting light.

MR. GEORGE GISSING in "The Private Papers of Henry Ryecroft," just published, expresses the wish to add a new petition to the Litany. Many a doctor could find it in his heart to furnish the *Amen*. "For all inhabitants of great towns, and especially for all such as dwell in lodgings, boarding-houses, flats, or any other sordid substitute for home which need or foolishness may have contrived."

THE fascinating "Life of Robert Buchanan," by Miss Harriet Jay, recently issued by Mr. T. Fisher Unwin, contains much that is of peculiar interest to the medical mind, particularly the close and personal study of the mental attitude of the consumptive afforded in the chapter devoted to Buchanan's friend—David Gray—the young poet who died in the twenty-fourth year of his age from pulmonary tuberculosis.

HIS Majesty the King and his Royal Highness the Prince of Wales have graciously been pleased to accept a copy of the King's Prize Essay for the Erection of "The King Edward VII. Sanatorium" for the Treatment of Tuberculosis, by Arthur Latham, M.A., M.D.-Oxon., M.A. Cantab., Assistant Physician at St. George's Hospital, and at the Brompton Hospital for Consumption, in association with A. William West, Architect. (London: Bailliere, Tindall and Cox.)

OLIVER WENDELL HOLMES still lives in the affections of medical men on both sides of the Atlantic, and the electric brilliancy of his works still stimulates the mind and strengthens the spirit of many a jaded practitioner. In times of weariness and moments of discouragement the words of "the Autocrat," or the advice of "the Professor" lightens the burden and heartens the life. A course of Dr. Holmes is often the best "tonic" a medical man can secure for his own spirit's strengthening. To all lovers of this "well-beloved physician" we commend the charming volume *Boston Days*, by Lilian Whiting, which contains much of highest interest concerning Oliver Wendell Holmes.

Literature.

PHARMACOLOGICAL STUDIES AND THE USE OF NITRITES. (a)

THIS little work is one of much pathetic interest. It contains the Croonian Lectures and other essays on pharmacological subjects of the late Professor Leech, whose untimely death in 1900 prevented the coming out of several important literary projects for which he had collected much material. Professor Wild, his successor in the Chair of *Materia Medica* and Therapeutics at Manchester, has done well to collect into one volume the various papers of his friend and master; and the book will be valued by many of Professor Leech's old students. The first portion of the volume contains reprints of several interesting essays, the most important being an address on the relation of pharmacology to therapeutics, delivered as far back as 1884. No alteration has been made in the text of the earlier papers. The Croonian Lectures on the pharmacological action and therapeutic uses of the nitrites and allied compounds, which appeared in the medical journals of 1893, and constitute the most valuable portion of the present volume, have been revised, divided into chapters, and additional figures have been added. Dr. Wild tells us, however, that the present work represents the views held by Professor Leech in 1900, when he contributed the article upon the nitrite group to Dr. Hale White's well-known text-book; before writing that article he revised a copy of the Croonian Lectures, and use has been made of this in preparing this book. Valuable as such a permanent record of the more important researches of the late Dr. Leech will be to pharmacologists, and prized as it must be by all those who were privileged to have come in contact with him, the present volume will probably prove of great service to the serious student from the very excellent and complete bibliography of the nitrites, which occupies no less than twenty-two pages. The well-executed series of plates add much to the usefulness of the work.

BIGG ON CONSTIPATION (b).

In his introduction the author says that "constipation is one of the weak spots in the defence of the constitution." So it is, and this small volume not only directs attention to its dangers, but also tells us how to deal with them. The author first points out the various evils that result from constipation, and then carefully considers its diagnosis and treatment. He divides his subject into three parts, simple, habitual and chronic constipation. A number of useful and practical prescriptions are appended to the volume. The general practitioner will find many valuable hints within this book, and we can confidently recommend it as a thoroughly practical contribution to the literature of this oft-neglected condition.

WHITLA'S MATERIA MEDICA. (c)

THIS manual is now so well known and so widely used by students and practitioners that very little new can be said regarding it. In its present form, however, it differs from previous editions in that the size of page is larger and also the type. Much of it

(a) "The Pharmacological Action and Therapeutic Uses of the Nitrites and Allied Compounds, including the Croonian Lectures for 1893." By the late Daniel John Leech, M.D., D.Sc., F.R.C.P., Professor of *Materia Medica* and Therapeutics in the Owens College. Edited by R. B. Wild, M.D., M.Sc., M.R.C.P., Leech Professor of *Materia Medica* and Therapeutics in the Owens College. Pp. 187, and XXVIII plates. Manchester: Sherratt and Hughes, 1902.

(b) "Constipation." By G. Sherman Bigg, F.R.C.S. Pp. 76. Crown 8vo. Price 2s. 6d. net. London: Baillière, Tindall, and Cox, 1902.

(c) "Elements of Pharmacy, *Materia Medica*, and Therapeutics." By William Whitla, M.A., M.D., Professor of *Materia Medica* and Therapeutics in Queen's College, Belfast, etc. Eighth Edition. Pp. 637. London: Henry Renshaw, 1903.

has been re-written, and the whole brought well up to date. The section on pharmacy is exceedingly well arranged, and is brimful of valuable hints; while that on *materia medica*, which, by the way, is got up in alphabetic form, is at once clear and concise. We were perhaps most interested in that part which treats of therapeutics, where brevity and accuracy go hand in hand. To prove the fact that the book is brought up-to-date we turned to the section on potassium iodide, and were not disappointed, for there we found reference made to Professor Stockman's recent researches on the subject. The section on non-official remedies is wonderfully complete, no remedy of any consequence being omitted. As a text-book for students, or as a work of reference for the general practitioner, this volume, in its new and improved form, will be found all that can be desired.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list.

BAILLIÈRE, TINDALL & COX (London and Dublin).

The King's Prize Essay on the Erection of a Sanatorium for the Treatment of Tuberculosis in England. By Arthur Latham, M.A., M.D., Oxon., M.A. Cantab., in association with A. William West, Architect. Pp. 254. Price 5s. net.

The Diagnosis and Modern Treatment of Pulmonary Consumption. By Arthur Latham, M.A., M.D. Pp. 215. Price 5s. net.

Aids to Sanitary Science. By Francis J. Allen, M.D. Edin. Second Edition, revised and edited by Reginald A. Farrar, M.A., M.D., Oxon. Pp. 272. Cloth 4s. 6d., paper 4s.

The Practical Details of Cataract Extraction. By H. Herbert, F.R.C.S. Pp. 109. Price 4s. net.

JOHN BALE, SONS & DANIELSON, LTD. (London).

The Surgical Treatment of Ulcer of the Stomach. By C. Mansell Moullin, M.D., Oxon., F.R.C.S. Pp. 53. Price 2s. 6d. net.

CASSELL & Co., LTD. (London).

Diseases of Women. By George Ernest Hermann, M.B., Lond., F.R.C.P. With upwards of 250 Illustrations. Pp. 884. Price 25s.

HENRY FROWDE (London).

The Hospital Service Book. Revised and Enlarged. By Charles Parkhurst Baxter, M.A. Pp. 218. Price 2s.

GOVERNMENT PRINTING OFFICE (Washington, U.S.A.).—Index-Catalogue of the library of the Surgeon-General's office, United States Army. Second Series, vol. VII. Hernia—Inquiry. Pp. 1,003.

JORDAN & SONS, LTD. (London).

A Practical Guide to the Licensing Act, 1902. By Charles L. Rothera, B.A. Pp. 157. Price 3s. 6d. net.

H. K. LEWIS (London).

Diseases of the Skin. By H. Radcliffe Crocker, M.D., Lond., F.R.C.P. Third Edition, 2 vols. Pp. 1,387. Price 28s. net.

Inoculation against Malaria. By Dr. Philaethes Kuhl. Translated by H. A. Nesbitt, M.A. Pp. 32. Price 2s. net.

J. B. LIPPINCOTT & Co. (London).

International Clinics. Edited by Henry W. Cattell, A.M., M.D. Vol. IV., Twelfth Series, 1903. Pp. 317.

LONGMANS, GREEN & Co. (London).

Memoirs and Letters of Sir James Paget. Edited by Stephen Paget, one of his sons, with a Portrait. Third Edition (eighth impression), with a Postscript by Sir Thomas Smith. Pp. 466. Price 6s. net.

The Mycology of the Mouth. By Kenneth Weldon Goadby, D.P.H. Camb., L.R.C.P., &c. Illustrated. Pp. 241. Price 8s. 6d. net.

Bacteria in Daily Life. By Mrs. Percy Frankland. Pp. 216. Price 5s. net.

MACMILLAN & Co., LTD. (London).

Life History Album. Second Edition, re-arranged by Francis Galton, D.C.L., F.R.S. Pp. 178. Price 5s. net.

YOUNG J. PENTLAND (Edinburgh and London).

The Edinburgh Medical Journal. Edited by G. A. Gibson, M.D., F.R.C.P. Edin., and Alexis Thomson, M.D., F.R.C.S. Edin. New series, vol. XII. Pp. 592.

REBMAN, LTD. (London).

Biographic Clinics: The Origin of the Ill-health of De Quincey, Carlyle, Darwin, Huxley, and Browning. By George M. Gould, M.D. Pp. 223. Price 5s. net.

HENRY RENSHAW (London).

Elements of Pharmacy, *Materia Medica*, and Therapeutics. By William Whitla, M.A., M.D. With woodcuts, Eighth Edition Pp. 637.

ELLIOT STOCK (London).

What a piece of Work is Man; with Christian Evidences. By Frederick James Gant, F.R.C.S. Price 2s. 6d. Pp. 105.

JOHN WRIGHT & Co. (Bristol).

Golden Rules of Refraction. By Ernest E. Maddox, M.D., F.R.C.S. Edin. Pp. 86.

Medical News.

Royal College of Surgeons of England Lectures.

THE following lecture arrangements are announced:—Professor Charles B. Ball, Erasmus Wilson Lecturer, will deliver three lectures on "Adenoma and Adeno-Carcinoma of the Rectum," February 16th, 18th, and 20th. Mr. J. Herbert Parsons, Arris and Gale Lecturer: three lectures on "Ocular Circulation," February 23rd, 25th, and 27th. Professor Arthur Keith, three lectures on "A Research into the Manner in which the Abdominal Viscera are Maintained in Position in Man and in Animals Allied to Man with a view of Elucidating the Condition usually described as 'Glenard's Disease,'" March 2nd, 4th, and 6th. Professor W. McAdam Eccles, three lectures on "The Vermiform Appendix; some points in its Anatomy and Pathology," March 9th, 11th, and 13th. All members of the profession will be admitted to these lectures on presenting their private visiting cards.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Committee of the Medical Sickness, Annuity and Life Assurance Society was held on January 30th, at 429, Strand, W.C. There were present, the chairman, Dr. de Havilland Hall, Dr. G. A. Hiron (one of the trustees), Dr. J. B. Ball, Dr. Frederick S. Palmer, Dr. Walter Smith, Dr. M. Greenwood, Dr. F. J. Allan, Dr. W. Knowsley Sibley, Dr. Alfred S. Gubb, and Mr. Edward Bartlett. The amounts presented showed that a large number of claims were being received on account of influenza, and there seems little doubt that an epidemic of this disease has to be reckoned with. In previous years considerable sums have been paid by the Society on account of influenza claims, but the large reserve, which now amounts to more than £17,000 has never ceased to grow, and the present claims though numerous, are of short duration, and are easily met out of current income. A long list of members who, being permanently incapacitated, are drawing annuities, usually one hundred guineas a year, was examined, and the special report furnished gave little hope of any appreciable reduction in this list. To make these annuities absolutely secure a special reserve is made at each valuation of the Society's business. Prospectuses and all information on application to Mr. F. Addiscott, Secretary Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

The First to be Chloroformed.

THE death is announced of Dr. John Webb Watkins, of Newton-le-Willows, Lancashire, who is stated to have been the first human being on whom the anaesthetic effects of chloroform were tried by the late Sir James Y. Simpson.

Vital Statistics.

THE deaths registered last week in the eighty great towns of the United Kingdom corresponded to an annual rate of 19 per 1,000 of their aggregate population. The highest annual death rates per 1,000 living, as measured by last week's mortality, were:—From all causes, 26 in Belfast, 24 in Dublin, 22.7 in Glasgow, 17.8 in Edinburgh, 23.1 in Hanley, 23.3 in South, Shields, 23.5 in West Bromwich, 23.7 in Norwich, 24.0 in Oldham, 24.6 in Rotherham, 25.1 in Newcastle-on-Tyne, and 26.0 in Wigan; from measles, 1.2 in Manchester, 1.3 in Hull, 1.5 in Belfast, 3.7 in Newport (Mon.); and from whooping-cough, 1.2 in Bristol, 1.5 in Oldham, 1.7 in Northampton, 1.8 in Smethwick, 1.9 in Tottenham, 2.2 in Stockport, 2.5 in Hanley and in King's Norton, and 3.3 in Croydon. Six deaths from small-pox were registered in Liverpool, three in Leicester, and one each in Walsall, Birmingham, Bury, and Manchester, but not one in any other of the eighty towns.

Mortality of Indian and Foreign Cities.

THE following is the official weekly return of the

rates of mortality in certain Indian and foreign cities, which gives the annual death rate per 1000 living in Bombay at 56.6, Paris 20.0, Brussels 18.0, Antwerp 13.7, Amsterdam 14.3, Copenhagen 17.1, Stockholm 14.3, Christiania 26.4, St. Petersburg 23.5, Moscow 25.6, Hamburg 18.8, Munich 22.6, Vienna 19.2, Buda-Pesth 18.2, Trieste 28.6, Rome 21.2, Cairo 28.6, Alexandria 35.8, New York 18.5, 20.0, Philadelphia 22.2, Boston 20.5.

The Dublin Death-rate.

THE deaths registered in the Dublin registration area for the quarter ending Saturday, January 3rd, 1903, represent an annual rate of mortality of 28.7 in every 1,000 of the population, being an increase of 1.4 in every 1,000 on the mortality of the corresponding quarter of the past ten years. Tuberculous diseases caused 454 deaths; diseases of the nervous system caused 270; diseases of the circulatory system caused 328; and diseases of the respiratory system caused 640. Influenza proved fatal in 27 instances. Forty-one deaths are ascribed to typhoid fever, and five from typhus. The recent epidemic of measles accounts for 177 deaths, as against 0, 23, 39 and 153 respectively in the four preceding quarters. The last weekly return to hand gave an annual death-rate of 25.7 per 1,000.

The London University and the Classics.

AT the quarterly meeting of the Apothecaries' Hall of Ireland held last week, it was moved by J. C. M'Walter M.A., D.P.H., seconded by E. F. Hanrahan, M.B., and carried unanimously. "That the Governor and Company of Apothecaries' Hall observe with grave concern that a knowledge of Latin is no longer essential to candidates for the London University Matriculation Examination, and they request their representative on the General Medical Council to insure that no person shall be registered as a medical student who shall not have passed in that subject."

The Royal University of Dublin.

AT the meeting of the Senate on Friday, February 6th, the following appointments were made:—Medical Fellows—Ambrose, Birmingham, M.D., Joseph P. Pye, M.D., Johnson Symington, M.D., John J. Charles, M.D., D. J. Coffey, M.B., John I. Lynham, M.D., John S. McArdle, F.R.C.S.I., Charles Y. Pearson, M.D. Examiners:—In Medicine—James A. Lindsay, M.D., Joseph J. O'Carroll, M.D. In Pathology—Edmond J. McWeeney, M.D., J. Lorrain Smith, M.D. In Midwifery—John W. Byers, M.D., Alfred J. Smith, M.B. In Medical Jurisprudence and Sanitary Science—Anthony Roche, M.R.C.P.I., Patrick T. O'Sullivan, M.D. In Materia Medica—Martin Dempsey, M.D., Sir William Whitla, M.D. In Ophthalmic Surgery—Arthur W. Sandford, M.D., Louis Werner, M.B. In Physiology—T. H. Milroy, M.D. In Sanitary Science—Sir Charles A. Cameron, C.B., M.D., In Mental Diseases—Conolly Norman, F.R.C.P.I., George Rivington, M.D. Extern Examiners:—In Surgery—Charles Stonham, F.R.C.S.E., In Midwifery—Henry Jellett, M.D. In Pathology—A. C. O'Sullivan, M.D. In Ophthalmology—William G. Sym, M.D.

PASS LIST.

Trinity College, Dublin. Hilary Term. 1903.

PREVIOUS MEDICAL EXAMINATION.

Anatomy and Institutes of Medicine.—Robert A. Askins, Cecil Scaife, John B. B. Whelan.

Physics and Chemistry.—Henry H. A. Emerson, Joseph C. A. Ridgway, Joseph E. N. Ryan, William E. M. Armstrong, Cyril H. M'Comas, John Murdoch.

Botany and Zoology.—Thomas P. Dowley, William M. Johnston, William H. Kennedy, Charles F. Rolleston, James G. M. Moloney.

Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

DR. J. P. H.—From personal knowledge we should advise Grasse, in the French Riviera, for your patient. At the principal hotel there (the Grand Hotel) he would find every possible comfort in convalescence. Both air and water are pure, and there is not the excitement which obtains at the more popular resorts.

MEDICAL MEN IN WALES.

Wales possesses 1,186 medical men, most of whom derived their training from schools outside the limits of the Principality. Of these 480 received the chief part of their medical education in London, 412 in Scotch, and 130 in Irish medical schools. The remainder have studied in English provincial colleges and universities. These numbers are only approximately accurate, as many medical men have availed themselves of the freedom permitted them, and taken parts of their courses in different colleges and universities.

NORTHERN SUBURB.—A parallel case is mentioned in Sir William Broadbent's manual on "Heart Disease" (3rd edition). Therein you will find the most suitable treatment, pursued with the best results.

DR. N. Y., M.D.—Received and will be considered.

M. B. GRIMSHAW.—Your request has been forwarded to the writer.

A. G. B.—We thank you for calling attention to the statements in our last issue. It was certainly not the intention of the writer to condemn the use of the convenient bath apparatus made for the purpose of rapidly heating water. We regret that the paragraph in question should have been open to any such interpretation. In the unfortunate accident that formed the subject of our comment, the cause of death was obviously the use of a gas stove. The main fact remains that the absence of ventilation in the bath-room was the indirect cause of death, and it is to be hoped that the loss of a valuable life may lead to a wide recognition of the disaster that may attend a similar carelessness of construction elsewhere.

DR. ALFRED F. PENNY.—Your paper on "Oral Sepsis as a Factor in the Causation of Disease" is marked for early insertion.

DR. J. B. R. (Harlesden) will receive a private note.

OXONIENSIS.—The hospital in question is one of the best equipped in the provinces. The operating theatre will stand comparison with that of any other institution of its class with which we are acquainted. From a scientific point of view the teaching to be gained thereat is, beyond doubt, sound, comprehensive, and satisfactory. A similar commendation, however, can hardly be extended to its possibilities in a clinical direction. The number of patients is too small to afford the field necessary for a thorough and comprehensive practical medical education.

MR. J. B. T. is thanked, but his communication is unsuitable.

MERC.—The plant is not officially recognised in this country, and its reputation, so far as we can judge, reposes solely on the publicity given to it by certain enterprising pharmacists.

Meetings of the Societies, Lectures, &c

LONDON.

WEDNESDAY, FEBRUARY 11TH.

SOUTH-WEST LONDON MEDICAL SOCIETY (Bolingbroke Hospital, Wandsworth Common).—8.45 p.m. Paper:—Mr. W. E. Miles: The Diagnosis and Treatment of Certain Common Affections of the Rectum met with in General Practice.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. J. Clarke: Clinique. (Surgical.) 5.15 p.m. Dr. C. O. Hawthorne: The Visual Field in Chronic Nervous Disease. I.

THURSDAY, FEBRUARY 12TH.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Macnaughton-Jones and others. Dr. H. Smith (President): Introductory Address.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. J. Hutchinson, Jun.: Clinique. (Surgical.) 5.15 p.m. Dr. C. O. Hawthorne: The Visual Field in Chronic Nervous Disease. II.

FRIDAY, FEBRUARY 13TH.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi Terrace Strand, W.C.).—7.30 p.m. Dr. E. W. Hope: The Renewal of the Vaccination Act.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Papers:—Mr. H. L. Barnard: Treatment of Suppurative Arthritis. Dr. S. Barnes (introduced by Sir William Gowers): A Case of Local Panatroph. Mr. A. A. Bowly, C.M.G.: A Case of Acute Pancreatitis. Dr. F. Taylor: A Case of Acute Pancreatitis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. R. Lake: Clinique (Throat.) 5.15 p.m. Dr. H. Lilley: Purulent Nasal Discharges. II.

MONDAY, FEBRUARY 16TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, 5 p.m. Prof. Charles C. Ball: Adenoma and Adeno-Carcinoma of the Rectum.

DUBLIN.

ROYAL ACADEMY OF MEDICINE, DUBLIN.—Feb. 13th.—Section of Obstetrics. Papers:—Dr. Purefoy: Report of the Rotunda Hospital for the year 1901—02. Dr. W. Cockle: A Case of Puerperal Eclampsia, with Post-mortem Delivery by Forceps Exhibits by Card:—Dr. E. H. Tweedy: Three Myomatous Uteri Removed by Abdominal Hysterectomy. Dr. Alfred Smith: 1.—Five Myomatous Uteri. 2.—Double Pyosalpinx (Tubercular). 3.—Double Pyosalpinx (Septic). Dr. Horne: Ovarian Cyst. Specimens:—Dr. Alfred Smith: Ectopic Gestation.

Vacancies.

Borough of Torquay.—Medical Officer of Health. Salary £400 per annum. Applications to Fredk. S. Hex, Town Clerk, Town Hall, Torquay.

Bradford Royal Infirmary.—Dispensary Surgeon. Salary £100 per annum, with board and residence. Applications to William Maw, Secretary.

County Asylum, Whittingham, Preston, Lancashire.—Assistant Medical Officer. Salary £150, with furnished apartments, board, washing, and attendance provided. Applications to the Medical Superintendent.

County Asylum, Prestwich, Manchester.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Applications to Medical Superintendent.

General Hospital, Birmingham.—Resident Pathologist. Salary £100 per annum, with board and residence. Applications to the House Governor.

Kent County Asylum, Barming Heath, Maidstone.—Fourth Assistant Medical Officer. Salary £175 per annum, with furnished quarters, attendance, coal, gas, garden produce, milk, and washing. Applications to F. Pritchard Davies, M.D., Superintendent.

Lanark District Asylum, Hartwood.—Third Assistant Medical Officer and Pathologist. Salary £120 per annum, with fees, board, washing, and residence. For full particulars apply to the Medical Superintendent (see advt.).

Metropolitan Hospital.—Casualty Officer. Salary £150 per annum. Applications to Charles H. Byers, Secretary.

Newcastle-on-Tyne Dispensary.—Two Visiting Medical Assistants. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 41, Mosley Street, Newcastle-on-Tyne.

North Riding Lunatic Asylum, Clifton, York.—Senior Assistant Medical Officer. Salary £200. Applications to the Medical Superintendent.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing. Applications to E. S. Baylis, J.P., 19, Moorgate Street, Rotherham.

Royal National Hospital for Consumption and Diseases of the Chest, Ventnor.—Assistant Resident Medical Officer. Salary £100 per annum, with board and lodging in the Hospital. Applications to the Secretary, 34, Craven Street, Charing Cross.

West Derby Union.—Senior Medical Officer (Resident), for the Workhouse and Hospital, Walton, Liverpool. Salary £150 per annum, with board and apartments, and fees for vaccination. Applications to Harris P. Cleaver, Clerk to the Guardians, Union Offices, Brougham Terrace, Liverpool.

White Oak Ophthalmia School, Swanley, Kent.—Assistant Medical Officer. Salary £150 per annum, with £100 per annum in lieu of Residential Allowances. Applications at Office of the Board, Embankment, E.C.

Appointments.

EGLINTON, GEORGE WALTER, L.R.C.P., L.M. Edin., L.F.P.S. Glas., Medical Officer of Health for the Wells (Somerset) Rural District Council.

HUTCHINSON, HY, L.R.C.P., L.R.P.S. Glasg., L.S.A. Lond., Surgeon to the London and India Docks Employees of the Districts of East Ham, Upton, and Manor Park.

LITLER-JONES, T. C. F.R.C.S. Eng. Honorary Assistant Surgeon to the Liverpool Royal Infirmary.

LYNCH, M. E., L.R.C.P.I., L.R.C.S.I., Medical Officer for Clashmore co. Waterford, Dispensary District.

McMORDIE, D. M.B., C.Ch.R.U.I., House Physician to the Sheffield Royal Hospital.

MARSHALL, R. PRYNNE, M.B.C.S. Eng., L.R.C.P. Lond., Medical Officer to the Third District of the St. Olave's Union, and Certifying Surgeon to the Bermondsey Borough Council.

MONCKTON, WILLIAM, L.R.C.P., L.M. Edin., M.R.C.S., Medical Officer of Health for the Portishead Urban District Council.

SCHOFIELD, F. W., M.B., C.Ch. Vict., Assistant House Surgeon to the Sheffield Royal Hospital.

SHAW, G. H., M.B., Ch.B. Vict., House Surgeon to the Sheffield Royal Hospital.

WALLACE, ARTHUR J., M.D. Edin., Surgeon to the Hospital for Women, Liverpool.

Marriages.

PRIDIE—KESTON.—On Feb. 5th, at the Cathedral, Peterborough, Hugh Hampden Pridie, M.B., Wandsworth, Northamptonshire, to Eva Hester, only daughter of Haydn Keston, Mus. D. Oxon., Organist of Peterborough Cathedral.

Deaths.

HEARNDEN.—On Feb. 5th, at Sutton, Surrey, William Alexander Hearnden, M.D., aged 70 years.

The Medical Press and Circular.

ON THE CURATIVE TREATMENT OF TRACHOMA

BY
X-RAY TUBE EXPOSURE
AND BY
HIGH FREQUENCY CURRENT.

By SYDNEY STEPHENSON, C.M.,

Hon. Secretary of the Ophthalmological Society,

AND

DAVID WALSH, M.D., Edin.,

Late Hon. Secretary of the Rontgen Society, London.

It is a familiar observation that the number of remedies advocated in any given disease affords a good test of its obstinacy, or otherwise, under treatment. The proposition is certainly true when applied to the extremely chronic contagious disease of the conjunctiva known as "granular lids" or "trachoma." A well-nigh bewildering list of local measures, instrumental and escharotic, has been compiled on the authority of generations of ophthalmic surgeons in their battle against the formidable malady in question. Without entering into detail it may be briefly stated that in spite of this crowded armoury, modern methods, even in the most experienced hands, rarely succeed in curing the disease within one or two years. The results, for instance, in a large number of cases of trachoma treated at the Hanwell Ophthalmic Schools show that the average period of cure reached two years. It should be borne in mind, moreover, that these figures were obtained under conditions of a most favourable kind as regards skilled nursing, the regular application of remedies, the performance of operations, and a bright and wholesome environment. There is little need to labour the point, however, for every surgeon attached to the ophthalmic out-patient department of a hospital will recall cases of trachoma that remain uncured after years of more or less continuous attendance. Clearly, then, the malady must be regarded as lingering and obstinate under all forms of treatment hitherto devised.

On the whole it seems that surgical measures have so far afforded the best results, inasmuch as they materially shorten the course of the disease, and in that way prevent the likelihood of such troublesome and serious complications as pannus, ulcers of the cornea, and trichiasis. Practical surgeons have therefore learned to trust more and

more to surgical measures in dealing with trachoma. That position, however, seems likely to be entirely changed by the introduction of two powerful remedial agencies, to wit, the X-ray focus-tube and the "high frequency" electrical current. The first-mentioned method is commonly called X-ray treatment, but inasmuch as it is not yet known whether the X-rays are themselves the sole, or even the chief therapeutic agents, we think it better to adopt a non-committal phrase by adding the words "focus-tube." (a)

The only recorded instance of the use of the X-ray tube in trachoma is the single case of a girl, æt. 14, whose left eye was treated by Mr. M. S. Mayon. The patient was shown on June 12th, 1902, before the Ophthalmological Society of the United Kingdom. (b) Her left eye had been exposed on 22 occasions to the focus-tube and was nearly, but not quite, cured. A search among contemporary literature has failed to disclose any further account of the use of the X-ray methods in trachoma, nor has any mention whatever been found of the application of the high frequency current to the treatment of that disorder.

The focus-tube treatment has been applied by us with varying results in several forms of eye disease. In the present communication, however, it is proposed to deal with trachoma alone. Four cases have been thus treated, and in all of them a marked improvement was at once noted. The four patients were male children, whose ages ranged from two to twelve years. In each of them both eyes were affected with typical hypertrophic and severe trachoma, the cornea being involved in three cases. Under ordinary treatment one might have expected to cure these cases, say, in the course of eighteen months or two years.

Little need be said about the actual details of treatment. A twelve-inch Cox's coil was used with the "Record" focus-tube of the same maker. For the first few exposures the apparatus was run with a strong battery and an ordinary spring break. Afterwards a Mackenzie-Davidson mercury break (of the improved form made by Cox) was substituted, together with current run direct from the main. The focus-tube was "hard," with an average resistance equal to a seven or eight-inch spark gap on the coil. The anticathode of the focus-tube was placed at an average distance of eight inches from the eye, and the average exposure was from ten to fifteen minutes. One child proved more susceptible to the action of

(a) See "Rontgen Rays in Medical Work." By D. Walsh, M.D. Third Edition, pp. 201

(b) "Transactions of the Ophthalmological Society," vol. xxi. (1902).

the focus-tube than the others. After the first few exposures a mask of lead foil was used to protect the face, and so made that one or both eyes could be exposed to the tube. An average current strength of five amperes and twenty to twenty-five volts was used. In order to control results, one eye only was exposed in three out of the four cases, and in one of the three (Case II.) the lids were held everted during exposure. In the fourth (Case I., trachoma and pannus) both eyes were exposed simultaneously to the focus-tube, and the lids of the right eye were everted. The cases were chosen from children in whom the disease was well marked and bilateral and as nearly as possible of equal severity on the two sides.

The general results may be thus stated: Of the four cases of trachoma treated with the focus-tube the eyes appeared to be cured in two (Cases II. and III.), while such considerable improvement took place in the other cases as to promise an equally favourable result with a continuance of the treatment. On several occasions slight superficial dermatitis of the lids was noted, and in one case it amounted to a blister. The face was also similarly affected once or twice. A moderate dermatitis also occurred on the fingers and back of hand of the nurse who held the lids everted during one of the short distance exposures (four inches). A shield and a mask of lead prevented any further mischief, so far as hands and face were concerned.

The rapidity of the curative action is noteworthy. Every case showed a definite improvement from the first exposure. The immediate effect of the focus-tube was to render the granular bodies redder and more prominent. That appearance was followed by a stage during which rapid absorption of the granulations presumably took place. Out of the five eyes treated in the four patients two appear to be cured at the time of writing, while the rest of the treated eyes are well on the road to cure. On the other hand, the three eyes untreated by the focus-tube remain just as they were when the patients were first put under this special treatment, that is to say, the conjunctiva shows at the present moment severe typical trachoma. During the focus-tube exposures the eyes not thus exposed have been treated daily with an ordinary antiseptic wash. The method of control adopted establishes the fact that the curative agency has been exposure to the focus-tube, as that has been the only altered condition preceding cure or marked improvement in the treated eyes. The eversion or otherwise of the lids appears not to make the least difference in results. This is fortunate, as it is no light task for the operator or his assistant to keep a child's lids everted for ten minutes or a quarter of an hour at a time. The apparent cure of the two eyes resulted from seventeen exposures in Case II., and from sixteen in Case III. It may safely be claimed that these results obtainable by a few weeks' treatment with the focus-tube opens up a new era for the ophthalmic surgeon, not only as regards trachoma, but other diseases of the eye as well. The clearing up of the corneal opacities and the partial disappearance of the pannus in Case IV., suggest an extended and important application of the Röntgen methods in ophthalmic work.

With regard to the trachoma apparently cured by the high frequency current, the results were obtained after twenty-two applications. A twelve-inch spark coil (Cox) was run from the main con-

nected with a D'Arsenval high frequency apparatus. One end of the solenoid was earthed, while the other was connected with a vulcanite electrode, with which the closed right eyelids were gently massaged. A small brush discharge of about half an inch was obtainable from the electrode, and this probably would have acted on the trachoma equally well without actual contact of the electrode with the lids. It was noted that at times the orbicularis and the corrugator supercilii muscles were thrown into action. So far as we can ascertain this is the first application of the high frequency current to the eye. Its results have been not less striking than definite. By this means, as with the focus-tube, more improvement has been effected in trachomatous lids than could have been reasonably expected under months or even years of ordinary escharotics.

Treatment both by the focus-tube and by high frequency current has the great merit of painlessness. Under both methods it was a common occurrence for the children to fall asleep. This state of things offers a sharp contrast to the discomfort and pain produced by the application of solid sulphate of copper and other escharotics—liquid or solid—to the conjunctiva, suffering that is only partially checked by cocaine. The rapidity of cure is another important fact, as it not only prevents a needless expenditure of time and money, but it also reduces the chances of onset of serious complications that beset the path of trachoma, especially as regards the cornea. As all ophthalmic surgeons know, the longer the course of the disease the greater the risk of complications. Almost, if not quite absolute safety may be claimed for both forms of treatment if applied by skilled hands. At the same time it can be hardly too strongly insisted upon that the application of the focus-tube to the eye by unskilled or careless persons might play havoc with a delicate organ.

In addition to the slight surface "burns" above noted, the eyelashes became thinner in some of the eyes treated by the focus-tube. In Case I., after ten exposures with everted lids, a small infiltration appeared in the lower fourth of the cornea, looking like an ordinary phlyctenular (eczematous) deposit. This was followed in the course of the next week by several similar but smaller deposits in the lower outer quadrant of the cornea, and these later developed into small ulcers. It is an open question whether these phenomena were or were not connected with the special treatment.

The results thus obtained open up a new and brilliant field in the treatment of a disease that inflicts many disabilities upon the poorer classes of the United Kingdom. Among the Poor-law institutions the prevention of trachoma has long been a most urgent and difficult problem. The prevalence of the malady, indeed, has been perhaps one of the strongest arguments brought forward against the massing together of many children in the so-called "barrack schools." It almost seems that the means of rooting out the disease from the Poor-law institutions has been placed in the hands of the medical profession. If that be the case, it is within the bounds of possibility that granular lids may be banished from our Poor-law population within a few months of the general application of the electrical methods described in the present article. So far as can be seen at present, in skilled hands both the focus-tube and the high frequency current will substitute

safety, rapidity and efficiency for methods that have hitherto necessarily been slow, painful, uncertain and costly. Should such a result as we anticipate be possible under the new methods the consequent saving of money both to local authorities and to the State, to say nothing of the benefit to the individual, would be simply incalculable.

ABSTRACT OF FOUR CASES OF TRACHOMA TREATED BY THE FOCUS-TUBE, AND ONE WITH THE HIGH FREQUENCY CURRENT.

CASE I.—C. H., æt. 9. Lower palpebral conjunctiva in a condition of marked hypertrophic trachoma. Upper palpebral conjunctiva much thickened, has almost a lardaceous appearance. Vascular pannus upper third of each cornea. $V = \frac{4}{18}$ and No. 1 Jaeger. Between July 31st and October 18th, 1902, the everted lids of the right eye were exposed on eleven occasions for ten to fifteen minutes to the action of the focus-tube at a distance from the eye of four to ten inches. The left eye was treated without exposure of the palpebral conjunctiva. After the tenth exposure there was slight dermatitis about the right eye, as well as a small infiltration, exactly like an ordinary phlyctenular deposit in the lower fourth of the corresponding cornea. After the eleventh exposure several similar corneal infiltrations made their appearance. The conjunctival condition of the right eye has markedly improved under the action of the X-rays, a remark that applies equally to the left eye.

CASE II.—W. J., æt. $7\frac{1}{2}$, suffering from trachoma without corneal complications. The lower palpebral conjunctiva and that of the superior fornix were converted into a folded mass of trachomatous material of highly characteristic appearance. The upper tarsal conjunctiva was roughened with numerous small "sago-grains." Between June 25th and August 11th, 1902, the everted lids of the right eye were exposed on ten occasions to the action of the focus-tube, fixed at a distance from the eye which varied from four to eight inches. The exposures were invariably for ten minutes. It was noted that the right side of the face several times became slightly swollen and red after exposure. On July 28th, however, a definite burn (10 mm. by 4 mm.) was found above the outer end of the right upper lid. On July 31st this had almost healed. After two further exposures the condition of the right eye had improved so much that cure seemed to be complete. But a relapse of the trachoma took place nine days later, and this necessitated five more exposures of the X-rays. On October 26th, 1902, the disease as regards the right eye seems to be cured, while the left eye (treated only with 1:2000 cyanide of mercury lotion) is still as bad as ever.

CASE III.—S. O., æt. 6, with well-marked hypertrophic trachoma of both eyes. No corneal complications. Between June and August, 1902, the right eye was subjected to the action of the focus-tube for a period of ten minutes on fourteen occasions, the distance ranging from four to eight inches. The lids were not everted. Although a mask was used, yet more than once the right side of the face became red and swollen after the treatment. On August 7th, 1902, the disease in the right eye appeared to be cured, but a slight recurrence was noted on September 19th, when the lashes were found to be relatively thin and scanty. On October 26th, 1902, after six further exposures, the disease in the right eye seems to be cured.

CASE IV.—A., æt. 12, suffering from very chronic

trachoma of both eyes, with dense, vascular pannus over the upper two-thirds of the cornea, concealing all details of the iris, pupil, etc. Some shallow ulcers were present at the free edge of the pannus. $V = \frac{3}{36}$, and No. 19 Jaeger at 14 cm. After a 5 per cent. argentinine solution had been applied daily for three months the sight had risen to $\frac{4}{18}$. X-ray treatment was then started. During the next three months the right eye was treated on sixteen occasions by exposure for eight to fifteen minutes at a distance of four to eight inches from the focus-tube. The eyelids were not everted. At the time of writing the cornea of the right eye has cleared a great deal, and the sight of that eye is $\frac{4}{18}$. The condition of the conjunctiva, also, is much improved.

CASE V. (High Frequency).—H. L., æt. 4, suffering from trachoma of both eyes. Between July 1st and October 23rd, 1902, the case was treated with the high frequency current, applied at first by means of a sealing-wax and glass and later by a vulcanite electrode over the lids (not everted) of the right eye. The period of exposure ranged from eight to fifteen minutes, but was generally the latter. No complications were noted. The trachoma soon began to improve, and on October 26th, 1902, the disease, as regards the right eye, appeared to be definitely cured.

THE SURGERY OF THE GALL-BLADDER.

By J. McARDLE, F.R.C.S.I.

Surgeon to St. Vincent's Hospital.

I WOULD not dare to occupy the time of this Academy by the recital of ordinary cases of gall-bladder trouble, but in my study of the secondary affections arising in the course of disease of the gall-bladder, and the various ducts with which it is connected, I have come across cases which have so interested me that I thought a brief recital of the salient points in some of them might not be unworthy of your attention. The subject has been so exhaustively dealt with that I hope you will forgive me if my remarks somewhat overlap the pages of even ancient history on this subject.

CASE I.—Mrs. H., æt. 54, was sent to me by Dr. Frost, of Newmarket. She had had several attacks of colic, and jaundice had been fairly constant for some months. Of late jaundice was permanent, and instead of colicky pains she had persistent pain and tenderness under the right costal arch. She had lost flesh, become haggard looking, and looked the picture of misery when she arrived in hospital. Her pulse was small and compressible and her temperature subnormal. For some time vomiting had been persistent and distressing.

I opened the abdomen in this case in the right semi-lunar line, but owing to the extent of adhesions I was obliged to make an incision at right angles to the centre of this line, cutting the rectus. A great deal of time was spent in freeing the great omentum, which was massed round the gall bladder and along the edge of the liver. This done I opened the gall-bladder and gave exit to the stones here shown, and with them a great amount of mucopus; soon there was a profuse discharge of bile. On examining the common duct I found fixed in it a rather large stone, and passing the left index finger into the foramen of Winslow, I brought the stone towards the wound and passed four Lembert sutures over its site in the duct as shown in the accompanying drawings, and hooking up the loops, while the ends were in a clip forceps I cut the duct directly on the stone which was readily turned out with a scoop. Setting the loops free and drawing upon the clip forceps, immediately

closed the wound in the bile-duct. The tying down of the sutures was a matter of only a few moments. Recovery in this case was slow but complete.

In this case the patient was so weak that any prolongation of the operation would not be justifiable, and so I was obliged to hasten the procedure by cutting the bile-duct directly on the stone; you can readily understand that suturing before opening the duct was easily and rapidly carried out, as there was no flow of bile to impede the application of the sutures, and once the stone was removed, traction on the sutures prevented any further discharge of bile into the abdominal cavity.

I consider this a marked advance on the procedure advocated by Halsted, who opens the duct, then inserts a mallet-shaped support to enable him to properly pass the sutures required for closure.

CASE II.—Rev. M. F. consulted me about a general wasting accompanied by weakness brought on by the least exertion. He complained of mental exhaustion after the slightest effort. He always had a great inclination to fall asleep after food, and he suffered much from headache. He had intercostal pain, chiefly in the right side, and referred to the sixth, seventh, and eighth spaces. He also had pain between his shoulders. He had had intermittent attacks of vomiting, occasionally getting up some blood. He also suffered from an irritative cough. For years he had been under treatment for dyspepsia, gastric ulcer, &c., but at no time did he obtain any marked relief.

I examined him carefully, could find no pulmonary or cardiac lesion. The liver was somewhat enlarged, and there was a tender and prominent spot below the right costal arch about on a line with the ninth cartilage. I opened in this region, and a rounded mass, like the gall-bladder, protruded into the wound. On examination I found it to be a tumour at the tip of the gall-bladder the size of a walnut. The liver was very dark and covered all over with greenish-yellow lines, giving a tessellated pavement appearance. I opened the gall-bladder, removed a considerable amount of dark semi-gelatinous fluid. After flushing, I resected the tumour and fixed the gall-bladder to the skin. For a long time this patient had a considerable amount of pain and a very copious flow of dark bile from the wound; gradually this diminished and I was enabled to close the gall-bladder, when all the distressing symptoms above referred to disappeared.

It would be seen that in this case the patient was treated for all kinds of gastric disturbances, and that for years his life was rendered miserable by symptoms varying very much in character, sometimes febrile, sometimes pulmonary, occasionally intestinal, and not unfrequently mental. The removal of the adenoma sections which I now exhibit, relieved him of all this distress, and he is now in the enjoyment of perfect health.

CASE III.—Doctor R. was brought under my care by Mr. Fagan. For years he had suffered from intense epigastric pain, and had frequent attacks of vomiting, when his distress was terrible.

Some months before I saw him, rapid emaciation commenced. He had been, doctor-like, under all kinds of treatment. The contents of his stomach were examined, and the awful word "cancer" had been applied to his condition. I found on examination a greatly dilated stomach and enlarged liver, with a prominent gall bladder, and as the history of the case pointed to extensive adhesions in the neighbourhood of the pylorus I made a rather long incision in the right semi-lunar line, double-ligatured and cut great bands joining the colon to the liver and gall-bladder, thus exposing the gall-bladder for section. On opening this organ I gave exit to a great quantity of bile and mucopus, and I removed, after some difficulty, the stones I now exhibit.

In this case, owing to the unhealthy condition of the gall-bladder I was obliged to bring the peritoneum, freed from its connections, down to meet the bladder wall. For some days we had great trouble with this

patient, but by washing out the stomach frequently we were able to keep him in a state of comparative comfort. He made satisfactory progress. I met him at an operation a few days ago looking the picture of health and having gained three stone in weight since the operation in June last.

It will be seen by the history of this case that the patient was treated for ulceration of the stomach, gastric dilation, and ultimately he was given over as a hopeless case of cancer of the pylorus, when Dr. Fagan correctly diagnosed his case. That the result was not as bad as usually attends cancer is entirely due to Dr. Fagan's action in the matter; and it should be a warning to some and an encouragement to others that all cases with symptoms such as he presented are not necessarily fatal.

CASE IV.—Mrs. M., æt. 32, complained for many years of epigastric pain, vomiting, especially in the morning, and general weakness. As her distress was greatest during the menstrual periods it was thought that all her trouble was of uterine origin; first one ovary, then another was removed, then curetting was done, and later two laparotomies for the relief of adhesions. Each time she was told that she was perfectly well, but her husband, himself a physician in extensive practice, seeing her gradually get thinner and thinner, asked me to examine her. On hearing the history of her illness I concluded that she had a blocking of the gall-ducts. I opened the gall-bladder and removed the peculiar grey stones which I now exhibit, and with them a considerable amount of mucoid material, but no bile, and searching the duct I found this stone blocking it. This was easily extruded by digital compression, and soon after bile appeared in the wound. In this case I fixed the gall-bladder to the middle stratum of the abdominal wall to allow of thorough drainage.

This patient made an uninterrupted recovery, and is now enjoying perfect health.

You will see by the history of this case that a great deal of medical and gynecological talent was exercised in seeking a remedy for a very distressing trouble, the subsequent history of which proved that affections of the gall-bladder often play an important part in the production of symptoms referable to other regions than the right sub-costal area.

CASE V.—Mrs. S. was brought under my notice by her brother-in-law, a doctor in practice at Dublin. I was called to her late at night to a city hotel, where I found her in an epileptic fit. She was in a most pitiable condition. I got a history of frequent sickness, occasional vomiting, and almost constant epigastric pain. On examination I found she had an enlarged liver, and pressure below the right costal arch increased the violence of the spasms. Next morning I had her removed to the private hospital, Holles Street, where I opened the gall-bladder, which contained a tenacious tarry substance, embedded in which I found the very curious stones I now exhibit. I washed out the gall-bladder, and as it was very long, I passed into it a long, thick rubber tube which I fixed to the abdominal wall by two silk-worm-gut sutures. About one o'clock I had a telephone message to say this lady was dying, and on arriving at the hospital I found her in a seizure somewhat like that I had witnessed the previous night. She was cold and almost pulseless. I immediately withdrew the tube and replaced it by a strip of gauze. Almost at once the whole aspect of the patient changed, and soon large beads of perspiration appeared, her face became flushed, and within half an hour she was conscious and expressed herself as much relieved. From this time her progress towards recovery was steady, and since she has not had a single attack such as I have described.

This was the first case in which I had removed from the gall-bladder stones mulberry in character. The history which I have given you is a very striking one, and should show what extreme nerve disturbances may be brought about through the action of irritating materials in the bile-ducts. The epileptic seizures which this lady suffered from could hardly be differentiated from those of brain origin. That they arose from

irritation of the gall-bladder is proved by the fact mentioned in the after-history of the case, the removal of the drainage-tube stopping the fit; and also by the fact that she is in perfect health since I removed the calculi I now exhibit.

CASE VI.—Mrs. L., æt. 50, was brought to me by Dr. J. J. Murphy, complaining of great weakness, headache, rather frequent vomiting, and epigastric pain. She had emaciated very much, and on examination I found the right rectus rigid, the stomach greatly dilated, and she complained of a fulness and tenderness under the right costal arch.

In this case I made an oblique sub-costal incision after Billroth's fashion, so as to have control of the entire pyloric area. I here found a broad band crossing the beginning of the duodenum, the upper portion of which, as well as the stomach, was greatly distended, the stomach particularly being covered with large tortuous veins. I double-ligatured and cut the band, thoroughly freeing the colon and the pylorus. I next opened the gall-bladder, giving exit to a great quantity of dark inspissated bile. After flushing I fixed the gall-bladder to the skin so as to allow for prolonged drainage.

Although very low, this patient made an uninterrupted recovery. Most of the nerve specialists in Europe had treated this lady for nerve trouble of one kind or another, she had been confined to bed for months, had wasted away, and no matter what nourishment she took it was of no avail; all kinds of opinions were expressed as to the cause of this emaciation, and when I saw her the dread word "cancer" had been mentioned as the only explanation of her rapidly failing health. The emptying of an over-distended gall-bladder, the breaking down of surrounding adhesions, and the freeing of the bile-ducts by injection led to an improvement which has left this lady in perfect health for the past five years.

CASE VII.—Mr. S., æt. 52, came under my care with a history of persistent epigastric pain; he was easily fatigued, and the least exertion, and sometimes the pain, brought on excessive perspiration. The pain was referred to the gall-bladder area, to the right shoulder-blade, and to the centre of the spine between the shoulders. He had been under treatment for gastric ulcer, dyspepsia, &c., and of late serious statements were made as to the possibility of malignant disease.

I opened the abdomen in the right semi-lunar line, found the gall-bladder very tense and greatly enlarged, its walls so friable that every type of forceps would cut through with the slightest pressure. Under these circumstances I was obliged to incise the gall-bladder while deep down in the abdomen; to prevent soiling of the peritoneum I kept a douche playing from below the line of incision in the gall-bladder so as to float out the contents after incision. The stones which I now exhibit accounted for the intensity of pain. Recovery in this case was rapid, although the right side pain lingered for some time.

This case had been given over as a hopeless case of cancer of the pylorus, but some medical friend suggested that he might have gall-stones. He consulted Mayo Robson, who diagnosed his case accurately, and offered to carry out the necessary operation; being one of those who still believe in Irish surgery, he elected to take his chance in Dublin, and so I had an opportunity for a second time of removing mulberry stones from the gall-bladder.

He has made a complete recovery, although for a considerable time there was a profuse discharge from abiliary fistula.

CASE VIII.—Dr. C. L. came under my care after having a severe attack of colic for over two years. Previous to these attacks he had on and off suffered from jaundice, and for some months prior to the attack which led him to consult me jaundice had been persistent. Although he had got thin and worn, his spirits were good, and he had a fair pulse and good appetite. The last attack of colic he had occurred four days previous to my examination, and was of such a serious nature that he was obliged to go to bed immediately.

He had been out in the morning; on his return home he felt giddy, then got a sickening feeling, and later intense pain in the right side of the abdomen; this pain lasted only a short time, but he fell on the floor in a state of utter collapse, with cold clammy skin, almost imperceptible pulse, and in a condition bordering on unconsciousness. He rallied after a few hours somewhat, but seemed to fall away again, and when I first saw him, although the jaundice had disappeared, he had all the appearance of one suffering from cholæmia. I elicited the fact that for months no bile had passed away in the motions, but on the fourth day after this attack the motions were well stained with bile.

Believing that this patient had perforation of the common bile-duct, and that bile was pouring into the peritoneum, I opened the abdomen by a very small incision so as to allow free discharge of the bile. This I did without an anæsthetic, as the patient was almost moribund; the result was highly satisfactory. A copious discharge of bile took place, the symptoms gradually subsided, and drainage being completed by the eighth day the small wound was allowed to heal. Since that time jaundice has quite disappeared, and the patient is in perfect health.

In this case for several years the patient was supposed to have malignant disease of the liver; jaundice had been profound at times and had never entirely disappeared, and for many months before I saw him he had been almost black in colour. The latest diagnosis in this case was cancer of the head of the pancreas. A study of the symptoms as detailed above led me to the belief that a stone which had lain for a long time in the common bile-duct had perforated its wall and escaped with a considerable amount of bile into the peritoneal cavity. My reasoning of this case prior to the operation was as follows:—Immediately after the intense pain and collapse, which was very profound, jaundice disappeared, but the evacuations remained white in colour, then after a period of time (four days) that would allow for healing of the perforated duct, the evacuations became bile-stained, the jaundice all the time steadily diminishing, and no further pain being complained of. The removal of the bile from the peritoneal cavity, although the stone was not found, resulted in the complete and permanent cure in this case.

In discussing the foregoing cases, I have avoided all reference to instances of suppurative inflammation of the gall-bladder and its attendant evils. I will only detain you with the account of one more case which serves to illustrate the class of troubles which are by no means uncommon. I allude to those in which adhesions form between the inflamed gall-bladder, the under surface of the liver, and the neighbouring portions of the intestine. In February, 1902, I saw Mrs. W., æt. 65, in consultation with Dr. Burke Sage. She had complained for many years of general sickness, occasional attack of vomiting, and, prior to examination by Dr. Savage, she was supposed to have ague, owing to the recurrence of very exhausting rigors, followed by profuse perspiration. Dr. Savage gave me the history of this case and explained that the rigors were the result of septic absorption from an infected gall-bladder, and called my attention to a hard swelling below the right costal arch, and from this, crossing the upper part of the epigastrium, the patient complained of great tenderness, and during the acute trouble she had great pain in this area. She had broken down in health, and emaciation had become marked, she had a small, weak pulse, and all the appearances of complete devitalisation. In the

hope of affording her some relief, I opened the right hypochondrium and found a great mass of thickened and inflamed omentum covering the gall-bladder and adhering to the liver substance. After section and removal of this I plugged all round with muslin sponges. The gall-bladder wall was so friable that portions come away in the forceps at every attempt to bring it into the wound. I was obliged, therefore, to open it and allow the passage of a great quantity of ochre-coloured fluid, then some broken pieces of gall-stones, and ultimately masses as large as a small egg were removed with a scoop. These had ulcerated through the gall-bladder wall, and were lying in abscess cavities on the under surface of the liver and on the hepatic flexure of the colon. After thorough irrigation I closed the peritoneum round the edge of the cavity from which bile was now beginning to flow. I laid in a large drainage-tube and plugged the wound with iodoform gauze. She rallied soon after the operation, but emaciation still continued, and, notwithstanding all our efforts, she died of exhaustion on the eighth day.

There can be no doubt that early operation would have saved this patient, that the attacks like ague occurred during the formation of an abscess in the line where the stones had eroded, and it is likely that the emaciation so marked before the operation was the outcome of pressure on the under surface of the liver and lesser omentum. Relief of this pressure was not sufficient to allow a restoration of these parts in good time.

In this case the great omentum had become massed round the gall-bladder, adhering to the under surface of the liver and the front of the pylorus, leading to dilation of the stomach, then to distension of the cæcum, and ultimately to marked enlargement of the small intestines, all of which were much hypertrophied.

This is only one of the many cases of this kind which I hope to bring before this section at a later date. My feeling is that such cases are fairly numerous, and that when attacks of cholecystitis have passed off under treatment, there frequently remains such bands as I have described to prolong the patient's trouble, and lead to the belief that malignant disease is present. It is chiefly with the object of directing attention to such cases that I have brought the matter under the notice of the Surgical Section of the Academy.

Lunacy and Law.

THE CARE AND TREATMENT OF PERSONS OF UNSOUND MIND IN PRIVATE HOUSES AND NURS- ING HOMES. (a)

By ERNEST W. WHITE, M.B.Lond., M.R.C.P. Lond.,
President Elect of the Medico-Psychological Association of Great
Britain and Ireland; Professor of Psychological Medicine,
King's College, London; Resident Physician and
Superintendent, City of London Asylum.

My paper to-day is the natural outcome of the address by Sir William Gowers upon "Sanity and Insanity, Lunacy and Law; and the views of a London Hospital

(a) Read at the General Meeting of the Medico-Psychological Association held at the County Asylum, Mickleover, near Derby, February 12th, 1903.

Physician, Particularly in Regard to Private Patients," given at our last general meeting in London. The discussion which followed was hardly worthy of the subject. Most of the earlier speakers, although eminent general physicians, had had little or no experience in the care and treatment of the insane; therefore, when the turn came for those practically acquainted with mental diseases to speak, the hour was advanced, the audience was weary, and an all too exacting brevity resulted.

To-day, the alienist's side of the question can be fairly stated. My wish is to deal with it as briefly and as positively as possible, in order that the discussion may be as thorough as we can make it. We hope all who have had practical experience of single care, and of the treatment of mental cases in nursing homes, will assist us in our search after truth, that the best results may accrue to those who suffer from this, the saddest form of human ailments. I propose to treat the subject by a series of questions and answers, with illustrative cases here and there.

What is certified single care? It is the care and treatment of a duly certified person of unsound mind in a private house. The forms for admission are identical with those for the admission of a private patient into a public or private asylum or registered hospital. There is a like order made by a judicial authority. The medical attendant takes the place of the medical officer in institutions, and must visit at stated intervals, and make the customary reports to the Commissioners and Visitors in Lunacy. A registered practitioner with whom a single patient resides cannot act as medical attendant. The residence is approved by the Commissioners in Lunacy, and the patient visited periodically by them, and the medical and other visitors for the county or borough. Chancery patients are visited by the Lord Chancellor's Visitors in Lunacy. Facilities of access are given to friends by the statute. Thus abuses are guarded against, and there is efficient official supervision.

What are the advantages of certified single care? They seem to be:—

1. Privacy.
2. Domesticity.
3. Secret visits of friends.
4. Avoidance of the stigma of treatment in a lunatic asylum.

1. *Privacy.*—The rich and well-to-do try their utmost to keep secret the mental breakdown of any member of the family for well-known reasons; hence single care at a distance from home is the desideratum.

2. *Domesticity.*—The upper classes often dread the contact of their relatives with other insane patients, and complain of the lack of the comforts of home life in public and private institutions. These objections are now removed by the villa residences attached to public and private asylums and hospitals for the insane.

3. *Secret visits of friends.*—In single care the relatives, if so disposed, can visit unobserved, and much more frequently than they can in an asylum or hospital.

4. *Avoidance of stigma of insanity.*—The sting of certification is in the magisterial inquiry. Young and inexperienced justices often investigate the cases more fully than is necessary. They place too little reliance upon the facts contained in the medical certificates. The terrors of certification are therefore increased. The form of the medical certificate needs revision, the term "alleged lunatic" should be removed. The word "asylum" should be applied only to "an institution for the chronic and incurable insane"; "hospital for mental diseases" should be used for an "institution for acute and curable cases." The terms "lunatic" and "lunacy" should be removed from the statutes, "person of unsound mind" and "insanity" taking their places. For years past the terms "lunatic, lunacy, and pauper" have been forbidden at the City of London Asylum, and the word "asylum" only used for statutory purposes.

What are the disadvantages of certified single care?

1. The absence of skilled medical treatment.
2. Unskilled nursing.
3. Monotony.
4. Insufficient moral control.
5. Interference of friends.
6. Limited supervision.
7. Want of tact and business capacity on the part of the custodian.

1. *The absence of skilled medical treatment.*—The general practitioner, as a rule, knows but little of the treatment of mental diseases. Psychological medicine has only recently become compulsory in the medical curriculum. Moreover, I am sure you will all agree with me when I state that the knowledge of the proper treatment of mental diseases is not to be acquired in the rounds of general practice, or in the consulting room, or even, at present, within the wards of a general hospital.

2. *Unskilled nursing.*—The nurses (male and female) having charge of single patients have, as a rule, had no special training in the management of mental cases, and although perhaps hospital-trained, are quite unqualified for the work. No nurse is qualified to undertake a mental case in single care unless possessed of the Nursing Certificate of the Medico-Psychological Association, which is a recognised guarantee of efficiency. The responsibility with single patients is the greater because the nurse, from want of skilled supervision, is frequently thrown upon her own resources.

3. *Monotony.*—We all know of the many associated amusements and means of recreation provided in institutions for the insane. How dull must be the life of the patient in single care in this respect!

4. *Insufficient moral control.*—The moral decadence of the upper and upper-middle classes when insane is far greater than of the agricultural and industrial populations. Sedentary life, luxury, and high living tend to bad habits. Self-abuse is far more common among private patients than the rate-paid. The moral control—I would rather term it "school discipline"—of our institutions is one of the most potent means we possess for successful treatment. The day is apportioned out to meals, employment, recreation and amusements. The will is made subordinate to those of others, bad habits are corrected, and in many instances our patient is thereby conducted back to rational health.

We admitted in October last a lady who had been under certified care since the previous January, that is, for upwards of nine months. Upon admission she had hallucinations of hearing, her expression was vacant, she walked about aimlessly, did nothing, was faulty in habits, wet, &c., and was drifting to dementia.

We put her under proper discipline, roused her from her lethargy, gave her shower baths morning and evening, which have been continued to the present time. To-day (December 17th) she is industrious with her needle, bright, thoughtful of others, takes part in the associated amusements and recreations, plays the piano and sings well, has regained her self-respect, and is most tidy in her appearance and dress; in fact, is rapidly approaching convalescence and discharge, to the intense delight of her relatives and friends. (She left recovered on February 6th.) Now in single care the sufficient moral control of such a case as this is wanting.

5. *Interference of friends.*—With single patients the friends either get them removed as far from home as possible, satisfy themselves that they are well housed, well clothed, well fed and kindly treated, and visit them only when obliged, for sympathy for the insane relative generally quickly dies; or the patient may be visited much too often, the treatment of the medical attendant and management by the nurse being interfered with, to the great detriment of the chances of recovery.

6. *Limited supervision.*—Certified single patients are taken for profit by needy practitioners, decayed ladies, &c. The official supervision of these custodians is limited. How can we guarantee in all cases humane treatment by nurses, also proper food and environment

at all times? We must remember the best mental-trained nurses remain in the asylum service, or become attached to the better nursing institutes of the Metropolis. Therefore, we have not always the most trustworthy people in charge of the patients under consideration. On the contrary, it is an absolute fact that in a great number of cases the nurses in charge have not had any mental training whatever; frequently they are hospital-trained nurses who are sent out by institutions to whatever case may turn up. I have heard also of asylum laundry maids posing as mental nurses on the books of such institutions.

7. *Want of tact and business capacity in the caretaker.*—Decayed ladies and retired nurses are not possessed of much business capacity, tact or energy in the duties of the house.

What is uncertified single care? It is the taking charge of a person of unsound mind (not under certificate) in a private house or nursing home. I believe hundreds of insane patients of the upper and upper-middle classes are at the present time under care and treatment without being certified in the various counties of England and Wales, not to say the Channel Isles and near Continent. What happens is this: a member of a family, probably with neurotic inheritance, develops mental symptoms. The parents dread certification, and because of the so-called "stigma of insanity" avoid as long as possible the alienist physician being called in, but consent to a "nerve specialist" being consulted. To the neurologist the patient is taken; he duly prescribes and advises. After a short time the symptoms become more pronounced, and home treatment is impossible. The patient must go away. Then the assistance of the decayed gentlewoman is sought, that she may undertake the remunerative care of the insane person; or a nursing home is selected with which some practitioner in a suburban or rural district is connected. The neurologist sees the case from time to time in consultation. He considers himself well qualified to treat this form of disease, and in the interests of humanity (as Sir William Gowers tells us) is accessory to an evasion of the law. Ultimately, in many instances owing to an exacerbation of the symptoms (some attempt at suicide or homicide, &c.), certification becomes imperative, and the patient is sent to a recognised institution for mental diseases. It is from these cases many of us have to glean our recoveries, and a difficult task it is at so late an hour in the day of disease. Let us consider two or three cases to illustrate uncertified single care.

Several years ago I was asked to see a lady suffering from an attack of acute mania. She was at a farm-house at a short distance from a country village. Upon arrival, I jumped out of my trap, and was walking through an orchard to the house, when I beheld the patient among the fruit trees, but in the broiling sun (it was early in August). On either side of her was a hospital nurse, the one pulling one way, the other the other. The patient, a fine, muscular young lady, æt. 25 years, was semi-nude, with many bruises of the neck, chest and arms; her hair was dishevelled, her clothes were untidy and torn, and she did not appear to have been properly washed and attended to. Sedative medicines had been given even to nausea. All were of no avail. The nurses had not had asylum training, the patient was not taking sufficient food, the bowels were not properly looked after, and she was not under proper moral control, although physical control was by no means wanting. Secrecy was the order of the day, so to this out of the way place she was sent, and visited by a medical practitioner daily. The case had been drifting for about ten weeks. I told the father the patient ought to go to an institution for the insane, and she went without delay. She improved at once, and was discharged recovered within two months. This lady has had no relapse, but has since attained success as an authoress.

I will now give you a case of uncertified single care in which the alienist even failed, and you will see the reason. Six years ago I was asked to visit in consultation a lady suffering from puerperal insanity. The

attack had occurred five weeks after parturition, and the symptoms at first were a blend of mania and melancholia. The patient had a very bad family history. The father died of general paralysis of the insane, a brother had for some years been insane, and a sister has since had an attack of mania from which she has recovered. The family is one of typical neurotic inheritance. We had ample means at our disposal, and an excellent opportunity offered for treating an acute case (uncertified) under the most favourable conditions, for the house was a large old manor house with extensive grounds, surrounded on all sides by a wall some ten to twelve feet high. We converted a suite of rooms on the ground-floor into quarters for our patient, who took exercise for hours daily in the old-world gardens, and we secured trained nurses for night and day duty (one had been trained at the City of London Asylum); in fact, converted a most suitable residence into a complete private asylum for one patient. The family medical attendant visited twice a day; I met him in consultation three times a week. This went on for two months. Sometimes the patient was better, sometimes worse. At last I said to myself, "This patient won't get well here. She is not under sufficient moral control. She knows she is at home, in the home of which she has been mistress for years—she does not, therefore, subordinate her will to others. She must be certified and go to a private asylum." The husband, who was tenderly attached to his wife, but a man of sound common sense, agreed with me at once; not so, however, the mother-in-law. I then proposed that Dr. Savage should see the case with me, and the husband said that if he were of the same opinion as myself the patient should go from home, even at the risk of the ire of the mother-in-law. The consultation was held, we agreed, and the patient went to a private asylum, to improve quickly, and to recover under proper moral discipline in about three months.

Now let us consider a case of uncertified single care in which a good and permanent recovery resulted. Some sixteen years back I was consulted regarding a physically healthy young lady, who had developed suicidal tendencies and homicidal impulses. She had threatened to drown herself, and had attempted to strangle her sister with whom she was sleeping. There was no inherited tendency to mental disease. The causes were indolence, self-indulgence, and the habit to which I have alluded as so common in the upper classes. The relatives begged that she should not be certified. Fortunately, I knew a medical man who had been an assistant medical officer in a county asylum, and who thoroughly understood the requirements of our patient. Into his house she went, and was never left night or day. In the morning she had a shower bath on rising. After a light breakfast she was taken for a long ride on a double tricycle with her trained companion. After the mid-day meal she had another tricycle ride, wet or fine. A diet was arranged with limited animal food. The bowels were carefully regulated, and a suitable night draught given when needed. She improved steadily, and recovered completely in about four months to remain well ever since. In this instance an alienist directed the case with a skilled medical attendant, and trained nurses saw the instructions carried out.

(To be concluded in our next.)

THE HÆMATOLYSIS OF CANCEROUS EXUDATIONS.

By L. BARD, M.D.,

Professor of Clinical Medicine at the Medical Faculty of Geneva.

THE red corpuscles dissolve and give up their hæmoglobin in liquid of a specific gravity less than that of blood-serum. We know, moreover, that there are quite a number of substances which exert a solvent action upon them, even when the

medium is of equal or higher density compared with that of blood serum. The compounds possessing this hæmatolytic property not only comprise corrosive or toxic substances, but also certain organic substances as yet very imperfectly known, which only reveal their existence by this hæmatolytic action. It is to the last-named that the name of "lysins" more particularly applies.

In the normal physiological state the various fluids of the organism do not appear to contain any "autolysin," that is to say, any lysin capable of disintegrating the red corpuscles of the subject itself. The solvent action of the digestive juices on the blood is of an altogether different kind and has no bearing on the present question. Saliva has also a solvent influence on the red corpuscles, as was shown by M. Jøsserand, of Lyons, in his work on hysterical hæmosialemesis, but this property is doubtless solely due to the minute proportion of salts present in saliva and its feeble isotonic power. Normal urine leaves the red corpuscles intact unless polyuria has lowered its density below that of blood-serum; the hæmatolysis which is then produced is the result of this difference of density and in no way due to the presence of a lysin.

In the pathological state, the various exudations, the inflammatory serous effusions, and even the urine have not, in the majority of cases, any hæmatolytic action, but this is not always the case, and it is necessary to study closely the causes of the various pathological hæmatolyses. It is important to distinguish clearly between the cases in which hæmatolysis is simply due to a difference in the density of the liquid in question and those in which it occurs independently of the density, and is directly due to the presence of special lysins.

It has long been known that the red corpuscles may undergo solution in circulating blood, thus giving rise to hæmoglobinuria, which can only be detected by the lake-red appearance of the plasma itself, a circumstance capable of secondarily giving rise to hæmoglobinuria. "Lake" serum is met with in many cases of poisoning, and in certain infectious states; it attains its highest degree in the affection, little known in pathology, which has earned the name of paroxysmic hæmoglobinuria.

On the other hand, the conditions under which hæmatolysis can be produced in pathological exudations are very obscure. I myself have sought to discover this hæmatolytical action in the cerebro-spinal fluid, and in hæmorrhagic serous effusions, and in hæmaturic urine. When the liquid to be examined is spontaneously hæmorrhagic, it is sufficient to note the effect it has had on the red corpuscles which it contains; when otherwise, a drop of blood from the subject is added thereto. The red corpuscles are then separated from the liquid, which holds them in suspension, by centrifugation or by a simple deposit; the amount of dissolved hæmoglobin is estimated in the supernatant liquid, either by simple inspection, by colour, or by spectroscopic analysis, or, better still, by the known and extremely sensitive reaction of tincture of guaiacum in the presence of turpentine. We know that a characteristic blue tint is produced between the liquid and the reagent.

Normal cerebro-spinal fluid, the density whereof is higher than that of blood-serum, does not exert any hæmatolytic action on the blood of the subject; hæmatolysis only commences when it is diluted with little more than an equal part of distilled water. In the pathological state, in acute or

chronic meningitis, hæmatolysis is produced with feebler dilutions, but in general it is especially influenced by the lowered density of the medium. In a few cases only the cerebro-spinal fluid assumes the "lake" appearance forthwith without the addition of distilled water, and we might then admit the presence of a pathological lysin; but in all cases of this kind which I have observed up to the present, cryoscopy of the liquid showed a sufficient lowering of density to explain the hæmatolytic action.

This, however, does not hold good in respect of cases of hæmorrhagic serous exudations or hæmaturic urine. In the great majority of cases, pathological effusions do not possess any hæmatolytic influence on the blood corpuscles, which they merely hold in suspension. I believe, however, that hæmatolysis did sometimes occur, and even that it was constant, at least in cases which I have observed up to the present time, whenever these liquids were of cancerous origin.

I pointed out this peculiarity for the first time at the Biological Society, contrasting with it the results which I obtained in five cases of hæmorrhagic pleurisy, of which two were cancerous, while the three remaining cases were of an infectious nature, septic or tuberculous. The liquid of the first two, after centrifugation, contained dissolved hæmoglobin, which was absent from the last three.

I have recently observed several new facts which tend to confirm my earlier observations and help to explain more precisely their significance.

First of all I investigated a certain number of cases of tuberculous or septic hæmorrhagic pleurisy, and in no instance did there occur any hæmatolysis.

Secondly, I was able to satisfy myself, in several cases, that serous effusions of cancerous origin do not possess any hæmatolytic action on the blood of the finger, and that this is also the case with the urine of those suffering from cancer; I repeated the latter experiment on several patients suffering from various forms of visceral cancer. These facts show that the serous exudations, like the urine and circulating blood, do not contain any lysins in cancer, or if they do, not in sufficient quantity to provoke hæmatolysis *in vitro*.

I further remarked on four occasions hæmatolysis of cancerous origin in hæmorrhagic liquids; on the first occasion in the liquid contents of the pouches of a multilocular ovarian cyst of malignant nature; on the second in a peritoneal effusion in connection with large growths of uterine origin; on a third in the hæmaturic urine of a person suffering from cancer of the hip; on a fourth in the liquid of a cancerous pleurisy. The details in the first three cases have a special interest, and are of a nature to throw some light on the clinical aspect.

Let me add that I have never seen a hæmorrhagic liquid of cancerous origin devoid of hæmatolytic properties, so that if not peculiar to cancerous effusions, it appears to be a fairly constant phenomenon in all spontaneously hæmorrhagic effusions.

The fact that hæmatolysis only occurs in spontaneously hæmorrhagic effusions, and that it is absent from serous effusions even of cancerous origin, suggests that this property is associated with the actual contact of the tumour with the fluid—*i.e.*, that a substance is directly derived from the neoplastic cells.

My first two patients were cases of pleuro-pulmonary cancers, the one primary, in the two others as a secondary deposit.

In the case of ovarian cyst, on a post-mortem being made, we found alongside of the pouches containing hæmatolysed blood other smaller pockets containing serous fluid, which did not provoke the slightest hæmatolysis in blood to which it was added. Now the former presented proliferating walls the histological examination whereof revealed the existence of an embryonic epithelial growth, while the serous pouches presented all the characters of multiple adult epithelial tissues of slow growth. †

In the case of symptomatic ascites with large cancerous masses, the serous liquid obtained by the aid of a hypodermic syringe did not provoke hæmatolysis in the blood of the finger. Some fluid subsequently withdrawn with a trocar, at first serous then hæmorrhagic owing to the admixture of blood from the growth itself, possessed very marked hæmatolytic properties.

In the case of the person suffering from cancer of the hip the hæmaturia which I observed occurred suddenly, was very copious immediately after a rather prolonged examination with repeated palpation of the renal region. It continued regularly diminishing for three days. During these three days the urine gave the characteristic reaction of hæmatolysis, while its cryoscopic degree oscillated about 1.40° , an almost normal figure, or at least too high for the hæmatolysis to be put down to a diminution in the isotonic power. When the hæmaturia had completely ceased it was noticed that the urine had no hæmatolytic action on the blood of the finger, from which we infer that the urine secreted by a cancerous kidney does not contain any lysins except during the periods of hæmaturia. ‡

In presence of these facts the question arises whether hæmatolysis is produced in the liquid owing to a simultaneous letting free of a lysin, which is only present in quantity in cases of hæmorrhagic rupture, or whether hæmatolysis does not take place within the tumour itself, the escaping blood already containing free hæmoglobin which would have only to dissolve in the liquid.

Whatever be the value of these hypotheses we must concede that hæmatolysis is not simply dependent on the cancerous nature of the complaint but rather on the direct cancerous origin of the hæmatolysed blood. It is therefore a sign of the local presence of a cancerous growth either primary or secondary.

It will be interesting to ascertain whether blood withdrawn from the growth itself by puncture always presents this hæmatolytic property, and whether there be any practical means of forming a diagnosis of the disease.

It is also possible, and even probable, that hæmatolysis does not occur in all the histological varieties of malignant tumours, or that it presents notable differences of degree following the original nature of the neoplasm.

The destruction of the red corpuscles in a tumour may be, indeed, one of the factors in the production of the cachexia to which such growths give rise. I have elsewhere called attention to the fundamental differences which separate the various cancerous cachexiæ. These variations are dependent on the particular biological properties of the different cellular elements of the organism, which are all capable of giving rise to cancers peculiar to themselves. ¶

Protracted research will be necessary to settle

this question ; in any case the great variety of the cases in which I have observed it up to the present time tends to prove that, if hæmatolysis be not an absolutely general property of all cancers, it is any rate common to a great number of them.

Although the cases in which I have observed hæmatolysis in cancerous liquids are not yet very numerous, I think I may state that the absence of hæmatolysis in a pathological spontaneously hæmorrhagic liquid justifies the assumption that it is not of cancerous origin. It is more difficult to say to what degree the presence of this phenomenon is a trustworthy affirmative indication of a cancerous origin. It is certain that the cancerous lysins are a cause of hæmatolysis, perhaps the most important cause, but it is also certain that there exist others, and much research will be necessary to define their nature and their rôle.

It is obvious that from this point of view hæmatolysis has no diagnostic value, unless it is independent of any lowering of the isotonic power, which can be easily ascertained by cryoscopy. Then, too, we must not forget that certain infective diseases and certain toxins have a hæmatolytic action even on circulating blood.

Lastly the investigation should be pursued, liquid by liquid, serum by serum, no general law being applicable to the latter, as is shown, for example, by the differences observed from this point of view between the properties of pleuritic effusions and the modifications caused by meningitis in the cerebro-spinal fluid. In the latter, hæmatolysis is met in all varieties of meningitis, in tuberculous subjects, and in cerebro-spinal subjects. Its presence cannot, therefore, be taken as a symptom of cancer. In pleurisies, on the contrary, hæmatolysis is absent in tuberculosis and the greater number of infections, and its presence is presumptive evidence of pleural or pleuro-pulmonary cancer.

In hæmaturic urine the question is more complex, the differences without being negligible being less well marked. Hæmoglobinuria is common to several pathological states ; the hæmorrhagic urine of epithelial nephritis also contains dissolved hæmoglobin. Since my attention was drawn to this point, I have had opportunities to study five cases of hæmaturia ; the case, already mentioned, of hæmaturia by cancer of the hip accompanied by intense hæmatolysis ; a case of hæmaturia without hæmatolysis, and probably due to renal tuberculosis ; a case of hæmorrhagic pyelonephritis with much pus ; and a case of subacute epithelial nephritis, in which there occurred a very slight degree of hæmatolysis, not appreciable on inspection, but demonstrated by the action of tincture of guaiacum ; lastly a case of hæmaturia of septic origin, accompanied by concomitant melæna and hæmoptysis, where the hæmatolysis was very marked—at least, as marked as hæmaturia of cancerous origin. These five cases show that urinary hæmatolysis, and also its degree, may be utilised in the diagnosis of cancer of the hip, especially when it is necessary to distinguish it from tuberculosis of that region ; but it is also obvious that it is by no means peculiar to malignant renal growths.

It is evident from the above facts that the investigation of hæmatolysis in spontaneously hæmorrhagic pathological liquids, both in the excretions as well as in the exudations of the serous membranes, deserves to become a routine clinical method of investigation.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.
MEETING HELD FRIDAY, FEBRUARY 13TH, 1903.

DR. VIVIAN POORE, F.R.C.P., Vice-President, in the Chair.

MR. H. L. BARNARD related the notes of nine cases illustrating

THE DRAINAGE OF THE KNEE-JOINT IN ACUTE SUPPURATIVE ARTHRITIS.

He pointed out that few cavities of the body are so difficult to drain as the knee-joint. The usual method by lateral anterior incisions drains only the anterior half of the joint. An instrument cannot be passed from before back between the femur and tibia so as to make a counter opening behind, as recommended by some surgeons, unless the joint be flexed or the ligaments be softened and disorganised by suppuration which is not usually the case. In 1888 Sir Frederick Treves advocated continued irrigation, and published two cases of free mobility after its use. (*British Medical Journal*, July 7th, 1888.) These cases appear to have been mild infections, as seven subsequent cases treated by other surgeons in this manner gave two deaths, and only one mobile joint. The "open method" by a transverse incision, dividing the patella and fully flexing the knee, is a forlorn hope of conservative surgery. A successful case of its use is narrated by Dr. Walter Whitehead, (*British Medical Journal*, June 21st, p. 1525.) The anatomy of the knee-joint shows two capacious pouches behind. They reach above the condyles posteriorly, where they are covered by the heads of the gastrocnemii. They are separated from one another by a complete septum formed by the crucial and other ligaments. The external pouch sends a bursal extension down the leg along the popliteus tendon. When the knee-joint is extended these two pouches are shut off from the front of the joint by the tight coaptation of the femur and tibia. When distended with pus they rupture into the depths of the popliteal space where the sepsis is liable to involve the vein. The abscess then tracks down the calf and up the thigh, making drainage of both tracks almost impossible. The pouches should be freely opened by two-inch incisions in the line of the leg made by cutting on the condyles where they can be felt projecting on either side of the popliteal space when the leg is fully extended. In order not to wound nerves when the skin has been divided, a blunt instrument should be used to scrape down to the capsule ; this may be freely divided with the knife. The knee is then flexed to relax the structures, and tubes are inserted on each side. In eight of the nine cases treated by this method the temperature fell to normal in from thirty-six hours to a week. Massage—downward in front and upward behind—greatly assists the evacuation of pus from the deep pockets. An instructive case was then narrated where the posterior pouches were not drained ; they burst round the popliteal vein and pyæmia followed. The nine cases given in this paper were consecutive. The four traumatic cases gave the best results. Two had good movement, one had some movement when he left the hospital, and one had fibrous ankylosis. The five cases of auto-infection were most unsatisfactory, two were amputated, one for feeble repair and persistent sinuses in an old woman, æt. 65, the other for a tuberculous cavity in the end of the femur infected with erysipelas. The two cases apparently due to leucorrhœa were most unsatisfactory. Sinuses persisted although the temperature was soon reduced to normal. It is claimed that the method of posterior drainage will cope successfully with the immediate dangers of sepsis. The final condition of the joint depends rather on the cause of the suppuration. Subacute cases of suppurative arthritis of the knee due to auto-infection should be treated by the usual lateral patella incisions and irrigation. Should the temperature remain above normal, the posterior

pouches may be incised later. All acute cases, especially if due to punctured wounds, should be laid open freely at once, both in front and behind.

Mr. W. G. SPENCER observed, with regard to the posterior pouches of the joint, that if they were opened from behind there was much more danger of injuring the popliteal nerves than if opened from within by cutting down upon a probe or sinus forceps. Discussing the merits of the open method he related the case of a publican on the verge of delirium tremens, in whom an injury to the knee-joint was followed by necrosis of the patella and suppuration. In this case he opened the joint and recovery ultimately followed with the joint ankylosed in the middle position. He regarded the open method as a favourable alternative in cases that would otherwise have to be treated by amputation.

Mr. CLUTTON advocated small incisions and washing out the joint, with immediate suture, a method which had given excellent results in a number of cases usually treated by more energetic measures, e.g., extensive incisions, washing out, erosion, &c. He looked upon multiple incisions as a *dernier ressort*, and as really only the last step towards amputation.

Mr. MARMADUKE SHEILD claimed that the good results related by the author were not confined to the London Hospital, but that elsewhere acute suppurative arthritis was generally recovered from with movement of the joint, especially in young and otherwise good patients. He referred to five cases of his own of acute gonorrhœal infection of the knee-joint treated by incision on the inner side of the patella, and flushing with a solution of the biniodide of mercury, the wound being closed at once, with really surprising results. The temperature fell, the pain disappeared, and so on, and when contrasted with the old plan of treating such cases by means of the icebag, &c., they certainly compared favourably. He recalled the striking results obtained by Dr. O'Connor, of Buenos Ayres, with this method of treatment. This surgeon, indeed, went a step further, for he treated in the same way joints with what was generally described as rheumatic effusion which, in many instances, were obviously nothing of the kind, but of the nature of a pyæmic infection, such as occurred in puerperal women and after neglected abortion. Similar septic suppuration was met with in servants who lived in badly drained houses. He thought that in some cases drainage might advantageously be done through posterior incisions, but advocated the employment of large tubes with frequent irrigation of iodide of mercury solution, though in gonorrhœal cases the nature of the fluid was of less importance.

Mr. WALLIS referred to three cases of gonorrhœal effusion into the joint, which he had opened and washed out with normal saline solution, with extremely satisfactory results, in that the patient recovered with perfectly movable joints. He did not think that it was good practice to wash out the joint with strong antiseptic solutions, which tended to further irritate the synovial membrane.

Mr. BARNARD, in reply, pointed out that he only advocated the posterior incisions in very severe cases, especially in cases of suppurating wounds of the knee or wired patella cases which went wrong, cases which were the horror of the surgeon. Such cases, he urged, ought to be drained in this way from the beginning. He asked Mr. Sheild whether there was pus in all his cases in view of the fact that the great majority of these cases got well without any incision at all. He asked Mr. Spencer whether he or anyone had ever succeeded in introducing a probe or sinus forceps into the posterior pouches from the front, a feat which he himself had never been able to accomplish, even in the post-mortem room.

Mr. SPENCER replied that he was, of course, contemplating cases in which the ligaments of the joints were more or less disorganised and relaxed, and he agreed that it would hardly be practicable in a normal joint.

Mr. SHEILD added that in all his cases the joint was

distended with turbid serum, containing large flakes and lumps of purulent lymph rich in gonococci.

Dr. STANLEY BARNES, introduced by Sir William Gowers, read a paper on a case of

LOCAL PANATROPHY.

In this communication an account is given of a case similar to the one shown by Dr. Harry Campbell at the Clinical Society on October 24th, 1902. Nothing of importance could be ascertained in the family history of Sir W. Gowers' case, none of whom were similarly affected. She had led a healthy open-air life, and had been free from disease except for an attack of "intermittent fever" as a child. She was thrown from a horse at 24, and a year later fell on to the back of her head whilst skating, but neither accident was severe enough to keep her in bed. At the age of 32 she first began to have facial neuralgia, which has persisted at intervals ever since; the pain has always been worse just before the onset of menstruation, and with the onset of the climacteric the neuralgia has been less severe, and the intervals of freedom from pain have been longer. At the age of 34 she noticed that she had difficulty in raising the left arm, and this weakness became more pronounced for the next two months. A friend then happened to see the shoulder and thought she had dislocated it. A few weeks later, in 1884, she was seen by Sir W. Gowers in consultation, and it was found that besides atrophy around this shoulder various other patches of atrophy were present. Despite treatment little improvement occurred, but no further progress of the disease was noticed till 1892, when, at the age of 42, the nose appeared to be becoming deflected. At the age of 50 a slowly progressing right facial paralysis came on, becoming almost complete in twelve months; considerable recovery has since occurred. The patient is now a healthy woman of 52, with no sign of visceral disease. There is no sign of old hemiplegia, &c. The bones of the skull are not asymmetrical, but there are several patches of atrophic skin on the face (both sides) and behind the temporo-maxillary articulations. There is a partial right facial palsy of the peripheral type. Possibly due to implication of the facial nerve in the atrophic patch near the mastoid. Many remarkable patches of atrophy are present elsewhere. Over the largest and most severe of these, skin, subcutaneous tissue and muscle are wasted, and in one case the subjacent bone is also atrophic. The skin in these patches is soft, very thin, devoid of hairs, and of natural colour. Isolated patches of muscle tissue have wasted, the patches corresponding to the atrophic skin covering them. The patches are mainly present on the trunk behind the left shoulder and right arm and leg; they are asymmetrical placed, and are of very irregular shapes. There is no anæsthesia over them, nor can the reaction of degeneration be found in the muscle involved.

Dr. SAVILL suggested that the case belonged to the class of *morphœa atrophica*, and he referred to the case of a woman whom he had seen eight years before when she presented the appearances of what Erasmus Wilson called *morphœa lardacea*, the patches subsequently becoming atrophic. He questioned the existence of facial paralysis in the author's case, and drew attention to the history of injury, which tended to confirm the idea that these cases were of neurotrophic origin.

The PRESIDENT alluded to a case he had seen of a patient who presented patches of atrophied skin, and who exhibited curious recurrences of local dilatation of the blood-vessels.

Dr. STANLEY BARNES, in reply, insisted on the fact that no evidence of vascular disturbance had been discovered in this case. The neuralgia from which she suffered was, or became, bilateral. He adhered to his statement that the patient was suffering from paralysis of the face, and gave his reasons for that belief. There was a total absence of any sclerosing tendency.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, FEBRUARY 6TH, 1903.

MR. RICKARD W. LLOYD, President, in the Chair.

SEQUELÆ OF ENTERIC FEVER AND THEIR TREATMENT.
DR. SEYMOUR TAYLOR, in opening the discussion,

defined sequelæ as conditions occurring after the end of the febrile process, when the temperature has been normal for two days and two nights. After mentioning the difference in type of epidemics occurring in Great Britain and in other climates, he called attention to the fact that many patients state that their health is much improved after an attack of typhoid. Dr. Taylor then analysed fifty-six cases of relapse, and pointed out that in many cases a change of diet, starchy food, or an enema of purge seemed to bring about the relapse, although in many cases no cause could be assigned. Under respiratory sequelæ tuberculous disease was mentioned, latent trouble being frequently aroused to activity. Laryngitis with necrosis might occur, leading sometimes to emphysema of the neck and a condition resembling Ludwig's angina. As regards the circulatory system, thrombosis, nearly always of the lower limbs, was fairly common. The extent of thrombosis was often large, and the clot might extend into the vena cava. Dilatation of the heart, with valvular incompetence, was also a sequela. Nervous sequelæ were not uncommon, such as definite insanity or some moral obliquity. Aphasia might occur, and also peripheral neuritis. Besides constipation and meteorism, peritonitis and perforation might be sequelæ, peritonitis being possibly started by bacilli in a gland, or by infection from the appendix or from the gall-bladder. Perforation might be suspected when with a falling temperature the pulse becomes rapid, associated with the characteristic faces. Sequelæ affecting the skin, subcutaneous tissues or bones were such as noma, gangrene, and necrosis. These were not necessarily due to the intensity of the fever, but to the condition of the individual.

Dr. WILLIAM HUNTER took a wider view of the definition of sequelæ. He regarded them as complications which occur apart from the ordinary course of typhoid fever, and with causes different from typhoid fever. He analysed the cause of death in fifty cases; 48 per cent. died from perforation, 20 per cent. from pneumonia, 8 per cent. from asthenia, 6 per cent. from heart complications, including pulmonary thrombosis, heart thrombus and fatty heart. In 10 per cent. lung troubles other than pneumonia caused death, hæmorrhage in 6 per cent, and erysipelas in 2 per cent. Dr. Hunter said that the mortality was greater formerly, probably in consequence of unsanitary conditions. This would account for the greater severity of epidemics in some German towns. As regards the influence of treatment on recovery, probably 75 per cent. of patients would recover without treatment, another 15 per cent. would recover in good hygienic conditions, and 2 per cent. more might recover under strict hydro-therapeutic treatment. It was remarkable how very little inflammation occurs in connection with typhoid ulceration. Peritonitis hardly happens except as the result of perforation. As regards treatment, almost all the benefit resulting from pathology goes to the prevention of the disease. The operation for perforation was a great departure, with a considerably increasing percentage of recoveries; intestinal antiseptics is important; and baths, which are a colossal task, may diminish the mortality by 2 per cent.

Dr. A. ELLIOT observed that from the military point of view the most important sequela of the epidemic in South Africa was disability, physical and mental. In slighter cases men were able to do light work at the base, but for a long time the hardships of trek were quite beyond their powers. In commissioned ranks the greatest stress was on the nervous system, producing slowness of cerebration and lack of decision, or rendering the patient unfit for responsible duty in the field. Of specific sequelæ the most common, and perhaps the most important, was phlebitis, variously estimated as occurring in 5·6 per cent. to 25 per cent. of the cases. In epidemics in England and America the frequency is estimated at from 1·9 to 3·8 per cent. As regards the cause of the increased frequency, Washbourn suggested that it was due to tinned food and want of fresh vegetables. But these lead rather to scurvy and deficient coagulation of blood. Another

suggestion was the wear and tear of marching. But an equal proportion of cases occurred in the cavalry and artillery. Professor Wright found that the coagulability of the blood is increased during convalescence from typhoid. This, he thinks, is due to an excess of lime salts from the exclusively milk diet. But in South Africa there was a notable lack of fresh milk. Probably all that can be said is, that this sequela was due to the bacterial invasion of the vein walls under conditions of lowered resistance. Embolism, although comparatively frequent in thrombosis associated with influenza and gout, was markedly absent in the thrombosis following typhoid. Bradycardia occurred in one case, but might possibly have been due to an excess of digitalis. Tachycardia was a much more frequent and persistent trouble. As regards the alimentary system, hepatitis with enlargement of the liver without suppuration occurred in one case. There was jaundice in one case associated with fatal pneumonia. Suppurative appendicitis closely followed enteric in one case. Probably it was due to an enteric ulcer in the appendix. Two cases of enteric immediately followed appendicitis. There was late perforation in one patient who had been on ordinary diet for a fortnight. A recent ulcer in the ileum was found to have given way. Two cases of parotiditis occurred during convalescence; in both there was suppuration. As regards dysentery, out of thirteen cases occurring during the disease or convalescence, six proved fatal, while of six patients who had dysentery before enteric all recovered. There were nine cases of joint affection, including six arthralgias, two cases of arthritis with effusion, and one case of purulent effusion.

Mr. GARRY SIMPSON did not consider it safe to say that a patient was convalescent till the temperature had been normal for three weeks, as the bacillus might still be found in the stools and urine. He objected to the treatment of hæmorrhage by large doses of opium, as thereby the bowels were confined and the growth and virulence of the bacilli favoured.

Dr. J. E. SQUIRE observed that climatic and other conditions might modify the course and symptoms of the disease, but not in essential points. He thought it debatable whether two days of normal temperature could be taken as the sign that the illness proper was over. In many cases in Suakin the febrile condition continued for two or three months, but was probably due to malarial complications. He regarded thrombosis as a comparatively frequent sequela. Pneumonia is more often a complication, and hæmorrhage and perforation also rather accidents occurring during the disease. Joint affections occurred after several cases in the Soudan, chiefly those resembling malarial fever, with enteric symptoms, rather than true enteric fever.

Dr. ALDREN TURNER called attention to certain sequelæ affecting the central nervous system, such as hemiplegia and myelitis, which were clearly due to arterial changes comparable to those occurring in syphilis. Obliterating endarteritis was not uncommon. Peripheral neuritis similar to that resulting from alcoholic poisoning was a sequela. Another condition might be described as typhoid spine. In one case this came on two months after convalescence and lasted for four months.

Dr. E. A. SAUNDERS said that it was of great importance to separate the sequelæ due to the *Bacillus typhosus* from those due to other micro-organisms. There was very little doubt, for instance, that there exists a true appendicitis. The case of hepatitis referred to by Dr. Elliot was probably also a true typhoid infection. Other sequelæ might be due to staphylococci and streptococci, or to the *Bacillus coli*. Such post-typhoid affections are abscesses—*e.g.*, in the larynx—parotiditis, boils, bedsores, &c. It seems probable that many of the symptoms of severe cases of typhoid are attributable to simultaneous affection with the *Bacillus coli communis*. Dr. Saunders thought that the increased prevalence of thrombosis after typhoid in South Africa might perhaps be due to the existence of this organism in a condition of increased virulence. The recognition of such compound infection:

may help in interpreting many of the anomalous symptoms of typhoid fever.

Dr. A. WHITFIELD drew attention to the frequency of severe and persistent furunculosis after enteric fever. It generally makes its appearance between six and twelve months after the attack. It might be worth while to try to prevent it by systematic treatment of the skin in the early state of convalescence, and by attempts at intestinal antiseptics during the course of the primary disease.

Mr. LLOYD remarked that the typhoid poison would be added to any other disease that the patient might be suffering from at the time, and that what might appear to be sequelæ of typhoid might be more properly ascribed to the previous constitutional state. Thus, anæmia or malaria might predispose to thrombosis in an attack of typhoid, and gonorrhœa or syphilis to pseudo-rheumatism of joints or other tissues.

THE ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD FRIDAY, FEBRUARY 6TH, 1903.

In the absence of the President, Professor FRASER took the Chair.

Dr. E. H. TAYLOR showed two specimens of the new-born infant to demonstrate the topographical anatomy of the stomach and other abdominal viscera.

Drs. E. H. TAYLOR and E. J. WATSON made a communication on the value of X-ray photography in connection with the structure of bone. Dr. Taylor dwelt specially on the temporal bone in connection with operations for the results of suppurative middle ear disease. Dr. Watson exhibited many beautiful skiagrams showing the structure of different bones.

Professor FRASER showed two cases of "Congenital Absence of the Left Lateral Half of the Diaphragm." The one case occurred in a male fœtus about the fourth month, which was otherwise perfectly normal. The under surface of the left lung lay upon the suprarenal capsule, the stomach and the left lobe of the liver. The left free margin of the central part of the diaphragm ran as a strong band from front to back, slightly external to the pericardial sac, and above the left suprarenal capsule and kidney. The other case occurred in a full-time female fœtus, and was only one of many abnormal features present. The lungs were well developed, and the right pleural cavity was perfect. The left contained the lung, several coils of the small intestine (which was well developed), and the left lobe of the liver projected into it. This cavity also communicated with the pericardial sac, the upper half of the left wall of this sac being absent. Between the two pleural sacs dorsal to the heart, but more to the right than the left, a large cavity was found containing a well-developed stomach, pancreas and spleen. This cavity communicated with the general abdominal one through an aperture in the position of the foramen of Winslow. On slitting open the cavity of the mouth and pharynx on the left lateral aspect, it was found that there was no œsophagus present, the lower part of the pharynx expanding into the cardiac end of the stomach, which, as has been already stated, lay dorsal to the heart between the two pleural sacs. The colon lay entirely to the left of the middle line of the body.

THE ANATOMY OF THE SKULL STEREOSCOPICALLY DEMONSTRATED BY X-RAYS.

After some introductory remarks, Dr. HAUGHTON referred to the difficulty of interpreting a "single skiagram," and said it required a long apprenticeship to such negatives before accuracy could be arrived at. The difficulty of "reading" a "single skiagram" arises from several causes. The X-ray picture is an example of uniplanar projection of multiplanar objects. This causes superposition of shadows. Then X-rays being a diverging cone, causes magnification and obliquity distortions. These sources of in-

accuracy in the "single picture" were all used up and eliminated by the beautiful stereoscopic method of Röntgen photography first described by McKenzie-Davidson. By this method a reproduction of the skull could be produced, perfect in contour and perspective. Dr. Haughton then showed by diagrams on the blackboard how all these sources of inaccuracy were eliminated in the stereoscopic method; and afterwards, in the reflecting stereoscope, showed prints of the skull-base and lateral views, in which the following points were well demonstrated:—*Relations of groove for lateral sinus to mastoid air cells, mastoid emissary vein, internal auditory meatus, external auditory meatus, cochlea, semi-circular canals, canal for internal carotid artery, foramina in base of skull, air cells, sphenoid, ethmoid, frontal sinus, antrum of Highmore, turbinated bones, vomer, dentition (unerrupted bicuspid and wisdoms), clinoid processes, grooves for middle meningeal artery, &c.* Dr. Haughton mentioned that this was a preliminary communication on bone structure in man and the lower animals, which he hoped to bring before this Section later on in the Session.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, FEBRUARY 5TH, 1903.

W. WINSLOW HALL, M.D., President, in the Chair.

MR. NOBLE SMITH read a paper on the

TREATMENT OF CONGENITAL DISLOCATION OF THE HIPS, with especial reference to Lorenz's method of bloodless reduction. He said that successful treatment depended on the condition of the bones, and this was stated to be more favourable in early age. X-rays had shown that this was not absolutely the fact, as the bones had been found in a favourable condition, even at the age of 30. It had also been stated that sufficient time had not elapsed to judge of the results of getting the head of the femur into the acetabulum. This also was not the fact, as similar, but not so efficient, treatment as Lorenz's has been adopted for some years past. He mentioned a case in which, six years ago, there was 2½ inches shortening. By means of a Liston's splint and extension a natural position was obtained in three weeks. The patient was kept on the back for eight months, and then got about with the weight off the joint. At the end of two years the bone was very near the acetabulum, and the legs were exactly the same length. Three years after getting about, the child was walking naturally, and there was only a quarter of an inch shortening. The result was excellent, though not as thorough as by Lorenz's method. The author then gave a description of Lorenz's method, illustrating the procedure on a child suffering from the disease. The adductors of the thigh are first put on the stretch, and manipulated by chopping with the edge of the hand and rubbing. After a time the muscles gave way. Then the posterior muscles are dealt with until the foot can be brought up to the side of the head. The anterior muscles are next stretched by bending the thigh backwards with the knee bent, the patient lying on the opposite side of the body. With the patient once more on the back, and the knee bent, the head of the femur is gradually worked down into the acetabulum. In many cases the head of the bone can be heard slipping into the socket. The front of the capsule is then stretched by working the thigh outwards with the knee bent, until, with full abduction, the hollow in the front of the thigh is filled up, and the head of the bone cannot escape. The limbs are finally fixed in a position of abduction by means of plaster-of-Paris. Lorenz has shown that this position must be retained for six months. The thighs are then brought down half-way and put in plaster again, and are gradually straightened at the end of two years. As to the suitable age for reduction, for double dislocation the best results are obtained up to six years. For a single dislocation the time may be extended to nine years of age. Older patients must be prepared by preliminary stretching and exercise, but Lorenz had cured a patient, æt. 28. He pointed out the advantages of the bloodless method, viz. :—That it was a perfectly safe procedure, even such accidents as fracture of the femur leading to no ill-effects;

that there was no risk of a stiff joint, with consequent crippling for life; that young children were not affected by being kept off the feet for two years, and, as a matter of fact, patients were not kept lying down the whole time, but pushed themselves about on a stool, which was shown. A block was also shown which was very useful for placing under the thigh during manipulation.

Mr. OPENSHAW had used methods of manipulation for seven years, and in 30 cases had had good results in about a third of that number. Lorenz's method had been gradually improved, especially in the retention of the fully abducted position for six months. In this time probably the gluteal and other muscles became shorter and prevented redislocation. Possibly the head of the femur might ultimately make its way through the capsule into the joint, but often the bone could not be got into the acetabulum. In the open operation, if the cartilage was not interfered with, there was no ankylosis.

Mr. JACKSON CLARKE quoted a post-mortem on a child dying of diphtheria, one month after Lorenz's operation, to show that the head of the femur could be replaced in the acetabulum. The glenoid ligament is sometimes so thick as to make replacement very difficult. He called attention to friction bands, underneath the plaster splints, whereby the skin could be kept in good order. Difficulties in the treatment were due to parental neglect and indifference to this kind of work. In cases difficult of reduction, much ecchymosis might be caused. In such cases it was better to do a preliminary operation of stretching or dividing muscles.

Mr. DANIEL said that much improvement had taken place in Lorenz's methods, and instanced the thoroughness of the work of applying plaster-of-Paris splints. He thought that cases treated by Lorenz's methods contrasted most favourably with the results of the open operation.

Mr. PEYTON BEALE wished to know what happened to the ligamentum teres after reduction. Did it shrink or did a new ligament form?

The PRESIDENT said that the subject was of importance to the general practitioner, with whom the fact that Lorenz's method did not endanger life or limb would have great weight.

Mr. NOBLE SMITH, in reply, said that the condition of the ligamentum teres had not been verified. He also protested against the imaginative descriptions of the newspaper reporter.

Mr. SIDNEY SPOKES read a paper on "The Immediate Regulation of Misplaced Teeth," in which he advocated forcible advancement of the misplaced tooth at once into its proper position. He showed an instrument invented by Dr. Grevers, of Amsterdam, whereby this could be readily accomplished. The method, he remarked, was particularly suitable to children, in whom the bone yields readily, and the blood-supply to the pulp is not easily interfered with.

Mr. SEFTON SEWILL said he had performed the operation on patients at various ages up to seventeen, always with complete success. Objections had been made that the blood-supply might be ruptured, but he had never seen this occur. The amount of discomfort following the operation was remarkably slight.

THE PRESIDENT asked whether much pain attended the operation, and what age was most suitable.

Mr. SIDNEY SPOKES in reply said that so little pain was caused that the operation might be done without an anæsthetic. As regards age, he had operated on a patient, æt. 25, with satisfactory results, but children were the most suitable patients.

LARYNGOLOGICAL SOCIETY OF LONDON. MEETING HELD FEBRUARY 6TH.

The President, DR. P. McBRIDE, in the Chair.

MR. R. LAKE showed (1) a microscopic specimen of "pseudo-pachydermia," from the *processus vocalis* in a tuberculous subject; (2) a case of "tuberculous laryngitis."

MR. CHARTERS SYMONDS showed a case of "paralysis of the left vocal cord," the result of lead poisoning in a girl, æt. 18. The patient exhibited the usual paralysis of the limbs and a marked blue line on the gums. The rarity of the laryngeal affection was commented upon.

Sir FELIX SEMON drew attention to the fact that the form of paralysis varied with the poison, lead having a selective action on the abductors.

Dr. PEGLER showed a septotome for Moure's and other operations for deflected septa.

Mr. DE SANTI showed a case of "unilateral enlargement of the thyroid gland" (right) in a woman, æt. 50, which had caused great displacement of the larynx and trachea. The patient had had attacks of dyspnoea. Mr. De Santi proposed to remove the right half of the thyroid.

Dr. BROWN KELLY showed microscopical sections of new growths of the type of "bleeding polypus of the septum."

Sir FELIX SEMON showed a "case of tabes" with early and unusual implication of various cerebral nerves in which the chief features of interest were: (1) complete paralysis of the soft palate; (2) in spite of which the swallowing of fluids did not produce regurgitation when the patient drank slowly; (3) non-implication of the tongue until a few days previously; (4) the vacillation in the symptoms, the paralytic phenomena being distinctly more marked on some days than others; (5) the absence of laryngeal crises.

Dr. DONELAN showed a case of "ankylosis of the left crico-arytænoid articulation" in a woman, æt. 23.

Mr. HUNTER TOD showed a case of "polypoid tumour of the nasal septum" in a woman, æt. 33, of three months' duration, and which bled freely. A microscopic section was exhibited.

The case was discussed by the President, Dr. W. Hill, Mr. Waggett, and Dr. Dundas Grant.

Mr. W. H. B. STEWART showed a case of "laryngeal obstruction," which had been exhibited at a previous meeting (January, 1897). He also showed a case of "frontal sinus disease" in a man, æt. 26, which showed great expansion of both sinuses.

Dr. DUNDAS GRANT thought there was softening of the bone, most likely due to periostitis in connection with the sinus suppuration. There was probably a specific element.

Mr. STEWART replied that the patient had been treated with anti-syphilitic remedies with no beneficial result.

Mr. WAGGETT showed a case of "growth in the neighbourhood of the right Eustachian tube" in a man, æt. 69. The growth was considered to be malignant, and in reply to the question as to the advisability of a palliative operation, Mr. DE SANTI considered that no operative procedure would be justifiable.

Dr. FURNESS POTTER showed a case of disease of both frontal sinuses in a man, æt. 29, in which he considered the indications were not such as would justify a "radical operation."

Dr. DUNDAS GRANT showed a case of "persistent œdema of the larynx," probably amyloid in character, in a middle-aged woman.

The case was discussed by Sir Felix Semon, Drs. de Havilland Hall, Brown, Kelly, and MacKintosh.

Dr. W. HILL showed a case of "tuberculous disease of the larynx," with intra-arytænoid growths, but with no evidence of pulmonary involvement.

THE MEDICO-LEGAL SOCIETY.

The last meeting of this society was held at 20, Hanover Square, on TUESDAY evening, February 10th, 1903. Sir WILLIAM COLLINS, M.D., M.S., L.C.C., presided.

MEDICO-LEGAL POST-MORTEM EXAMINATIONS.

Dr. HARVEY LITTLEJOHN, of Edinburgh, reopened the discussion on this subject, and insisted on the importance in England of greater precision in the conduct of autopsies for medico-legal purposes. Various members took part in the discussion, and whilst the desirability of procuring skilled pathologists for such investigations was urged, the difficulty of obtaining expert assistance at the present rate of remuneration, especially in country districts, was clearly indicated. It was also shown that there was need for much improvement in the practical training of students in the conduct

of pathological examinations and the management of medico-legal investigations.

THE WHITECHAPEL MURDERS.

Dr. GORDON BROWN presented a critical paper on the so-called "Jack the Ripper" murders, illustrated by diagrams and photographs. The conclusion of a careful analysis seemed to indicate that the still undiscovered offender was probably a man who had been trained in slaughter-house procedures, and was the subject of that form of sexual perversion to which the term of *sadism* has been applied.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 15th, 1903.

THE RADICAL CURE OF HYDROCELE.

In his paper read before the Société de Chirurgie, Dr. Fangère remarked that hydrocele, usually styled idiopathic, was not the less provoked by a lesion of the epididymis, as a careful examination of the organ would show; spermatic cysts, traumatism, rheumatism, syphilis, &c., only acted through the influence of the gland. He would not go into the pathological anatomy or the symptoms of the affection, but he would say a few words on the different varieties of hydrocele and the treatment. Besides the multilocular, diverticular, chylous and milky varieties of hydrocele, there was the infantile or congenital hydrocele and hydrocele in woman. The infantile variety was generally attributed to a traumatism during delivery. It got well spontaneously.

Congenital hydrocele was not, properly speaking, a hydrocele, it should be considered as a vaginalo-peritoneal hydrocele, as in reality it was an accumulation of peritoneal serosity in the tunica vaginalis. It was called congenital because it was due to a congenital malformation and not because it was itself congenital. The lesion was due consequently to an arrest of development. In the normal condition the testicle descended into the scrotum, carrying with it a fold of the peritoneum. It became invaginated in the inguinal canal like the finger of a glove, and formed in this way the tunica vaginalis. That canal was only temporary, became obliterated by degrees, and finally in its place was found a thin cord called the ligament of the vaginalis. At birth the canal existed still, establishing a communication between the vaginalis and the peritoneum, but the obliteration was effected rapidly in a few days. Where the obliteration is not effected, congenital hydrocele was the result. Although observed at every age, congenital hydrocele was more frequent between the ages of three and ten; spontaneous *reductibility* in the horizontal position or provoked by pressure was the fundamental character of that kind of hydrocele, that benign affection, which called for treatment only because it favoured the production of a hernia, was chronic in its evolution, and disappeared frequently spontaneously, especially in the child, by obliteration of the canal.

Hydrocele in the woman consisted in a serous cyst of the labium majus. As regarded the treatment, numerous were the methods recommended: puncture followed by a modifying injection, tincture of iodine, iodoform and ether, nitrate of silver and chloride of zinc. All those injections were more or less painful, and followed by considerable inflammation of the scrotum, that of the first and last-named more particularly. The chloride of zinc solution was composed as follows:—

Chloride of zinc, grs. xvj.
Water, ʒiij.

After having removed one or two ounces of the

liquid, from five to twenty drops of the solution should be injected by the ordinary hypodermic syringe. Inflammatory swelling was the result, but quickly subsided, and in two or three days the patient was cured. The method was much less painful than that of tincture of iodine.

The radical cure by operation was the best method of treatment, since antiseptics had so much facilitated the use of the knife. Several methods were employed—simple incision, partial resection of the tunica vaginalis, total resection of that membrane and inversion as practised by Doyen and which he considered the best.

COCAINE IN OPERATIONS.

At the Académie de Médecine, M. Reclus spoke on the use of cocaine as an anæsthetic for surgical operations which, he said, was not vulgarised for two reasons—first, on account of accidents observed by a certain number of dentists who omitted the precaution of making their patients lie down during their operations; and, on the other hand, surgeons were not familiar enough with the *technique opératoire*, which varied with each operation. He would indicate this procedure in cases of whitlow. First of all, the solution of cocaine should not exceed 1 or 1.5 per cent. An ordinary syringe was filled with the solution and injected at the base of the finger, under the healthy skin. The liquid was injected slowly, and the use of the knife should be stayed until the skin had become white. Once the operation terminated the patient should be kept in the horizontal position a short time and not allowed to leave the hospital before taking some food, or, what was better, a glass of brandy. By observing these directions no accident need be feared. He had operated thus over 7,000 times without the slightest trouble, and he proclaimed once more the superiority of that anæsthetic over chloroform and ether.

The above remarks elicited replies from several members who were unanimous in condemning the employment of cocaine.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 14th, 1903.

The *Deutsch. Med. Zeit.*, in its Carcinoma Supplement, January 19th, has a note on a

CASE OF CANCER OF THE STOMACH, WITH METASTASES IN THE INTESTINES AND PERITONEUM, WITH SPECIAL REFERENCE TO THE MODES OF EXTENSION.

A man, æt. 45, had suffered long from abdominal pain and diarrhœa, and toward the end of his life from ascites. At the autopsy was found cancer of the stomach with metastases in the mesentery, intestines and peritoneum. No gastric troubles had ever been noticed, and although a tumour almost the size of the fist was found situated on the greater curvature nothing had been known of it during life. The liver, lungs, kidneys, spleen, and pancreas were quite free from the disease; but, on the other hand, all the lymph glands of the abdominal cavity were affected. Further, there were large nodules over the whole course of the small intestine at the mesenteric attachment; these projected into the lumen of the bowel. The mucous membrane at these places was mostly intact, more rarely ulcerated. Microscopic examination showed these to be adenocarcinomata situated in the submucosa.

This curious situation of secondary carcinomatous growths had been noticed by Kraske and O. Israel, who had each seen a case. Both observers had offered an explanation of this curious mode of extension, to the effect that the lymph tract could not come into play for the disease in the regionary lymph glands; that

the nodules in the intestine had arisen through germs carried in the arterial tracts. The writer believes that the explanation would serve also for the case under notice. The disease of the lymph glands followed for the greater part from retrograde transport through the lymph channels, the parietal peritoneum was infected from the mesenteric glands. As regarded the nodules in the intestinal submucosa, the infection could not have been direct from the tumour in the stomach as the intestinal mucous membrane was almost intact, and the growths, without exception, were seated at the mesenteric attachment. Neither was the way improbable through the portal vein, the inferior vena cava and the heart, as the liver and lungs were quite free from disease. A direct passing through of disease from the original tumour into the mesenteric arteries must be assumed. He was able to make out microscopically the presence of disease in the lumen of the smaller arteries.

At the Society of Charité Physicians of the 22nd ult., Hr. v. Leyden gave an address on

THE ETIOLOGY OF LOCOMOTOR ATAXY.

He first of all reminded his hearers that since the first appearance of his book on this subject forty years had passed. As regarded syphilis as the cause of the disease, the standpoint of the adherents of this doctrine had not changed. As regards chill, the nature of which was difficult to define, dispute could not have any precision. The speaker then described two very important causes of the disease, viz., trauma and over-exertion. Regarding the first there were numerous cases known in which a "stumpfe" lesion of the nervous system started the symptom of the disease, at first at the site of the injury and later over the whole body. Experiments on animals, which Lehmann carried out on rabbits, showed the possibility of setting up the disease by injury of the spinal cord. Multiple sclerosis also, and, as recently shown by Stadelmann, late apoplexies, might be the results of trauma. Minow had shown also that slight injuries, for example small hæmorrhages, were able to set up the disease.

The second-named cause, over-exertion, had been considered by Romberg as a cause of the disease. Female sewing machinists, writers, and people of like occupations were most frequently represented. The causes named were of special importance from the point of view of the accident-laws. In conclusion, he showed a patient, a writer, on whom the first symptom of the disease appeared in the right arm, and also a method of proving the sensibility of the deeper parts, especially tone, by means of the tuning fork.

Hr. Senator said that as regarded the origin of tabes, the injury was the exciting cause, the disposition thereto being present before.

Hr. Kraus, in giving formal opinions was very careful, as frequently by further examination symptoms of the disease were found to have been present before the injury.

Hr. Schwechten remarked that in many cases a trauma would make a locomotor ataxy worse than it was before, and Hr. Schaper held that in such a case compensation would naturally follow.

Hr. Huber then spoke on

THE PROCESSES IN RECOVERY FROM PNEUMONIA.

In determining these processes, resolution must be distinguished from the crisis. The processes of the first-named autolysis had been studied or described by Friedrich Müller, the latter was not yet clear. The speaker showed that pneumonia grew differently in the serum of pneumonia from elsewhere. The processes of recovery appeared to him to be that first of all the body was made immune by the pneumococci in the blood. When there, so many immune bodies were

formed that positive chemotaxis took place, the pneumococci could no longer pass into the body, and then the crisis, autolysis, took place, and recovery set in. Phagocytosis could be seen in the sputum both during and after the crisis.

Hr. Menzer had shown that sera made from animal pathological streptococci were not so active as those from a human source.

Hr. Stürtz said that numerous experiments had shown him that as improvement began the virulence of the cocci diminished; in the very bad cases it was heightened.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 14th, 1903.

MIDWIVES AND ANTISEPSIS.

ACCORDING to law the midwife's outfit has become so extensive in order to guard against infection that the possibility of lightening her burden has been brought before the medical profession. It is pointed out that about forty sections are devoted to drugs and apparatus which the midwife is expected to carry about with her on every occasion, and to use at the proper time. A clear distinction is made between the use of instruments during pregnancy and those after labour. After defining the nature of the case to hold the instruments, the names of the various articles are stated, from soap, lanoline, vaseline, spirits of wine, tincture of cinnamon, permanganate of potash, irrigators, uterine tubes, rectal appliances with brushes for cleaning the tubes, catheters, nail scissors, nail brushes, a given quantity of lysol with measuring glasses, bath and body thermometers, bandages, towels, &c., and even comprise a text-book, the whole requiring a small ambulance van to convey a midwife to a confinement.

A medical genius has attempted to solve the difficulty of complying with the law by a case that will not exceed 4,750 grammes, or about six pounds, in weight. Such a trousseau is likely to meet with favour at the hands of the present over-loaded midwife.

HEPATIC TESTS, OR "DOCIMASIE HEPATIQUE."

At the Gesellschaft der Aerzte Seegen raised the question of the chemical tests applied by Lacassagne, of Lyons, as a diagnostic sign of the mode of death. From a medico-legal point of view, it may be sufficient for France, but he considers it quite inadequate for use in Austria, since he finds by experiment that the sugar found in the dead organ ranges between 0.4 and 4 per cent. His theory is founded on the presence of sugar and glycogen in the liver after death, which, he affirms, enables one to define the mode of death. If found in equal quantities, he designates the form "docimasie positive complete," which, according to his theory, indicates sudden death. The absence of these substances, on the other hand, or "docimasie négative," indicates a lingering death. If sugar alone be found and no glycogen, the inference to be deduced is that the individual had been ill for some time previously and had suddenly collapsed. This he designates "docimasie positive incomplete."

He looks upon the "agony" as a process of intoxication, and upon glycogen as an antitoxin. As long as the latter holds out death will not take place, but as soon as glycogen ceases to form the "agony" ends in death. He therefore concludes that the absence of glycogen is an indication, from a medico-legal point of view, that the person died suddenly. It is to his method of analysis that Seegen takes exception. His procedure con-

sists in taking a portion of the liver; this is washed free of all blood-clot, boiled, and the solution filtered. If glycogen be present the filtrate will have a milky appearance, if clear, glycogen is absent.

The sugar is found by Fehling's test. Seegen considers this test of glycogen to be far from accurate. He acknowledges the fact, however, that hepatic glycogen can be obtained after six or eight hours' boiling in a water-bath, decomposing with alkalis, and finally precipitating the albuminous matter by alcohol.

ADIPOSIS DOLOROSA.

Weiss showed a patient, *æt.* 43, suffering from adiposis dolorosa, which had commenced about nine months ago. Immediately after a few days' fever, a few swellings, about the size of a hazel-nut, painful to pressure, appeared on the right forearm. A month later others appeared on the left arm, chest, body, back, and legs.

The swellings were of different sizes, and varied in tenderness, but they made the patient's life miserable. Since their appearance the patient has been quite unfitted for work of any kind. The swellings are quite movable, and painful on pressure. There is no hereditary taint in the history, nor had the patient been previously ill except an attack of typhoid six years ago. He had, however, been addicted to alcohol prior to the appearance of the disease. Many of the lipomas were subcutaneous, but some of them were beneath the fascia. There was no symmetry in their arrangement, nor apparent connection with the trunks of nerves. The face, hands, and feet were free, and all the cerebral nerves were intact. The plexus brachialis and large nerves on the left upper extremity were very tender, while those on the right side were not. The sciatic nerve was normal.

The P.S.R. on the right side was more active than the left, and sensation was intact. There was no evidence of struma. The internal organs were normal, except for a slight increase in size of the spleen; and no abnormal changes to be found in the urine. Careful examination for glycosuria was negative. One of the tumours from the left arm was removed and examined. It was found to be a simple lipoma without any nervous connections, although in the immediate periphery of the tumour there was a large angiomatic increase of the blood-vessels.

In his remarks Schlessinger suggested that this angiomatic condition of the periphery afforded an explanation of the nature of the disease, and would also account for its rapid recession. As to the etiology of the pain he had himself pointed out that many of these lipomata were tender, while others were abortive, as was also evident from Weiss's case. Even in that case the sciatic was not involved nor tender, while the others in contact with nerves are very sensitive, and may be only approximately so in the periphery.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

EXTENSIVE OPERATION FOR MALIGNANT DISEASE OF LOWER JAW, PALATE, PILLAR OF FAUCES.—Mr. MAYO COLLIER operated on a man, *æt.* 55, the subject of extensive disease of the left lower jaw and adjacent parts. The patient was a healthy, fine individual, apparently enjoying the best of health, and but for what he called a bad tooth complained but little. Some six months ago a molar tooth had been extracted, and in the site on the alveolus a fungating mass had sprung up. Little notice was taken of this fact, it being looked upon as the sequel to the bad tooth. Some bleeding of the fungating mass had lately drawn the patient's

attention to the present condition of the part. On being admitted to the hospital, a fungating mass was found on the site of the last molar tooth on the left side. This had spread and involved the gums as far forwards as the first molar tooth. The anterior pillar of the fauces on this side was distinctly involved and some hardness was felt on the margin of the hard palate. The glands below the jaw were much involved. Mr. Collier said it was interesting to note how such extensive disease could exist without in the first place affecting the personal comfort of the individual and, later on, his health. It was fortunate that the patient had at this period applied for relief. A few weeks more would have rendered the case inoperable. As it was, a very extensive removal was contemplated as the only chance of prolonging the patient's life. This being consented to, an incision was made as for removal of the lower jaw as far forward as the canine tooth. This was extended into the angle of the mouth. Ample room was thus obtained for the removal of the parts, and adequate precautions were taken to deal with the hæmorrhage. The lower jaw was sawn through opposite the first bicuspid tooth and removed. The left side of the soft palate with the left pillar of the fauces was cut away with curved scissors. Part of the superior constrictor and the tonsils were also removed. The hæmorrhage was severe, but was arrested with little trouble. The glands in the neck were next attacked and removed. The parts were adjusted and the patient sent to bed with the face downwards. Mr. Collier said that, looking at this case at first examination, one hardly contemplated such an extensive operation, but seeing how far the disease had superficially invaded the palate and fauces nothing but an extensive operation held out any prospect of success. He said that until quite recently he had refused to operate on these cases, the prospects of partial success being so remote, but his recent experience with several cases of extensive disease in and about the fauces had taught him that not only was the disease removable, but the life of the patient was prolonged in comparative comfort. Several of his cases recently reported, he pointed out, to all intents and purposes were well, and some of them were following their ordinary occupations. The risks, during the operation, he remarked, if adequate precautions are taken, were very slight; the complications of the after treatment were reduced to a minimum by retaining the patient in a prone and recumbent position, thereby securing natural and effective drainage. He considered it quite astonishing the wonderful recuperative powers of the patients about the pharynx, a week or ten days sufficing to complete the healing after the most serious operation.

Ten days after the operation the patient left the hospital with the parts healed and sound.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

OPERATION FOR CONICAL CORNEA WITH THE GALVANO-CAUTERY.—Mr. WORK DODD operated on a girl, *æt.* 19, who had been admitted into hospital for double conical cornea. Before operating, Mr. Dodd drew attention to the fact that the normal cornea is nearly circular in shape, and that its arc extends for about one-sixth of the circumference of the globe and that it has a smaller radius of curvature than that of the sclerotic; this makes its rounded surface appear to project more sharply than the line of the sclera. The average horizontal diameter of the normal cornea, he said, is about eleven millimètres. In this case of conical cornea, or kerato-conus, he said, it would be observed that instead of the usual bluntish curve of the cornea

there was a sharp cone beyond the normal curvature; this condition, he pointed out, was generally seen in women (Mr. Dodd had never himself seen it in a man), and is not uncommon. It seems to come from some progressive asthenic condition of the health. It would also be observed that the centre of the cone looked thin, possibly it was this thinning which caused the cornea to give way before the intra-ocular tension. Slight cases of the trouble, he pointed out, are not easy of diagnosis, and some cases of irregular astigmatism were undoubtedly early conical corneæ. In the well-marked cases the naked eye, assisted by oblique illumination, was all that was needed for accurate diagnosis. No form of glass, as a rule, improves the vision of these cases, and as this last is usually very defective, he thought operation, with the intention of causing the cone to disappear, was at present the only treatment which held out any hope of a good result. Various operations, he said, have been suggested for the relief of this condition, such as (1) cutting off a small superficial flap of the cone and subsequently cauterising the denuded surface; (2) repeated paracentesis to let out the contents of the anterior chamber to lessen the intra-ocular tension; (3) removing a small disc from the apex of the cone with a specially made trephine; also (4) the excision of an oval piece of the cornea (an operation which Mr. Cowell generally adopted); finally (5), the application of the galvano-cautery to produce the desired loss of material, which last has been regarded of late years perhaps as the most favourable procedure. It should be observed, he said, that in all the operations where loss of substance in the centre of the cone takes place a thick nebula or scar must result, and so the central vision must necessarily be much affected; this has been remedied as far as possible by doing an iridectomy for visual purposes, generally downwards and inwards to allow the patient to see, as it were, round the scar. Critchett's method of operation, Mr. Dodd pointed out, was to apply the cautery to the centre of the cornea until almost a concave depression was formed, taking care not to perforate into the anterior chamber; the results of this operation in his hands has been sufficiently good to cause surgeons to follow his lead. Mr. Dodd himself had done several cases, using a modified method of the same operation so as to avoid the subsequent iridectomy downwards and inwards. He then proceeded to apply the cautery in the present case, his method of operating being as follows:—A small galvano-cautery is applied in a series of dots situated about a millimetre apart, so as to form a horse-shoe shape around the cone in order to leave the centre of the cone free and also that portion of the cornea untouched which is usually occupied by the iridectomy downwards and inwards. The cautery, he remarked, must be applied so as to burn deeply, but, of course, without perforation. The eye was then dressed with vaseline and bandaged. Mr. Dodd said that the operation would probably have to be repeated at intervals to fill up the inter-spaces and to get sufficient contraction.

Mortality of Foreign Cities.

THE following is the official weekly return of the rates of mortality in certain Indian and foreign cities:—Calcutta (including suburbs) 40·4, Bombay 72·2, Madras 32·5, Paris 19·7, Brussels 18·1, Antwerp 17·8, Amsterdam 15·1, Copenhagen 17·3, Stockholm 12·6, Christiania 19·7, St. Petersburg 26·3, Moscow 25·5, Hamburg 17·6, Munich 21·5, Vienna 21·1, Prague 26·9, Buda-Pesth 22·4, Rome 20·0, Cairo 26·6, Alexandria 30·6, New York 19·7, Philadelphia 20·1, Boston 20·3.

REGISTERED FOR TRANSMISSION ABROAD.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, FEBRUARY 18, 1903.

THE HYGIENE OF LONDON LOCOMOTION.

FACILITIES for speedy locomotion are essential for useful and happy life in London and other populous cities. Recent years have brought much change in methods of travel. Modern innovations are influencing the Metropolis in a way which even the most daring speculators in the days of our fathers had not dreamed of. The introduction of electric traction has simply revolutionised our methods of locomotion. London is becoming under-tubed, and with shallow sub-way trams and overhead railways, motor omnibuses, and private automobiles dashing along in all directions we only need the coming of the air-ship to complete and fill up the measure of the City's perplexities. We are therefore glad to find that his Majesty has appointed a Royal Commission to inquire into the means of locomotion and transport in London. Report is to be made as to the measures deemed most effectual for the improvement of the same by the development and inter-communication of railways and tramways on or below the surface, by increasing the facilities for other forms of mechanical locomotion, by better provision for the organisation and regulation of vehicular and pedestrian traffic. The members of the Commission have also to consider the desirability of establishing some authority or tribunal to which all schemes of railway or tramway construction of a local character should be referred, and the powers which it would be desirable to confer upon such a body. The members of the Commission are, generally speaking, well chosen, but we are disappointed to find that the medical and hygienic aspects of the subject have apparently not been considered of sufficient importance to necessitate the appointment of a medical expert as one of the Commissioners. And yet the sanitary point is one of the utmost

importance to the nation. Dr. Louis C. Parkes, in the current number of the *Practitioner*, deals with the question of London locomotion in its health aspects, which speculators and passengers are only too apt to neglect. It seems clear that the problems connected with the demolition of slums and insanitary areas, the better housing of the working classes, the prosperity of trade and the flourishing of business necessitate much improvement in the means for bringing the centre into intimate connection with the suburbs and facilities where rapid transit may be allowed from one district to another. At present we seem far from securing any such scheme, and not a few of the means now available for travel are altogether free from serious risk to health. The popular "tube" of the Central London Railway has an atmosphere containing 15 to 20 parts per 10,000 of CO₂, which, being derived solely from a human source, and hence necessarily associated with many deleterious organic impurities, cannot but eventually prove injurious to health. The air also being constantly in movement facilitates the ready dissemination of infective material in the form of fine dust. We are astonished at the laxity of the company's officials in allowing expectoration, which makes many lifts simply disgusting. A bye-law should make spitting an offence punishable by fine. At present no satisfactory means are provided for the renewal of the air, although we understand a system of ventilation by exhaust fans is about to be introduced. On the grounds of health, overcrowding of carriages beyond their seating capacity should be absolutely prohibited, and it is much to be desired that in the future there may be an extension in facilities for rapid transit by what we may term "open-air" service or by "day-light" routes, and that enterprising man will be less anxious to undermine his health by undermining his city. Horse traction, it is clear, must quickly give way to mechanical methods. We are avowedly in a state of transition. But amidst all the tangle of ill-digested schemes which daily perturb the traveller and worry the financier, we contend that hygienic considerations should have first place.

RECENT TEMPERANCE MOVEMENTS.

THE terrible evils arising from the abuse of alcohol appear to have at length aroused the sluggish conscience of the people of the United Kingdom. Of late there have been various determined efforts, both social and legislative, to restrict the dangerous influences that beset the drink traffic. For many years temperance workers have laboured to obtain results that now appear to have fallen at their feet with the startling suddenness of a bolt from the blue. Mr. Balfour's Government has been not inaptly described as one of surprises, and in the present instance the term certainly seems appropriate. As a medical journal we are not in the least concerned with the political aspects of the case, although it is impossible to blink the fact that they are of a far-reaching and weighty kind. Suffice it to say that the new Acts, while for the most part avoiding the new paths advocated by the temperance party, have nevertheless

produced the most stringent and radical measure ever yet passed with regard to this particular subject. The powers of the police and of the magistrates have been greatly increased, and drunkenness is now in itself an offence. The scandal of the chronic drunkard of the police-courts has been met by the publication of "black lists" of persons convicted of drunkenness more than a certain number of times within the year, and by giving powers of compulsory detention of such inebriates for any period up to three years. The personal responsibility of the publican and of his servants in the serving either of already intoxicated customers or of persons on the official black list is stringently enforced. The control of the police over crime is greatly increased, inasmuch as drink and crime are closely associated, and to control the one is to a great extent the same thing as preventing the other. In these ways, not to mention others, much good may be anticipated from the new Acts. The individual citizen may be expected to realise the increased disadvantages and disabilities attached to drunkenness. Indirectly the public gain by the diminution of crime by the reduction of drunkenness, and by the greater control they have acquired over license-holders, and therefore of licenses. The future working of the latest Act, therefore, will be awaited with a considerable amount of interest by the medical profession, who are deeply and closely interested in the preventive as well as in the wider aspects of alcoholism. Apart from the legislative treatment of the problem there is the important question of the administrative limitation of licenses. A remarkable tendency to curtail the excessive local distribution of licenses has been recently shown by magistrates in all parts of the country. A typical instance is that of Romford, Essex, where a large firm of brewers was refused a retail license at their brewery, within two hundred yards of which were nine fully-licensed houses and two grocers with off-licenses. The latest temperance organisation, if so it may be called, has been dignified with the contradictory and ridiculous name of semi-teetotalism. How a man can be a half of a drinker and a whole teetotaler at the same time is more than a mystery. The meaning of the new guild, however, is fortunately less obscure, inasmuch as it pledges its members to strict moderation in the use of alcohol. In these various ways the cause of temperance has doubtless received a vast stimulus, which may to some extent be gauged by the indignation and alarm displayed in those journals which are entitled to express the opinions of the "trade" that is directly concerned.

THE VICEROY AND THE MEDICAL PROFESSION.

THE pointed and graceful compliment his Excellency the Lord Lieutenant paid to medicine at the annual dinner of the Royal College of Surgeons in Ireland, "To Irish surgery I owe Lady Dudley's life. How, therefore, is it possible for me to feel too great a gratitude, or too much honour to your noble profession and your college?" is the

compliment of a grateful and appreciative heart, the natural speech of one who has had a great delivery—a delivery secured by skill and care. And his Excellency fully recognised that safety was the outcome of skill and experience. "How fatal would have been the result had there been an indiscretion, delay, or hesitation in performing the operation, difficult and critical as it was from the violent character of the attack." Having paid this deserved compliment to the distinguished surgeon who performed the operation, and through him to medicine, his Excellency passed from the subject of medicine to speak of the land question and the new Agricultural Department. He seems in the midst of medical practitioners to have forgotten the numerous, intelligent, and hard-worked union medical officers, who in all weathers, by night and by day, throughout the length and breadth of the land, are going from house to house on the same errand of mercy that he so fully and so heartily recognised when paid to his own hearth. The opportunity of speaking a word of hope to the thousands of Poor-law medical officers was lost, and once more the reasonable expectations of a large body of underpaid medical officers is disappointed. We incline to the opinion that the omission of any reference to the existing discontent with the Poor-law medical service was an oversight, probably caused by the importance a politician would attach to the impending Land Bill. Unfortunately the politician considers every interest according to its influence at the ballot-box, and the scattered union medical officers cannot turn the scale of a contested election in any Parliamentary division in the country. As electors they are feeble folk. But their strength lies in their union and hearty co-operation for common ends. Better pay, a yearly holiday, and a pension are the minimum changes necessary, and until these are secured the Poor-law medical service should find no candidates for its appointments. There are at present many openings for young men, both in the Colonies and at home, so that they are not deprived of employment by avoiding the drudgery of dispensary appointments. By patient waiting the *non possumus* of the Irish Local Government Board will be quietly overcome, and with a sense of self-respect and a recognition of their great worth, both by the department and the public, members of the medical profession will gladly once more associate themselves with union work in the country.

Notes on Current Topics.

The Topical Treatment of Disease.

M. BOUCHARD has brought to a close his series of interesting papers on the advantage of the topical application of medicine in contradistinction to their general internal administration. With much that the distinguished savant says we find ourselves in complete harmony, and he strengthens his case with many illustrative cases drawn from his own practice. And yet his arguments are not wholly convincing; in medicine, as in every other science,

we must bear in mind that truth is many-sided. We think that in practice the physician will be most successful who adopts both the general and topical medication, not in accordance with any hard and fast rule, but from due consideration of the peculiarities of the patient. We cannot, if we would, get away from Sydenham's axiom, "treat the patient"; and as Abernethy, in his classic work on local diseases long since told the profession, there are local lesions that demand general treatment. At the same time, we think that in drawing attention to the benefit derived from the local application of light to lupus ulcers and the good effects of mercury when applied to or injected in syphilitic sores, and the effects of local treatment in ophthalmic treatment, M. Bouchard has done a service to his professional brethren. The trend of medicine is in the direction he points; the surgeon operates in cases of peritonitis, and does not hesitate to trephine for and open cerebral abscesses, and the physician makes aseptic the alimentary canal, or at least tries to antagonise sepsis by antiseptics, and the hypodermic needle is used in sciatic pain, and the pericardium aspirated. But all said and done there is still a large residuum of patients who call for general medication. We still find the anæmic girl demanding fresh air, good food, and tonics, the martyr to constipation and the neurasthenic. The difficulty is in preserving an open mind in medicine and avoiding grooves of thought, each line of treatment has its use, and in its proper adaptation of a means to an end the accomplished physician is revealed.

An Unusual Sequela of Appendicitis.

AN argument in favour of the early operative treatment of appendicitis may be deduced from a very interesting case brought before the Medical Society of Nuremberg by Dr. Charles Koch. A labourer, forty years of age, sustained a blow on the belly in April, 1901; appendicitis followed, and was treated medically, and the patient made a good recovery. Fifteen months afterwards, August, 1902, he got a slight chill, and twelve days later a marked rigor, with bilious vomiting and an intermittent type of fever with frequent rigors. This condition lasted six weeks before Dr. Koch saw the patient. The physical signs and symptoms all pointed to an hepatic abscess, and a laparotomy was performed, and the viscus made adherent to the incision. That night the patient died. On examination of the body the vermiform appendix was found to be gangrenous and encysted in a large abscess, and the right lobe of the liver was almost wholly occupied by a collection of pus; the left lobe had an abscess about the size of a nut. Humanly speaking, this patient might have been saved by excision of the vermiform appendix, and as the other viscera were found healthy it is a reasonable inference that the purulent inflammation of the appendix was the exciting cause of the hepatic abscess. It is, however, easy to be wise after the event, and such wisdom availeth naught nevertheless we must

from such cases be warned that in leaving a devitalised appendix in the abdomen we are running great risks of dangerous sequelæ.

Railway Risks.

THE loss of life due to a train in the United States consequent upon accidental damage to the oil tank, draws attention to the risk of life incidental to railway travelling, especially in American vestibule cars. We refer to this because corridor cars and vestibule ones are becoming common on British and Irish railways, and these are possessed of so many elements of comfort and convenience that the public demand them. The old carriage, with its side doors, made on the model of the old stage coach, had many inconveniences; but it had the advantage of offering many doors of egress. But in a vestibule carriage or in a long corridor with a single door of exit, there is no possibility of other than the merest percentage to escape. This dreadful risk might be avoided by fitting the sides of all long vestibule cars with sliding panels. Such panels would add to the cost of production, it is true, and the railway companies would naturally be inclined to resist the demand; but an extra expense when necessary for the public safety cannot be considered. Thanks to the improved modes of working and the mechanical appliances which have been adopted to secure the safety of the travelling public, the loss of life on British railways is comparatively small. The number of personal accidents to passengers, railway servants, and others reported to the Board of Trade during the year 1901 show a total of 1,277 killed and 18,578 injured out of 1,174,275,036 passengers and about 150,000 railway servants.

Hernia in the Very Young.

WE are so much accustomed to consider the crying of very young children as either a call for food or a cry of pain from flatulent distension of the alimentary canal, that occasionally we overlook some serious trouble. Children are so helpless in sickness that none but a mother's ear can detect the slight modification in the cry that tells of pain or calls for food. We therefore should satisfy ourselves by examination of the child in every case when the mother brings her baby for advice. The value of this systematic examination of the baby and the necessity for it, is pointedly shown in a case of Dr. N. Gomez Rozas, who met with a case of strangulated right inguinal hernia in a child thirty-one days old. He operated on the boy in the Municipal Hospital, Haracecia. He found the hernia to contain the end of the ileum, the vermiform appendix, and the cæcum coli. The appendix was excised, the hernia reduced, and M. Championnière's radical operation performed. Of course, such cases are unusual, but it is just the unusual cases which may make the reputation of the beginner who systematically examines each patient, or damns the reputation of the senior who has ceased to worry about unusual causes. But quite apart from professional advantage from the habit of a careful study of each case, it is

to the patient that the cause of the illness be carefully sought out and not hurriedly diagnosed.

Experience of Drowning.

VERY few people who have had the experience of being partially asphyxiated by drowning take the trouble to preserve a record of their sensations during the time. Naturally but few are competent to note the facts with any coolness, and therefore the publication of a complete narrative of his experience in such circumstances by a medical man is peculiarly interesting. Indeed, we have not for a considerable time read anything more dramatic and life-like than the paper by Dr. Lowson on this topic in the December number of the *Edinburgh Medical Journal*. Death by drowning has usually been described as a painless and even a pleasant one, but Dr. Lowson is able to contradict this. In the early stage the most striking thing was intense, intolerable pain in the chest; "it seemed as if one were in a vice, which was gradually being screwed up tight, until it felt as if the sternum and spinal column must break." At this point the author had time to reflect on how far wrong his old teacher, Sir Henry Littlejohn, had been when describing death by drowning as being as pleasant as "falling about in beautiful green fields in summer." Gradually, however, after several abortive gulping efforts to inspire, as the carbonic acid in the blood began to increase, the pain began to lessen, and the mental condition became that of one in a pleasant dream. And like a vivid dream the author still retains memory of the clearness with which his view of the native "hills at home" flashed across his mind. Before consciousness disappeared the sensations were positively pleasant. Dr. Lowson does not think that while consciousness lasts, it is possible for any water to enter the trachea or lungs, though a good deal is swallowed.

An Early Sign of Scarlet Fever.

IN view of the obligation imposed upon practitioners to diagnose certain infectious diseases, scarlet fever among the number, even in the absence of the fully developed prodroma, every minor sign which is likely to assist in an accurate diagnosis is of value. According to Dr. McCollom, of the Boston City Hospital, great importance attaches to the altered appearance of the fungiform papillæ of the tongue. Early in the attack, long before the appearance of the classic symptoms, close inspection of the tongue reveals well-marked hypertrophy of these papillæ, which, in some cases, resemble small nodules of Cayenne pepper, while in others they are merely little pimples without any distinct reddening. The "strawberry tongue" is only a later development of this inflammatory hypertrophy, which first manifests itself in the fungiform papillæ. It is the first characteristic sign to appear, and it does not subside for at least five weeks. A somewhat similar hypertrophy is met with in certain other exanthemata, notably in measles, but in such case the hypertrophy is less

pronounced and the distinctive coloration is not observed. Incidentally, Dr. McCollom calls attention to a retrospective sign of scarlet fever which may prove useful in cases in which the disease has not been diagnosed at its onset, viz., a white line which makes its appearance on the nail close to the bed, coincidently with the commencement of desquamation, that is to say, at about the fifth day of the malady. Even when desquamation is but slight, consequent upon an ill-developed eruption, this white line is always present.

Pneumonia and Tuberculosis.

It is some years since attention was called to the fact that while the death-rate from tuberculosis showed a tendency to diminish, that from acute pneumonia, on the contrary, was increasing. This, it seems, holds good in the United States, for in the recently-issued report of the Health Department of Chicago the deaths from pneumonia are shown to account for one-eighth of the total mortality, that is to say, one-third more than phthisis, and 46 per cent. more than all the other infectious diseases combined. *Pari passu*, the statistical returns demonstrate a similar condition of things throughout the country as a whole, a decrease since 1880 of 20.7 per cent. in the deaths from phthisis offering a striking contrast with an increase of 7.4 per cent. in deaths from pneumonia. No plausible explanation of this shifting of the incidence of mortality is forthcoming, but the matter is obviously one worthy of attention. Of course, in many instances pneumonia is merely the manifestation of vital exhaustion, an indication that the circulation is bankrupt and that the organism can no longer be maintained as "a going concern." It is, indeed, highly probable that under the term pneumonia are included many modes of death characterised by acute pulmonary congestion, which is due, it may be, to circulatory failure consequent upon renal disease or sheer exhaustion, quite apart from any microbial invasion. For statistical and educational purposes it is highly desirable that a more accurate etiological diagnosis should be arrived at. We are only concerned with the classic sthenic form of the disease associated with the presence of a specific micro-organism for the others, being merely modes of dying, are not amenable to remedial measures or at any rate to a much more limited extent.

The Salicylates in Acute Rheumatism.

ALTHOUGH the salicylates are not a specific for rheumatism in the sense that quinine is in regard to malaria, they exert a well-marked influence on the general symptom-complex known as acute rheumatism, so marked indeed that it is permissible to consider that influence as a therapeutic test for true rheumatism. Cases, therefore, that are not favourably influenced by their administration may be suspected to be dependent on some other etiological factor than that of simple acute rheumatism. To obtain the characteristic effects of the salicylates in acute rheumatism, however, it is necessary to administer the drug in doses of not less

than a hundred grains daily, to be maintained during the continuance of the acute symptoms. The value of the treatment is greatly influenced by the tolerance of the patient, for the drug is not always well borne. It is very apt to disturb digestion, already seriously impaired by the disease, and in patients with already over-burdened kidneys the elimination of the drug is apt to be attended by unequivocal symptoms of congestion; in fact, it is well to make a routine practice of investigating the condition of the kidneys before pushing the remedy. Moreover, certain patients, especially the young, exhibit a peculiar susceptibility to the action of the drug on the nervous system, a mild form of delirium following the ingestion of even moderate doses, or the disturbance may take the form of salicylic dyspnoea, an alarming if not very serious manifestation. The allegation that the employment of the salicylates renders the sufferers more prone to cardiac complications is only true in so far that the relief which the treatment affords to the painful manifestations tempts the patient to premature exertion, thus throwing a strain upon the heart which it is not as yet in a state to resist. The analgesic action of the salicylates, moreover, must not blind us to the importance of combating the disease simultaneously by the administration of alkalis which unquestionably favourably influence the progress of the disease.

The Prophylaxis of Baldness.

THE view that baldness is essentially due to the depilatory action of certain bacteria appears to be gaining ground. Hitherto it has been the generally received view that baldness is of the nature of an inherited predisposition, and it is a matter of everyday observation that the members of certain families are more prone to premature calvities than others. This, however, holds good in respect of almost every disease, consumption, for instance, although the latter has long since been conclusively proved to be a transmissible, and therefore a preventible, disease. The fact that baldness is usually associated with the presence of certain bacteria hardly suffices to prove the accuracy of the deduction, for these may be merely the accidental accompaniments of a depreciation of local vitality. However produced, it can hardly be doubted that the neglect of hygienic precautions has a definite influence in determining the premature loss of hair, hence the imperative necessity for greater attention to surgical cleanliness in respect of instruments and appliances used to the scalp. It may be urged that in parts of the body which receive less attention than does the scalp baldness is quite the exception, but these parts are also less exposed to infection from without so that the argument fails. No doubt a number of factors conduce to the premature shedding of an appendage which is sometimes ornamental and always useful, and if any progress is to be effected in the prophylaxis of baldness we must carefully avoid concentrating our attention upon any one factor to the exclusion of the others.

A Curious Case of Persistent Amenorrhœa.

A CURIOUS case of amenorrhœa of sudden onset was related by Dr. John Knott at a recent meeting of the Irish Academy of Medicine, and it is interesting as evidence of the fact that cessation of the menstrual flow is not inconsistent with perfect health, a view which is by no means popular among women, nor even among gynæcologists. The patient, a robust young woman, previously quite regular, had contracted typhoid fever some years before, when she was treated by the refrigerant method, which had the effect of arresting the menses then in progress. She recovered completely from the illness, but has never since had any return of the flow, a circumstance which does not appear to have in any way influenced her general health prejudicially, although not even a trace of the menstrual molimina remained to recall the abolished function. It is common knowledge that the greatest variations obtain in respect of menstruation, not only as to the age at which it is inaugurated, but also as to its termination. Nay, more, even during the period of menstrual activity, some women are habitually irregular, in respect of both time and quantity. Its abrupt cessation while still in full swing is, however, a very unusual event.

The Treatment of Idiopathic Epilepsy by Bromides.

THE recent discussion at the Medical Society of London on the treatment of epilepsy cannot be said to have indicated much advance in the control of this mysterious and distressing group-symptom, at least by medical measures. Most physicians still contend that bromides are of conspicuous service, but Dr. Aldren Turner from analysis of the records of the Queen's Square National Hospital for the Paralyzed and Epileptic shows that the percentage of actual "cures" cannot be considered greater than in pre-bromide days. But even if bromide does not succeed in permanently arresting the convulsive seizures it certainly affords such relief as in many instances at least permits of the minimum of limitation in life's duties and pleasures. There would seem, however, to be need of much greater care and attention in the administration of bromide preparations than is generally given. Most epileptics have to be treated at home, seen merely as out-patients, and but few can be studied in hospital or a suitable institution, and hence opportunities for constant and continuous observation are not afforded, and unfortunately also the effects of bromides cannot usually be watched with the care and precision desirable for scientific investigation. Hence opinions as to the service rendered by bromides vary greatly. Some speak of the prejudicial mental and physical effects following its long continued administration; while others deny any such occurrence, and bring forward cases in which bromides have been continuously taken and have been necessary for the restraining of the fits over periods of many years. Not a few physicians prefer to alternate the various bromides, many always keep to the potassium salt,

others consider ammonium bromide the least depressing, and still others always give it freely diluted with alkaline waters, or in association with arsenic. And of recent years there has been no lack of those seeking for some new bromine preparations, and hence the introduction of bromide in oil of sesame or bromopin, and the like. Much difference of opinion also exists as to the dose, the time and frequency of administration. There are also certain patients that receive no benefit from bromides, and, indeed, according to some observers, are rendered worse. With too many it seems the custom to give bromides and neglect important adjuncts and desirable accessories of good hygiene, sound simple diet, tonics, baths, massage, and electricity, and judicious discipline with open-air life. It is also interesting to note that salt starvation is considered by many a useful adjuvant to bromide treatment. It would be well if we could secure sounder principles for the administration of bromide before discarding it for the empirical use of such bodies as borax, nitro-glycerine, zinc, cannabis indica, belladonna, chloral, camphor and the many others vaguely advised.

Inquiry into the Treatment of Eclampsia.

WE are requested to make it known that the Clinical Society of Manchester has undertaken the task of inquiring into the most successful methods of dealing with puerperal eclampsia. For the purpose of this inquiry all practitioners who have been called upon to attend women suffering from this disease are requested to communicate notes of the cases to the Chairman of the Committee, Dr. J. Price Williams, Swinton, near Manchester, who will forward a form of report along with a letter explaining the object and scope of the investigation. When completed, the reports will be published in a suitable form for reference, and it is hoped that information of value to the profession will thereby be afforded.

The Ventilation of Tube Railways.

THE more the subject of the atmospheric conditions of deep tube railways is investigated the less satisfactory do they appear. The recently published report of the Public Health Committee of the London County Council demonstrates with what rapidity the air becomes contaminated by the emanations of the thousands of passengers who are willing to risk health in exchange for convenience and promptness of transport. Roughly speaking, 78 p.c. of the samples of air taken for analysis proved to contain twice as much carbonic acid as the outside air and 66 per cent. between two and three times as much. The gravity of the fact is aggravated by the circumstance that while the proportion of carbonic acid affords the readiest way of gauging the impurity of a given sample of air, taken alone it affords quite untrustworthy indications of the injurious effects of such air. We note, for instance, that the air in the Metropolitan Railway between certain stations contained a proportion of carbonic acid far in excess of the figures just given but much of this is accounted for by the products of com-

bustion given off by the locomotive, whereas in the tube railways it is merely an indication of the proportion of respiratory impurities, the toxic action whereof is due to the organic emanations associated therewith. This factor will have to be borne in mind in discussing the desirability of further development of this system of transport!

When Doctors Differ—Judges Decide.

THE active campaign against the abuse of alcoholic beverages which is at present on foot in France promises to give rise to a curious situation. The Prefect has placarded the walls of Paris with strongly worded warnings against the use of certain pernicious beverages—absinthe and the various bitters among the number; the manufacturers thereof feel aggrieved and propose to "have the law" against their traducers. Incidentally, the question will have to be settled whether alcohol is in any sense a food, a view which has recently secured an influential recruit in the person of Dr. Duclaux of the Pasteur Institute. Now opinions are greatly divided in regard to this question, and it looks as if the judges, aided possibly by a jury, will shortly be called upon to decide the vexed question once and for all. It would effect an enormous saving of time if many other disputed points could be adjudicated upon in like manner. As it is, they crop up again and again at learned societies and in the journals, without, so far as one can judge, achieving any progress towards a definite solution. It must be conceded that a verdict in favour of alcohol being a food would not make it one, or if really a food a desirable one. If, however, to decry the use of alcohol can, by any legal chicanery, be constructed to constitute a libel on distillers, it behoves us to be careful, for all the best counsel procurable would be found under the banner of intemperance, attracted thither by the limitless fees at the disposal of those who batten on the vice and misery of the people.

Stage Doctors and Nurses.

"To see ourselves as others see us" is an experience in many ways to be desired from a disciplinary point of view. In a clever and amusing play recently produced at a London theatre under the title of "A Snug Little Kingdom," a burlesque type of fashionable young physician plays a leading part. He has discovered a new disease of apparently well-nigh universal distribution, which he at once detects in a millionaire patient whom he has secured by the fortunate chance of saving him from being run over in a crowded street. The millionaire pays his young medical adviser two guineas daily for advice as to the new disease, but he explains to another person that for all important symptoms he calls in the far older and more experienced physician, "Sir Umphry." On the whole we think the public will not gain much from the burlesque treatment of a profession with whose merits and demerits they have had of necessity a life-long acquaintance. Harley Street is spoken of in the play as "The valley of the shadow," and a gentleman who has just taken a high standard

medical degree displays the general attributes of a weak-witted fool. The nurse of the play is represented as a heartless, designing, grasping, snobbish, and incompetent adventuress. That there are undesirable types, both of medical men and of nurses, may be freely admitted; but we venture to think that the creative faculty must be defective in the artist who is compelled to fall back upon grotesque abnormalities when he seeks to tell his story in dramatic form.

London Lunatics and Fire Risks.

THE recent fire at Colney Hatch should serve as a warning not only to every lunatic asylum authority but to every hospital committee in the United Kingdom. The disastrous fire which claimed fifty-one victims occurred in a temporary structure, but sooner or later it is to be feared that a fire will break out in a large permanent asylum with consequences that will shock the world. The plain English of the case is that, from a structural point of view, there is, as a rule, little or no attempt to guard against fire, while closely locked doors naturally form an essential feature of the asylum system. If any building in the world should be fireproof, or perhaps it would be better to say "fire-resisting," that place should surely be an asylum or other institution devoted to the cure of sick and disabled persons. It is to be hoped that the London County Council will take the lesson of the Colney Hatch holocaust to heart, seeing that they have more than 16,000 lunatics under their care. There are temporary structures of wood and iron at Hanwell, and also at Horton Manor, and for all we know at other asylums of the County Council. How long are these temporary structures to remain? For many years past we have urged in the columns of THE MEDICAL PRESS AND CIRCULAR that the public should insist on proper construction of hospitals with a view to fire prevention. Otherwise the disaster of Colney Hatch to-day will be the tragedy of some great hospital to-morrow.

Gynæcological Nursing.

It has long been felt by the profession that there exists no reliable criterion by which the efficiency of nurses, especially those who undertake gynæcological work, can be tested. Certificates delivered by lying-in hospitals do not infer an adequate standard of technical training in the domain of gynæcology, indeed, no trustworthy evidence is available, so that the practitioner is fain to take the nurse at her own valuation. This lapsus the British Gynæcological Society has undertaken to remedy, and in his presidential address to the British Gynæcological Society, Dr. Heywood Smith was enabled to outline a scheme for the institution of examinations and the grant of certificates of proficiency in monthly and gynæcological nursing. The chief feature of the scheme is that no person will be eligible as a candidate unless she has had three years' previous training in hospital work, already a serious guarantee of general training. The objections which have been urged in certain quarters to special "diplomas" do not apply here,

since it is specifically stated that the certificates apply exclusively to nursing. We see no objection whatever to nurses obtaining certificates of special aptitudes, especially when such certificates are accorded after examination by responsible bodies; indeed, the plan is one which might with advantage be extended to other departments, since it is all important in special cases to have nurses duly trained to the particular duties which they are called upon to discharge. We congratulate the society on this new departure and do not doubt that it will be attended by happy results.

The Chair of Anatomy at Edinburgh.

THE Curators of Patronage of Edinburgh University have made the appointment that was expected in choosing a successor to Sir William Turner, and have undoubtedly done well for the University in inducing Professor Cunningham to return to his *alma mater*. Possessed of indefatigable energy and immense administrative power, no man is more capable of managing an important department, while his acknowledged eminence as an anatomist and man of science well maintain the dignity inseparable from the chair of the Monros and Goodris. And Dr. Cunningham's return to Edinburgh means no revolution in the splendid traditions of the anatomical department there, for it will be remembered that, himself a pupil of Sir William Turner, he was also one of his demonstrators for no less than eight years. In 1882 he was offered the Chair of Anatomy in the School of the Royal College of Surgeons in Ireland, and in the following year he moved to the similar chair in Dublin University in succession to Professor Alexander Macalister. His principal publications are a "Manual of Practical Anatomy," in general use in most dissecting rooms, and a "Treatise on Systematic Anatomy," which only appeared a few months ago; but Dr. Cunningham is well known for his frequent communications to the scientific journals. In addition to many honorary degrees he is a Fellow of the Royal Societies of London and Edinburgh. His removal from Dublin leaves a great blank not only in the University but in the city. He has long been one of the most active members both of the Royal Dublin Society and of the Royal Irish Academy, and it is only a few days since, after many years' secretaryship, he accepted the Presidency of the Royal Zoological Society.

The Surgical Treatment of Suppurative Affections of the Knee-Joint.

ALTHOUGH surgeons have of late obtained a much firmer grip of the treatment of acute suppurative inflammations of the knee-joint, there is still a curious diversity of opinion in reference to the extent and details of the operative procedure. Some surgeons practise free incision, flushing the interior of the joint with antiseptic solutions, while others, apparently in the same class of cases, content themselves with small incisions at the inner side of the patella and washing out with saline solution. Excellent results are claimed for both procedures, and this amounts to a verdict in favour

of the latter, since *ceteris paribus* the less the local disturbance the better the prospect of obtaining the great desideratum, a movable joint. The most dangerous cases are those in which septic inflammation occurs as the consequence of wounds of the joint or after wiring the fractured patella. In these, very drastic measures are often called for, and in such severe cases drainage of the joint through the posterior synovial pouches has been advocated, a procedure not unattended by considerable risk of damaging the structures situated immediately behind and external to the joint.

Recent Aspects of "Christian Science."

WE came across a letter in a Canadian contemporary from a believer in "Christian Science," stating that the death-rate among the adherents of the principal "Christian Science" church in Boston was only half that of the general population. We have no reason to doubt the accuracy of this statement, since we are sure that few Eddyites remain true to death, and consequently defections from the fold can always be assigned to other causes. It is some satisfaction that the Eddyites are gradually diminishing the field of pathology which (though, of course, to the non-existent) they claim as their own. Some time ago we learned that as a concession to popular prejudice they had declared that it was permissible to obtain the aid of a surgeon in purely surgical disorders. And now another backward step has been made. A child recently died of diphtheria in the State of New York, having received no medical care, but being subjected to Eddyite rites and formulæ. Luckily such a public outcry has been raised that the Eddyites find it necessary to retract their ground, for their high priestess herself has promulgated a decree that "until the public thought becomes better acquainted with Christian Science the Christian Scientists shall decline to *doctor* infectious or contagious diseases." The public, in fact, are beginning to learn that very far from being the amiable fad at first supposed, "Christian Science" is a grave public danger.

Revival of the Dead.

READERS of the evening papers of the past few weeks must be aware that an American physician, Dr. Crile, of Cleveland, claims to have discovered a method by which the dead are restored to life. It will be remembered that, according to the lay papers, many animals which had been dead a considerable time were revived, and one boy, who came under Dr. Crile's care two hours *post mortem* was also restored. We confess to have been more than sceptical as to the existence of Dr. Crile or the genuineness of his remarkable results. However, on turning to the January number of the *Cleveland Medical Journal* we find that Dr. Crile at any rate is genuine, and that he makes at least some of the claims put forward on his behalf. He contributed to the above journal what is described as a "Preliminary Note on a Method of Resuscitation of Apparently Recently Dead Animals," and as its brevity is incomprehensible we take the

liberty of quoting it in full:—"By the combined use of intravenous infusions of adrenalin, artificial respiration and rhythmic pressure upon the thorax over the heart, animals dead as long as fifteen minutes were restored to life. Animals decapitated were made to live ten and a half hours." We eagerly await Dr. Crile's full report!

DR. D. J. CUNNINGHAM, of Dublin, has been appointed to the Chair of Anatomy at the University of Edinburgh, in succession to Sir William Turner.

SIR FREDERICK TREVES, Bart., F.R.C.S., has promised to open the new wing of the County Hospital, at Dorchester, his native town, on Monday next.

DR. GEORGE DICK, formerly of Birkenhead, has just been appointed Medical Officer of Health for the counties of Sutherland and Caithness, at a salary of £400 per annum, with an allowance of £100 to cover travelling expenses.

His Excellency the French Ambassador, supported by the Right Hon. the Lord Mayor of London and the Sheriffs, will preside at the 35th Anniversary Dinner in aid of the funds of the French Hospital and Dispensary at the Hotel Cecil on Saturday, April 25th.

Special Correspondence.

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

THE CHAIR OF ANATOMY IN EDINBURGH UNIVERSITY.—THE Curators of Patronage met on February 10th for the purpose of considering the vacancy in the Chair of Anatomy caused by Sir William Turner's appointment as Principal, and, having learned that Dr. Cunningham, of Dublin, was willing to accept appointment, unanimously decided that, in view of his pre-eminent qualifications, it was unnecessary to consider other applications, and that he should be invited to succeed Sir William Turner. The new professor, who is close upon fifty-three years of age, is a native of Crieff, and, like so many other distinguished Scotsmen, "a son of the manse." He was educated at Crieff Academy and graduated M.B., C.M. in 1874. Immediately thereafter he became a demonstrator of anatomy under Sir William Turner, and after holding that post for six years he was appointed, in March, 1882, Professor of Anatomy in the Royal College of Surgeons, Dublin, while in 1883 he obtained the office he has since held—Professor of Anatomy and Chirurgery in Trinity College, Dublin. Professor Cunningham, whose appointment to the chair in Edinburgh had been very generally anticipated, has made numerous contributions to scientific literature. He is acting editor of the *Journal of Anatomy and Physiology*, and his work on the topographical anatomy of the brain, on the lumbar curve in men and apes, on grantism, and on the brains of microcephalic idiots are well known to all, while his name is equally familiar to students as that of the author of "Dissector's Guide" and "Manual of Practical Anatomy." He has been an examiner in anatomy in several of the English Universities, as well as for admission to the services. He holds honorary degrees from Dublin, Oxford, Glasgow, and St. Andrews, and his position as an expert has been recognised by his appointment on several Royal and other Government Commissions, including that which inquired into the care of the sick and wounded during the South African War, and the War Office Committee on the physical standards required for candidates for commissions and recruits.

Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SEMI-TEETOTALISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a general practitioner who has for years past protested against the pernicious doctrine instilled into the infantile mind that alcohol in any shape or form as a dietary adjunct is a poison and injurious to health, may I be allowed to offer a remark or two, as the subject is referred to in your last issue.

To my mind it is almost impossible to conceive a more admirable and judicious compromise between the moderates and the extreme party than that suggested by the scheme in project, *viz.*, to limit the imbibition of stimulants to mealtime, a doctrine which, I venture to predict, would, if carried out in practice, not only tend to do away with what you suggest, *viz.*, the abominable practice of "nipping," which is nothing more nor less than chronic alcoholism, to a greater or less degree, but would, moreover, I think, secure almost the unanimous support of our profession.

As matters now stand it is useless to attempt to disguise the fact that only an infinitesimal proportion of medical men believe in total abstinence. And why? Because, I take it, the extreme party are unable to produce trustworthy facts to support their views, whereas the moderates have superabundant evidence in favour of their own.

The difficulty in handling this great question no doubt consists in approaching the extreme party with argument, as their prejudices are so intense that, like shying horses frightened at their own shadows, when we approach them they fly off at a tangent and alight for argument on lunatic asylums, prisons, workhouses, and insurance offices, as though these were indeed evidence of the value of total abstinence, whereas it is obvious to my mind that these cases only afford evidence of the reverse, *viz.*, of intemperance, and hence they throw dust in the eyes of the general public.

I maintain, therefore, that it is unworthy of medical men to propagate doctrines which are untenable, and, moreover, a reflection on their judicial capacity, and a source of undoubted danger to the public health.

I am, Sir, yours truly,

CLEMENT H. SERS.

Queen's Road, Peckham, S.E.,

February 13th, 1903.

OBJECTIONABLE ADVERTISEMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In discussing the subject of your leading article of to-day, it is necessary to free one's mind from cant, and to recognise that with few exceptions newspapers of every class are merely commercial speculations; the one paramount aim of their proprietors being the making of money. As in other trades although everyone may profess to pursue his aim by "legitimate means" alone, this term admits of very elastic interpretation in various minds. The income of all newspapers is mainly derived from advertisements. Every newspaper, even *The Times*, which beyond all others is well conducted in this respect, admits to its columns at least some advertisements which ought not to find a place in any respectable paper—advertisements which emanate from infamous knaves of various denominations besides medical quacks. No doubt the character of these advertisements is in some cases not recognised by the managers. On the other hand there exist papers whose columns are crowded with the advertisements of every class of impostor that lives by preying upon the credulous. Some journals, the chief ostensible aim of which is the exposure and denunciation of humbug, are filled with the announcements of financial sharks and medical quacks whose true character cannot be for a moment mistaken by the astute editors of these papers. The motto of the proprietors of

these journals—always to be distinguished from their servants, the editors—is no doubt *caveat emptor*; they pay an editor to preach high morality whilst themselves amassing wealth by such more than questionable devices. The papers most given to the indirect encouragement of fraudulent medical quackery are such as devote themselves editorially to the cults of anti-vivisection, and anti-vaccination, and are the organs generally of the large section of the public who hate science and are bitterly opposed to scientific progress. The proprietors of papers of this class probably consider it no more necessary they should agree with the opinions their editor expresses than the keeper of a sweet-stuff shop thinks himself bound to diet himself exclusively on the trash he purveys to the public. It is not the fault of the shop-keeper if a vast amount of harm is caused by abuse of the useful article he sells, and it is not the fault of the owner of a paper if the result of its preaching upon the minds of foolish readers is to drive them into the hands of the quacks who use its advertising columns to promulgate their lying statements. This is, after all, the broad effect of destroying the confidence of the simple public in medical science and in the medical profession, and it is this fact together with a picture of the misery which quackery inflicts upon suffering humanity which needs bringing home to the minds of newspaper proprietors, some of whom, at least, must have a conscience capable of being touched by such an exposure.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.

February 11th, 1903.

CHLOROFORM IN DENTAL OPERATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Dr. Kirkpatrick has placed the public not less than the profession under an obligation by his clear, complete and unanswerable statement of the case against chloroform as a dental anæsthetic, in the issue of the MEDICAL PRESS AND CIRCULAR of February 11th; and it is to be hoped his arguments will help to put a stop to the reckless use of an agent which, always involving risk to life, ought never to be employed for operations so trivial as those of dentistry. In spite of scientific theories and in spite of the reiterated opinion of so competent an investigator as Dr. Lawrie, namely, that chloroform may be made perfectly safe if a particular method of administration be carried out, the fact remains that a certain mortality attends the use of this anæsthetic, and deaths, moreover, occur, not only under the hands of careless or ignorant operators, but even occasionally under those of the most competent and careful of practitioners. The use of chloroform in dentistry, except in some very rare cases, would be forbidden if no other efficient substitute were to be had; but with nitrous oxide gas now available any excuse for substitution of the more deadly agent has been destroyed. The gas is not in itself a lethal agent; and the few fatal results recorded during its use have been due almost without exception to fortuitous circumstances rather than to the anæsthetic. Narcosis from the gas can be prolonged sufficiently in minor surgery associated with dental disease, as, for example, in tapping the antrum; and the fact that dental surgeons engaged constantly in performance of these operations virtually never employ another agent suffices to show that no other is really necessary. More than once in your columns I have expressed the opinion that to give chloroform for a simple dental operation with a fatal result deserves a verdict of manslaughter to be returned against the administrator; and I hold that the culpability is not much less even when the patient is recumbent and prepared as for a major operation instead of being seated in a chair in a position and under conditions inviting mishap. If after the repeated warnings which have been given practitioners can be found reckless enough to disregard them it is to be hoped a sharper lesson may be administered on occasion by

perhaps a medical coroner who happens to be properly acquainted with the facts of this question.

I am, Sir, yours truly,
HENRY SEWILL.

Cavendish Square, February 12th, 1903.

Death of a Lady House Surgeon.

THE death is announced of Miss Ellen Sharp, senior house surgeon at the Hull Victoria Hospital for Sick Children, consequent upon an attack of influenza. So sudden and unexpected was the death that an inquest was deemed necessary, when a verdict of death from natural causes was returned.

The Fleetwood Friendly Societies.

IT was announced last week that the place of the medical officers who have resigned their connection with these societies in consequence of the refusal of the latter to concede adequate terms had been filled by the appointment of a Manchester practitioner, but Dr. Homer, the gentleman in question, appears to have consented in ignorance of the actual situation, and it is to his credit that on becoming apprised thereof he at once withdrew. When it is remembered that the societies refuse to raise the medical contributions per head to four shillings per annum, a sum which certainly does not err on the side of extravagance, it is evident that justice is on the side of the doctors, and it is sincerely to be hoped that no "outsider" will intervene.

An Overdose of Morphine.

THE death of Dr. James Waters Harrison from an overdose of morphine is reported to have taken place on the 12th inst. ant. A note was found to the effect that he had taken an overdose of the drug.

Vital Statistics.

THE deaths registered last week in the eighty great towns of the United Kingdom corresponded to an annual rate of 18.3 per 1000 of their aggregate population. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—from all causes, 30.0 in Dublin, 25.0 in Glasgow, 25.0 in Belfast, 22.0 in Manchester, 22.3 in Bootle, 22.4 in Bury, 22.5 in Bradford, 23.0 in Newcastle-on-Tyne, 23.3 in Liverpool, 23.5 in Wigan, 24.2 in Preston, 24.8 in Tyne-mouth, and 31.3 in Hanley. From measles, 1.2 in Manchester and in Salford, 1.5 in Newport (Mon.), 2.2 in Merthyr Tydfil, and 3.4 in Wigan; from scarlet fever, 3.4 in Wigan; from diphtheria, 1.2 in Salford, 1.4 in Coventry, and 2.5 in Hanley; and from whooping-cough, 1.4 in Preston, 1.5 in Croydon and in Merthyr Tydfil, 1.6 in Hanley and in Stockport, 1.8 in Rotherham, 2.0 in Tynemouth, 2.4 in Grimsby, 2.9 in Tottenham, and 5.0 in Great Yarmouth. Seven deaths from small-pox were registered in Liverpool, and one each in Birmingham, Bootle, Bolton, Leeds, Sheffield, Rotherham, and Hull, but not one in any other of the large towns.

Medical Society in London.

THE anniversary dinner of this society is announced to take place at the Whitehall Rooms, Hotel Metropole, on Saturday, March 7th, at 7.30 p.m.

Trinity College, Dublin.

THE following passed the final examination in surgery at the Hilary Term, 1903:—Seaton S. Pringle, Thomas L. Sands, Demetrius Jacovides, Joseph Wallace James T. M'Entire, William Wiley, Thomas Ff. Manning, Edward V. Collen, John F. Nicholson. Section A.: James G. Wallace, John Cunningham, Arthur A. M'Neight, Keith R. C. Hallows, Wright Mitchell, John A. Sibthorpe, John H. Waterhouse, George B. M'Caul, Robert Magill, James H. Thompson, John Chambre, Charles E. Fawcett, William Hassard, Cecil A. Boyd, Francis S. Crean.

Conjoint Examinations in Ireland.

THE following candidates have passed the examination for the Diploma in Public Health:—Wm. H. Hornbrook, L.R.C.P. and S.Irel.; J. M. Keegan, M.A., M.B., B.Ch., R.U.I.; J. McLiesh, M.B., B.Ch., R.U.I.; J. B. Stephenson, M.D. Durh.

Notices to Correspondents, Short Letters, &c.

✍ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

OBJECTIONABLE ADVERTISEMENTS.

The Editor of "Womanhood" and "Baby" writes us, in reference to the remarks on this subject contained in our issue of the 11th, that there are cases of amenorrhoea, not due to pregnancy, in which the administration of "pennyroyal and steel" are of great service. He states, moreover, that he does not accept such advertisements until he has obtained the assurance of an analytical chemist that the medicines cannot procure abortion. The words "removing all anxiety," he assures us, were inserted without his knowledge or consent. We are pleased to receive this explanation, but may point out that it is not the probable effect of the nostrums to which we took exception, but the wording of the advertisements in such a way as to lead the reader to suppose that abortion might be induced, and we adhere to the view that these advertisements are, for the most part, specially designed to convey that impression. It is incumbent on editors to see that their journals are not made use of for any such disreputable purpose.

DR. C.—Delay in visiting a serious case renders the medical officer always open to censure. Such cases should not be allowed to escape the memory. Once the responsibility is accepted, neither insufficient pay nor overwork can be pleaded as an excuse. During a press of work the more serious cases should be first attended to. The facts tending to mitigate the apparent neglect in the first case should have been at once notified to the authorities, and not kept back until a complaint had been lodged.

DR. H.—You can hardly expect a consultant to refuse his services to a patient who applies to him for advice. Should it, however, come to his knowledge, in the course of his examination, that the patient is, or has recently been, under the care of a local practitioner, he would usually consider it expedient to communicate his views to the latter as well as to the patient.

COLONIAL M.D.—We do not think there is any way for you to obtain the right to practise medicine in France, except by going through the whole curriculum at one of the Faculties, and this would entail your passing a tolerably stiff preliminary examination.

STUDENT.—We are informed that a new edition of the work has just been published by Messrs. Baillière, Tindall & Cox.

DR. J. PRICE WILLIAMS (Manchester).—We have done as requested, but you omitted to enclose the model report as announced.

E. C. I.—We are unable to confirm your belief that preference will be given to London-trained nurses, but it is quite conceivable that the nature or extent of previous training and experience will be taken into consideration in the selection, and this is quite reasonable. The term "trained nurse" is very elastic, and comprises varying degrees of excellence.

CLIPPINGS FROM LAY EXCHANGES.

MISSIONARIES NEEDED IN NEWPORT.

Dr. —, of —, Ind., died at 12.05 a.m. last Sunday, May 11th, 1902, in Terre Haute, from effects of a surgical operation for fistula in ano. About nine-tenths of the surgical operations of the present day result in death.—Newport (Ind.) State.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 18TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Professor C. B. Ball: Adenoma and Adeno-Carcinoma of the Rectum. (Erasmus Wilson Lecture.)

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Dr. A. W. Rowe: Demonstration on the Photomicrography of Opaque Objects as applied to the Delineation of the Minute Structure of Chalk Fossils.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Mr. H. Marsh: Clinique. (Surgical.) 5.15 p.m. Dr. G. H. Savage: Development of Insanity.

THURSDAY, FEBRUARY 19TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Clinical Evening. Cases will be shown by Dr. E. Cautley, Mr. F. Jaffrey, and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Clinique. (Surgical.) 5.15 p.m. Mr. J. J. Clarke: Tuberculous Disease of the Spine.

FRIDAY, FEBRUARY 20TH.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos Street, Cavendish Square, W.).—5.30 p.m. Clinical Cases by Mr. H. J. Curtis, Dr. G. A. Sutherland, Dr. J. Taylor, Dr. A. Morison, and Dr. L. Guthrie. Paper:—Dr. G. Carpenter: On Cases of Uncomplicated Myocarditis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Mr. E. Clarke: Clinique. (Eye.) 5.15 p.m. Dr. H. L. Barnard: Acute Appendicitis.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover Square, W.).—Casual Communications will be given by Mr. C. Robbins and Mr. Golding Bird. Paper by Mr. J. B. Parfitt, on "A New Anatomical Articulator."

Vacancies.

Birmingham Corporation Waterworks, Elan Valley, Radnorshire.—Resident Medical Officer. Salary £200 per annum, with board, lodging, and drugs provided. Applications to Mr. B. R. Body, Hon. Sec., Elan Valley Sick Club, near Rhayader, Radnorshire.

Birmingham Corporation Waterworks, Elan Valley, Radnorshire.—Resident Surgeon. Salary £250 per annum, with board and lodging. Applications to Mr. E. Antony Lees, 44, Broad Street, Birmingham.

Stockport Infirmary.—House Surgeon. Salary £100 per annum, with board, washing, and residence. Applications to the Secretary.

Rotherham Hospital and Dispensary. Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing. Applications to E. S. Baylis, J.P., 19, Moorgate Street, Rotherham.

Kent County Asylum, Barming Heath, Maidstone.—Fourth Assistant Medical Officer. Salary £175 per annum, with furnished quarters, attendance, coal, gas, garden produce, milk, and washing. Applications to F. Pritchard Davies, M.D.

Newcastle-on-Tyne Dispensary.—Two Visiting Medical Assistants. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 41, Mosley Street, Newcastle-on-Tyne.

Borough of Torquay.—Medical Officer of Health. Salary £400 per annum. Applications to Fredk. S. Hex, Town Clerk, Town Hall, Torquay.

Royal Dental Hospital of London, and London School of Dental Surgery, Leicester Square, W.C.—Demonstrator. Salary £200 per annum. Applications to Morton Smale.

Royal Dental Hospital of London, and London School of Dental Surgery, Leicester Square, W.C.—Demonstrator. Salary £100 per annum. Applications to Morton Smale, Dean.

Royal Dental Hospital of London.—Curator to the Pupils' Mechanical Teaching Department. Salary £200 per annum. Applications to Morton Smale, Dean, 32, Leicester Square.

Lanark District Asylum, Hartwood.—Third Assistant Medical Officer and Pathologist. Salary £120 per annum, with fees, board, washing, and residence. For full particulars apply to the Medical Superintendent (see advt.).

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer. Salary £100 per annum. Applications to Thomas Hayes, Secretary.

Owens College, Manchester.—Junior Demonstrator in Physiology. Salary £100 per annum. Applications to Sydney Chaffers, Registrar.

Dorset County Hospital, Dorchester.—House Surgeon to reside and board in the Hospital. Salary £100. Applications to the Chairman of the Committee.

St. Vincent's Hospital, Dublin.—Specialist for Diseases of the Throat and Nose. Applications to the Secretary before March 1st (see advt.).

Appointments.

BATES, RAYNER WINTERBOTHAM, M.D., F.R.C.P. Lond., M.R.C.S., J.P. Consulting Physician to the Berkeley (Glos.) Hospital.

BERKELEY, AUGUSTUS FREDERICK MILLARD, L.R.C.P. & S. Edin., L.F.P.S. Glas., Medical Officer for the Sixth District and Public Vaccinator for the Third Rural District, by the Bath Board of Guardians.

BONAR, THOMAS MITCHELL, M.B., C.M. Glasg., Medical Officer for the Tregony and Probos Districts by the Truro Board of Guardians.

BRYAN, FRANK, B.C. Cantab., House Physician to the Derbyshire Royal Infirmary.

CAMPBELL, COLIN A., M.D. Toronto, Third House Surgeon to the Royal London Ophthalmic Hospital.

Dow, W. B., M.D. St. And., F.R.C.S. Edin., Medical Referee under the Workmen's Compensation Act, 1897, for the Sheriffdom of Fife and Kinross.

FRASER, C. L., F.R.C.P., F.R.C.S. Edin., Certifying Surgeon under the Factory Act for the Berwick-on-Tweed District.

HOPK, C. M., M.B., Ch.B. Glas., House Surgeon to the Derbyshire Royal Infirmary.

TARGETT, J. H., M.S. Lond., F.R.C.S. Eng., Obstetric Surgeon to Guy's Hospital.

Births.

HULKE.—On February 12th, at Ivy House, Walmer, the wife of Sydney Backhouse Hulke, F.R.C.S., of a daughter.

JENNINGS.—On February 11th, at Old Brompton, Chatham, the wife of Lieut. Colonel Jennings, R.A.M.C., of a son.

WATSON.—On February 11th, at 130, Queen's Road, Finsbury Park, N., the wife of George de B. Watson, M.B., C.M., of a daughter.

Marriages.

HILLEARY—FARIE.—On February 11th, at St. Peter's, Cranley Gardens, George Edward, third son of Fred. E. Hilleary, L.L.D., Bleak House, Stratford, Essex, to Amy Katherine Wellesley, eldest daughter of the late Robert Farie, M.D., and of Mrs. Farie, of Ruthven, 29, The Boltons, S.W.

RICHARDSON—MCLEAN.—On February 11th, at St. Paul's Church, Clifton, Bristol, Hugh Richardson, M.B., C.M. (late R.A.M.C.), St. Andrew's, son of the late Henry Cockburn Richardson, I.C.S., to Elizabeth, daughter of the late Patrick McLean, Esq.

Deaths.

BLACKETT.—On February 12th, at Shaftesbury Lodge, Beccles, Harry Elton, youngest son of the late Edward Ralph Blackett, M.D., of Wangford Suffolk, in his 21st year.

BRAKE.—On February 8th, at San Remo, Craneswater Park, Southsea, Surgeon-General Brake, late I.M.S., aged 75 years.

DIXEY.—On February 13th, at his residence, Moss Hall Villa, North Finchley, Augustus Edward Dixey, M.D.

SHARP.—On February 9th, at the Royal Victoria Hospital, Hull, Ellen Mary Sharp, M.B. Lond., House Surgeon to the Hospital, aged 28 years.

WIGAN.—On February 15th, at his residence, Clarence House, Portishead, Somerset, George Wigan, M.D.

Lunacy and Law.

THE CARE AND TREATMENT OF PERSONS OF UNSOUND MIND IN PRIVATE HOUSES AND NURS- ING HOMES. (a)

By ERNEST W. WHITE, M.B.Lond., M.R.C.P. Lond.,
President Elect of the Medico-Psychological Association of Great
Britain and Ireland; Professor of Psychological Medicine,
King's College, London; Resident Physician and
Superintendent, City of London Asylum.

(Concluded from page 162.)

NEXT let us consider a case where a young lady, suffering from incipient insanity, was in a nursing home, uncertified, under the charge of a mental nurse for two months, at the end of which time she had to be certified, and sent to a public asylum receiving paying patients. The lady was admitted into the City of London Asylum in July last, suffering from melancholia. She was on admission agitated and emotional, heard voices which told her of unfortunate occurrences to her friends, thought she had been very wicked, was troublesome with her food, etc. After moral and medicinal treatment she steadily improved, and was recommended for discharge as recovered in December last, then having been convalescent a month. She weighed on admission in July 7 st. 11 lbs., and on discharge 9 st. 11 lbs. She told me that in the nursing home nothing was done for her, and the life was painfully dull and monotonous; the nurse sat near her all day doing her needlework, and seldom spoke, but watched her carefully. There were three other ladies in the house, of whom she saw but little; she thought they were mental cases.

The advantages of uncertified single care ?

1. Avoidance of the so-called "stigma of insanity."
2. Secrecy.
3. The so-called continuity of medical treatment (doubtful if unskilled).
4. Freedom from contact with other persons of unsound mind.
5. Domesticity.

The disadvantages of uncertified single care ?

1. Insufficient general and moral control of the patient. (There is no legal power of detention, for the patient is in full possession of civil rights.)
2. The patient's property is not safeguarded from unworthy relatives, solicitors, medical men, caretakers and nurses.
3. Frequently there is unskilled medical treatment, or none at all.
4. Unskilled nursing as a rule.
5. Monotony in some out-of-the-world place.

(a) Read at the General Meeting of the Medico-Psychological Association held at the County Asylum, Micklever, near Derby, February 12th, 1903.

6. Interference of friends.
7. Want of official supervision.
8. Incapacity of caretaker.

The want of official supervision is, perhaps, the most serious of these disadvantages, for I have heard of inhumane and cruel forms of personal restraint which have been used upon these unfortunate patients even since the passing of the Lunacy Acts, 1890-91, and is not this what we should expect with no official supervision? In 1893 we sent two nurses to a well-known southern seaside resort for a private patient, who had been acutely insane, but uncertified for seven weeks. The nurses found the patient roped by the wrists and ankles to the four corners of the bed. She was in a filthy state, as she had been tied down for days. Men had been called in to assist in the roping process. The patient's wrists and ankles were much marked, bruised and abraded. The hospital nurses in charge of the case were afraid for their lives, but upon our nurses clearing the room and removing the ropes, the patient accompanied them without a murmur, and gave no trouble on the journey.

I have heard of another lady being roped to a bedstead like a monkey to a pole, with just sufficient rope to allow her to attend to the calls of nature.

We admitted, not long ago, a lady who for months had been at a seaside resort with a caretaker in whose house a room had been fitted up as a strong room, with iron bars in place of the lower panels of the door. An occasional peep at the patient was taken through the "grille." This, I presume, was supposed to be curative treatment under single care. The physician, who was an eyewitness in the last two cases, is present to-day, and will verify my statements with fuller details.

Let there be no disguising the fact, mechanical restraint of an advanced type is often resorted to with uncertified patients in single care by unskilled nurses and heartless caretakers. We who know how the excited patient frets and struggles even to exhaustion under mechanical restraint, and how fearfully it reduces the prospect of recovery, must raise our voices in no uncertain strain, in the interests of suffering humanity, against any relaxation of the law which will open the gates any wider to such barbarisms.

What is the suggested notification of mental cases ?
It is that in all cases of mental unsoundness in which certification and compulsory detention seem needless, and in borderland cases, there shall be a system of notification to the Commissioners in Lunacy by any one receiving payment, to the effect that "A. B. is a person of unsound mind, and is not a proper person to be detained." It has been also suggested that this notification shall be to the local authority. It is presumed in the first instance it will be followed by the visit of a Commissioner in Lunacy, or some one deputed by the Commissioners, and in the second by a medical officer appointed by the local authority.

What would be the advantages of such notification?
They would be the same as those given under the heading uncertified single care (*vide supra*).

What would be the disadvantages ? These again would be identical with those given under uncer-

tified single care (*vide antea*) with, in addition, increased official expenditure from the necessary appointment of deputy or district Commissioners to inquire into the numerous class of cases which would rapidly crop up. In an article on Lunacy Law Reform in the *Lancet* of December 27th, 1884, I suggested the appointment of deputy Commissioners in the following terms:—"District experts as medical officers of insanity, occupying analogous posts with those of coroner and medical officer of health, with fixed salaries, these officers to be elected from their experience in the specialty, and to be allowed to practice as pure physicians. Their duties would be to examine all supposed lunatics in consultation with the medical man in attendance, to sign all necessary certificates, to visit all single patients, and patients in private asylums in their districts, to report thereon from time to time to the Commissioners in Lunacy, and so act as district agents for the Commission or deputy Commissioners. They would have power to order the discharge of any single patient, or any patient from any private asylum in the district, should such a course be desirable on account of recovery or otherwise. They would also have authority to prevent the removal of any patient by his or her friends, when such removal was calculated to be fraught with danger to the patient or others." Many of the suggested reforms in that article were adopted in the Lunacy Acts, 1890-91. This was not, for the obvious reason, expense.

I am afraid notification, unless under the most efficient official supervision, would encourage a continuance of the evasion of the law, or at least would delay proper remedial treatment in consequence of the patient not being under proper moral control.

What cases are suitable for care and treatment as certified single patients?

1. Quiet and harmless tractable imbeciles.
2. Quiet and harmless chronic demented.
3. Certain general paralytics in the last stage.
4. Hyper-sensitive patients convalescing from melancholia.

What cases are unsuitable? All others.

What cases are suitable for care and treatment uncertified?

1. Transient cases of mania and melancholia dependent upon drink.
2. Certain borderline cases where the symptoms are undeveloped.
3. Other cases in which the symptoms are not severe, and which have a definite exciting cause not likely to be long operative.

How should they be protected against abuses? By proper and complete official supervision. I have been for years past, and am still, in favour of the appointment of deputy Commissioners for districts as defined above, such appointments to be made from those skilled in the treatment of mental diseases.

What is the suggested temporary care and treatment of the incipient insane? In 1899 the Joint Committee of the British Medical and Medico-Psychological Associations, of which I have been a member by your courtesy since its formation, waited upon the Lord Chancellor at the House of Lords. It urged the necessity of early legislation for the incipient insane. It told him how numberless borderline cases were smuggled away in the country, the Channel Isles, and on the Continent, to avoid legal certification, how their chances of recovery were imperilled thereby, and how the possibilities of inhumane care existed. As a consequence, he introduced into the Lunacy Bill of 1900 the following clause, adapted from the existing clause in Scottish Lunacy Law:—

1. "If a medical practitioner certifies that a person is suffering from mental disease but that the disease is not confirmed, and that it is expedient with a view to his recovery, that he be placed under the care of a person whose name and address are stated in the certificate, for a period therein stated, not exceeding six months, then during that period, the provisions of Section 315 of the principal Act shall not apply.

2. "The certificate must not be signed by the person under whose care the patient is placed.

3. "Where a medical practitioner signs any such certificate he shall within one clear day after signing it, send a copy of it to the Commissioners, and the Commissioners may visit the patient to whom the certificate refers."

I believe this clause, with its three sections, will meet all the requirements of the case for the insane of the upper and upper-middle classes provided the deputy Commissioners before named be appointed.

As several of the county and borough asylums are at the present time admitting private patients in large numbers, would it not be well that the voluntary boarder system appertaining to the registered hospital and private asylums should be extended to public asylums? There are many patients, incipient and borderline melancholic cases, who lack self-confidence, and who, if they can place themselves under the sheltering wing of an institution giving them medical and general supervision, will rapidly regain their mental balance and thus escape certification. Those who have had ample experience of the voluntary boarder consider that the legislation regarding him has been productive of much benefit.

Having surveyed the subject in detail we must now consider the various points, not already discussed, to which allusion was made by Sir William Gowers.

The contemplation from the train of the wall of Hanwell Asylum, we are told, prompted him to lead a crusade against the existing lunacy laws. He thought of those the wall excluded, and those it included. Now the wall of Hanwell (the oldest of our London County Asylums) is an anachronism! The asylums of to-day have no walls! and while the buildings include those committed to the humane and skilled care of the medical officers for treatment, they do not exclude those who desire to gain knowledge regarding mental diseases. The lovelorn Kentish cavalier, when he wrote in his prison in Westminster the lines the first of which Sir William quotes, little thought they would be applied to an asylum for the insane some two hundred and fifty years later. Let us contemplate these lines:—

"Stone walls do not a prison make,
Nor iron bars a cage,
Minds innocent and quiet take
That for an hermitage;
If I have freedom in my love,
And in my soul am free,
Angels alone that soar above
Enjoy such liberty."

We do not acknowledge the walls as part of our treatment to-day. Nor are iron bars necessary in institutions for the insane. They appear (as we have seen to be only required for uncertified patients in single care. Our cavalier, although imprisoned, was happy withal in the freedom of his thoughts.

Sir William Gowers tells us that in many cases certification is harmful and unnecessary. Many of us differ from him upon this point. We recognise in certification the means of placing the patient under proper control for treatment, and we are satisfied that the chances of recovery are in many instances greatly increased thereby. The cases quoted by him as suitable for treatment without being duly certified were peculiarly unfortunate. They all had delusions of persecution, and these patients, as we alienists know, may at any time become actively homicidal or suicidal by impulse. They should certainly all have been under certificate, both in the interest of the public and of themselves. Sir William Gowers states that every patient received for payment and uncertified is a free agent, can leave or be removed at any time. Such is not my experience with uncertified insane patients in private houses and nursing homes. Furthermore, I do not admit that certification is in any way disastrous to the patient, or the painful distress to the friends it is stated to be. Sir William Gowers speaks of the "divorce of psychological medicine from general medicine." There is no divorce. They have always been separate and distinct, and must remain so from the very nature of mental disease, and the treatment demanded. The moral side of this treatment is all important, the medicinal only accessory.

and that in quite a minor degree. The days of mechanical restraint and of the exhibition of medicinal nostrums for insanity are past and gone. We have too many proofs of the value of our more enlightened system to wish to revert to them. Let the general body of our profession make themselves thoroughly acquainted with this system; they will then recognise the vital importance of the daily contact of the mental physician with his patient, to control the management and moral treatment of the case, the necessities of which are ever varying.

We are told that the "master of method" is necessary for the full and proper development of the normal mind of youth, that a scholar who has not had training as a schoolmaster is unequal to perfecting a student's education in classics, mathematics or the higher sciences. How much more, then, must the "physician of method," trained by long experience and daily contact with the insane, be essential for the re-education of the abnormal mind, for the replacing of the unhinged mind upon its hinges, for the dispelling of the hypochondriacal delusions of the melancholiac, and for the calling back to mental life again of the quasi-demented patient living in mental stupor?

Speaking after thirty years' experience as a public asylum physician, and thirteen as a lecturer on mental diseases, I would state unhesitatingly that to comprehend the vagaries of the mind diseased, to lead that errant mind back to health, and to recognise the means by which this end can be effected are problems only to be solved by those who have made the insane their intimate and life-long study.

Note appended, February 7th.

Sir William Gowers has just published in pamphlet form his address of November 20th, 1902, with a note. I observe the title is altered. It now reads "An Address on the Prevention of Insanity." Would not "on the Evasion of Insanity" be more appropriate? In the note he draws attention approvingly to Sir William Church's suggestion that notification should be to the local authority, the facts of each case to be subsequently investigated by the medical officer of health or some other official appointed by the local authority. What does the medical officer of health know of mental diseases? Is he qualified to decide such a case? and who is the other official suggested? Who but one skilled in the treatment of insanity is qualified to decide whether the conditions under which the patient is placed are such as are likely to promote recovery, or whether certification is necessary in his or her interest? Sir William Gowers is in error when he states that provision is already made for the reception of borderline patients as voluntary inmates of public asylums. At present voluntary boarders cannot be taken in county or borough asylums, but only in registered hospitals and private asylums. He tells us, moreover, that it is a sarcasm to suggest that patients on the verge of mental derangement would place themselves in lunatic asylums. Is he not conversant with that large class of cases of incipient melancholia in which the patient lacks self-confidence and self-reliance, is imbued with a sense of impending trouble, and consequently eagerly seeks admission within the walls of a private asylum as a voluntary boarder, and expresses a feeling of relief when under the sheltering wing of the institution? The limitation Sir William Gowers takes objection to in connection with the clause for the treatment of incipient insanity—"that no person under this section shall receive more than one patient at the same time"—is in accordance with the principle of the Lunacy Acts, 1890-91, that private asylums are to die out by gradual extinction, for no new licence can be granted. To receive more than one patient would constitute a private asylum. Sir William Gowers objects, also, to the sanction of the Justices of the Peace being necessary, and adds that "such a sanction could only be a useless formality." He forgets that it is right that the liberty of the subject should be taken only by some mode of judicial procedure.

THE RELATION OF ANÆSTHETICS TO SHOCK. (a)

By J. BLUMFELD, M.D. Camb.

Senior Anæsthetist to St. George's Hospital, &c.

His object, he observed, was to raise a discussion upon the question of the part which anæsthetics play in the prevention of shock; he was aware that exactly opposite opinions were held on this point, some observers believing that the shock present after certain operations is entirely due to the anæsthetic, and others that it is due entirely to the operative procedures, and would be much worse without the anæsthetic. Dr. Blumfeld also referred to the difference of opinion with regard to shock and the depth of anæsthesia, some anæsthetists holding that shock is more commonly met with in light than in deep anæsthesia, and others exactly contrary views. To avoid confusion, Dr. Blumfeld stated that in speaking of shock he also included collapse, for both were conditions of prostration in which failure of the circulation played a prominent part. The speaker reminded the meeting that death from the shock of operation was much less frequent now than it was in the old days, partly because anæsthetics have abolished pain, which was an important factor in the causation of shock, and partly by protecting the central nervous system from receiving impressions of the serious damage being done to the tissues by the operation. Beside the well-known "bleeding," so to speak, of the patient into his splanchnic area during shock, there was also the general reflex paralysis affecting, besides all the other functions of the body, especially the normal interchange between the blood and tissues, which is characterised occasionally by patients suffering from shock not corresponding to such stimuli as strychnine and alcohol at the time of exhibition of these remedies, but subsequently manifesting symptoms of overdose. It is because shock is a reflex affair that anæsthetics can be looked to with confidence to influence it, since they have such a powerful influence on all the other reflexes; but their relation to shock differs from their relation to the other reflexes, in that whereas they can only abolish the latter, they can both abolish and also produce shock, or a condition exactly resembling it. Dr. Blumfeld was strongly of opinion that since both shock and deep chloroformisation are characterised by a marked fall in blood-pressure, a deep degree of anæsthesia should, as far as possible, be avoided in operations upon patients already suffering from shock or likely to suffer from it as a result of the operation. He did not wish to be understood as including ether in these remarks, since there was no evidence to show that ether produced shock in the same way as chloroform, although it often gave rise to a collapse after a prolonged administration of large doses in the kind of case referred to. The difficulty in assigning its proper place to the producer of collapse, to the operation on the one hand, and to the anæsthetic on the other, was great, and is usually not duly appreciated by the surgeon, who is apt to forget the immense importance of economising the time during which parts of the body, such as the bowels, for instance, are being subjected to manipulation. The longer such pro-

a) Abstract of Paper read before the Society of Anæsthetists February 6th, 1903.

cedures last the more easily is shock induced. The purely nervous element has also to be taken into consideration, and adds greatly to the difficulty of determining the cause of shock. Dr. Blumfeld here quoted undoubted cases of shock from nervous influences.

Because anæsthetics had the power of producing shock, Dr. Blumfeld did not think it right to assume that in cases already suffering from shock general anæsthetics were to be avoided, but that there should be a proper appreciation of the difference between light and deep anæsthesia, and that a general anæsthetic should always be given, but only to a light degree, and that any attempt to keep such cases deeply under chloroform is highly dangerous. In a recent letter to the *Lancet* of January 17th, page 199, on the surgical treatment of perforated typhoid ulcer, Mr. H. J. Curtiss had raised the question of anæsthetics, and had advocated the use of local anæsthesia, assuming an extra danger from general anæsthesia in these cases. Dr. Blumfeld believed the Society were not prepared to admit this assumption, but that they were in a position to say with regard to such cases that if an operation must be performed there was less danger in performing it if a general anæsthetic were properly given than there was in performing it without one.

NOTE ON CYSTS OF THE ROUND LIGAMENT. (a)

By H. MACNAUGHTON-JONES, M.D., M.A.O.,
F.R.C.S.I. & E.

MANY years since I had an experience in a case of rupture of the bowel which I think was unique. I quote it now from memory, for I have, unfortunately, lost the notes.

A young married woman was sent to me by her medical adviser, who wished me to give an opinion as to the nature of an inguino-labial swelling, as he was doubtful as to its being a hernia of the bowel. I found it partly reducible and answering to all the tests of hernia. I came to the conclusion that it was a hernia, and advised an operation for its radical cure. The friends did not like the thought of this, so a few days after I saw her she was taken to the late Sir Spencer Wells, who expressed the opinion that it was a hydrocele of the round ligament, and that it was not necessary to interfere. I heard no more of the patient until some twelve months subsequently, when I was sent for hurriedly late in the evening. She lived at Wandsworth. When I arrived I had the following history from the same medical man.

She had gone on without any trouble until a few days before I saw her, when the swelling suddenly increased in size, became painful and more tense. Efforts to move the bowel had failed, and the reason for my summons was that there had been sudden collapse with cessation of the pain, and all the symptoms of a ruptured bowel. Of the occurrence of this I had no doubt when I saw her. There were no facilities for operating on the spot, so within a few hours she was safely in a Home, and I made an artificial anus in the right inguinal region. I must here mention that within a recent period a swelling, less in degree but of the same nature, had appeared at the left

side. The patient did well, and the artificial opening had closed perfectly, when quite suddenly the area over the swelling at the left side became red and painful. After some palliative efforts to restrain the inflammation I decided to open what I believed to be another bowel abscess, and found when I did so much the same state of things as had existed on the right side—an opening in the bowel and fæcal matter in the abscess. I again made an artificial anus, and in due time was pleased to find the bowel acting. Its movements were natural and healthy. I had no doubt of the patient's recovery, and looked on her as convalescent. Unfortunately, the strict rules of diet I had laid down were now disregarded in the Home, and without my knowledge she was given some steak with capers, of which she ate plentifully. She was seized with sickness, vomiting and pain. General peritonitis rapidly set in, and she died some thirty-six hours from the onset of the symptoms. I was naturally anxious to have an autopsy, but the friends would not consent, and it was with difficulty I succeeded in obtaining permission to investigate the state of the parts at either side where I had operated. At the right side I found the lumen of the bowel quite restored. At the left, in the neighbourhood of the recent rupture, there was an opening, an escape of fæcal matter, and a large quantity of undigested capers. This, I believe, was the cause of death—obstruction and peritonitis set up by these latter.

I have never since seen a hernia in a woman for which I have not advised the radical operation. I go so far as to say that no woman who can be operated upon should be the possessor of a truss. From the time of the occurrence of this case until quite recently I have had no difficulty in the diagnosis of any swelling in the inguino-labial region.

The anatomical points of gynecological interest in connection with the round ligaments are as follows:—The permanency of the plica gubernatrix from the Wolffian body (the analogue of the gubernaculum in the male) constituting the round ligament of the ovary in the female, the attachment of which to the uterus arrests descent of the ovary except in rare cases, when, passing by the canal of Nuck, the ovary may reach the labium; the peritoneal accompaniment of the round ligament which corresponds to the processus vaginalis in the male, and which, when not obstructed, forms in its prolongation the patent canal of Nuck; thirdly, the presence of areolar tissue and vessels in and around the round ligament, and the prolongation of the transversalis fascia from the internal abdominal ring. Now, by these anatomical and histological data we can explain the presence of intestinal hernia, epiplocele, hydrocele, incarcerated ovary and a cyst or fibroma in the canal and labium. The diagnosis is not, as in the cases I now record, always easy. Pozzi, in speaking of encysted fluid of cysts in the canal, says that the persistence of the canal of Nuck is looked upon by most authorities as explaining their presence, though this is denied by Duplay, and Schroeder has reported a case in which he was able to return the fluid into the abdomen. This demonstrated a communication of the cyst with the peritoneal cavity, thus establishing a resemblance to congenital hernia in the male. As will be seen, this is exactly what occurred in one of my own cases. Sometimes the cyst may

(a) Read before the British Gynecological Society, February 12th, 1903.

be seated in the *interior* of the round ligament. This may be due (Weber) to a persistence of the female gubernaculum in its foetal form.

A woman, *æt.* 26, unmarried, consulted me early in 1902 for a swelling in the right groin. This she first noticed at the end of 1901. There was but little pain, but it varied in size, and told against her in her work. On examination I found a swelling in the right inguinal region, extending almost into the labium. There was an impulse on coughing, and by steady pressure in the horizontal position the swelling was reduced and practically disappeared. This collapse of the tumour puzzled me, as I had rather inclined to the view that I was dealing with a hydrocele of the round ligament. It was not possible for her to undergo an operation at the time, so I devised a special horseshoe air-pad truss to wear over the abdominal ring. This she wore for several months, when I again saw her, and then I found that the swelling had practically disappeared. I advised that she should still wear the truss. Shortly after this she had serious domestic trouble, and became very thin. The truss slipped up from the position I had intended it to be worn in, and the swelling reappeared again, and now gradually increased to the size of a large pigeon's egg. When I next saw her I found this swelling was tense, and not now influenced by pressure. I advised operation. I was not confident of my diagnosis, and though I now leaned to hernia, I had a doubt as to the cystic nature of the tumour. On dissecting down to the surface of the sac this was seen to be of a deep blue colour. The wall consisted of a thin membrane, and was covered with vessels. It had much the appearance of the wall of a hernial sac. On opening it, fluid blood escaped. The sac was attached to the round ligament, and had formed adhesions in the canal up to the internal abdominal ring. I dissected out the sac and explored the internal ring, which I found empty. It was clear that the canal of Nuck was patent, and that the cyst was a hydrocele, into which blood had escaped. The round ligament was drawn forwards and fixed at the internal ring, which was then closed, and the canal itself was obliterated by a series of cross sutures which included the round ligament. The wound healed aseptically.

For the second case I am indebted to Dr. Rœ Carter. A lady suffered from disease of the adnexa and incontinence of urine due to exaggerated ante flexion of a hypertrophic uterus; there was also what we believed to be an irreducible hernia, though with the experience of the last case before me a qualified diagnosis was given. Here also the tumour varied considerably in size. After the operations of salpingo-oophorectomy and fixation of the uterus were completed and the abdominal wound was closed, I opened the inguinal canal and found an isolated cyst about the size of a small walnut on which the round ligament was spread, and to which it was attached. There was no funicular process of peritoneum as in the last case; the internal ring and parts above the cyst being normal in their appearance and relations. The cyst was dissected out and the canal closed, as in the last case. Recovery has been perfect. In these two cases we have examples of two distinct types of round ligament cysts; the one obviously the consequence of a permanent canal of Nuck and connected with the persistent peritoneal

process. When I first saw the patient the fluid was evidently returnable into the peritoneal cavity. The other was a cyst, most probably arising in the areolar tissue in the round ligament, or possibly from a persistent embryonic gubernaculum. Both are liable to be mistaken for hernia, the latter possibly for an incarcerated ovary, or what is a more serious error, as in the first case I related, a hernia may be mistaken for a cyst or a hydrocele. Under any circumstances the safe rule, for every dubious swelling in the inguino-labial region in a woman, is to operate.

The Nettlesonian Lectures

ON THE

CONDITIONS WHICH MODIFY THE CHARACTERS OF INFLAMMATIONS OF THE SKIN AND THEIR INFLUENCE ON TREATMENT.

DELIVERED BEFORE THE MEDICAL SOCIETY OF LONDON
By H. RADCLIFFE CROCKER, M.D., F.R.C.P.,

Physician to the Skin Department, University College Hospital.

ABSTRACT OF LECTURE I.

INFLAMMATION OF THE SKIN.—It is about a century ago that Dr. Robert Willan published his treatise on inflammations of the skin, founding his classification of them on their most prominent clinical feature, dividing them into papular, scaly, vesicular, bullous and pustular forms.

Inflammations of the skin comprise more than half of all skin cases, six out of every ten patients having some form of dermatitis, and of these five-sixths come under eczema, psoriasis, impetigo contagiosa, lichen planus, erythema, and urticaria in hospital practice, but in private practice there are a very few impetigo contagiosa, and twice as many of lichen planus.

The inflammations set up by irritants differ according to the strength of the irritant. A strong irritant will set up a dermatitis in anyone exposed to it, and its character is usually recognisable, and perhaps even the kind of irritant which was the cause of it, as, for instance, crowded vesicular eruption on the palms from the dye called "aurantia"; an irregular bullous eruption from the application of a caustic liquid; Röntgen ray burns, the latter being characterised by the obstinately unhealing character of the ulceration produced, and by the close network of dilated vessels over the whole injured area.

The mild irritants usually require a special vulnerability on the part of the patient, and the eruption produced often resembles an ordinary inflammation of the skin such as an erythema or an eczema, and the cause is often not ascertained unless it is several times repeated, and always commences in an exposed part. Occupation eczemas, such as those of bakers, barmaids, French polishers, &c., are the type of this kind of dermatitis and frequently inflammation, starting at the irritated part, develops on distant parts, often symmetrically. Vulnerability to certain irritants once acquired often increases till the very slightest exposure is sufficient to bring on an attack. Iodoform dermatitis is an example, and it may be pointed out that handling the gauze is alone enough to start it in the predisposed.

ECZEMA.—In discussing the pathology of eczema we may take the papulo-vesicular type, the pathology whereof is still a matter of dispute. Probably the safest line is to not to ask, Is eczema parasitic? is it a blood dyscrasia? is it a neurosis? but to acknowledge that all these are factors, and to endeavour to estimate in what proportion each plays its part in any particular case. Once the inflammatory process is started, pus cocci, either the *Staphylococcus aureus* or the *Streptococcus pyogenes*, may, and often do, modify considerably the character of the inflammation, in some cases by the cultivation into virulence of a previously harmless organism, in others by the secondary invasion of one or other of these pus cocci.

Bockhardt's impetigo is a frequent precursor and concomitant of boils, and it should be promptly treated as a prophylactic measure against them. An untreated streptococcus impetigo may lead to a rapidly spreading erysipelas in an infant, and endanger the child's life. In the treatment of boils and carbuncles the aim should be the local destruction of the pus cocci as early as possible, and therefore early incision and disinfecting the cavity with carbolic acid solution before the pus cocci can travel along the lymphatics and set up a fresh boil some distance off.

In *pemphigus neonatorum* the bullæ have perfectly clear contents, and both the staphylococcus and the streptococcus have been found by different observers, the staphylococcus being the most frequent. It is generally a sign of unhygienic surroundings, but unless neglected, or derived from puerperal fever in the mother, it is readily amenable to treatment; under modern asepticism it is now never seen in lying-in institutions where formerly it was endemic.

Fungating papillary growths are apt to form on all chronic suppurating surfaces, and after some acute suppurations less generally recognised conditions dependent on pus organisms occurred. They are all pyogenic granulomas with different names according to the underlying diseases on which they develop: they may be tuberculous, syphilitic, and in the axillæ and groins form part of the symptomatology of pemphigus vegetans. The so-called botryomycosis hominis is an example of a fungating granuloma after acute suppuration. Hypertrophic scars also are probably avoidable by excluding pus organisms during the healing process of an open wound.

This diversity of lesion from the same organisms is largely due to the mode and depth of implantation in the skin of the pus cocci, and shows how far we have advanced on Willan's classification according to the primary lesion.

DERMATITIS AND SEBORRHOEA.—With regard to the modifications of dermatitis produced on a seborrhœic basis or the seborrhœides, it must be pointed out that seborrhœa oleosa is once again regarded as excess of secretion from the sebaceous glands, and not from the sweat glands as Unna advocated, and that Sabouraud ascribed it to a special micro-bacillus, the comedo also being due to the same bacillus. While the former fatty incrustation so common on the scalp is no longer regarded as a true seborrhœa, but a cell proliferation, chiefly of the horny layer, due, it is said, to the bottle bacillus and the seborrhœic micro-bacillus in combination, the secondary invasion of the *Staphylococcus aureus* and a grey coccus produce, if Sabouraud was correct, the various

seborrhœides, that is to say, the apparently trivial seborrhœa affords a favourable breeding ground for other more actively mischievous organisms.

The seborrhœides may be described as imitators of different forms of eczema, lichen, and psoriasis, and other inflammations, and Sabouraud ascribed to mixed infections of the pus and seborrhœic organisms the production of the pustular eruptions—acne varioliformis, acne furunculosis, chronic furunculosis of the neck, sycosis, acne keloid, and dermatitis papillaris capillitii. If these views of mixed infection are confirmed, and they are highly probable, it is an important generalisation which ought to lead to improved conceptions both of the pathology and treatment of many forms of dermatitis.

LOCAL ORIGIN OF GENERAL ERUPTIONS.—The lecturer then passed on to the consideration of the local origin of many general and symmetrical eruptions, and showed that while it was first pointed out by Brocq in relation to the somewhat acute disease called pityriasis rosea, it was capable of extension to other diseases, such as psoriasis and lichen planus, in their primary attacks. In pityriasis rosea there first appeared a single patch, generally in some part of the trunk, which slowly enlarged peripherally for eight or ten days, and then a widespread symmetrical outbreak occurred which might in a few days cover the whole body and upper segments of the limbs, the lower segments seldom being much involved, and after lasting three or four weeks the eruption gradually disappeared. In less typical cases the development might be slower, might stop more or less short of generalisation, and the tendency to spontaneous involution be much less, so that sometimes cases lasted for several months.

In first cases of psoriasis, the lecturer had frequently been able to trace the same mode of development, though, owing to the slower course of the disease, it was less obvious than in pityriasis rosea. For weeks, months, and occasionally even years, there might be only one or two patches, then they began to multiply; if slowly perhaps on the same limb only, and not very far from the original patch or patches, but either with or without the local extension; generalisation eventually took place, and in recurrences this sequela of events could no longer be traced. In lichen planus development from a single focus could not often be proved, but it was common for a few foci of the chronic form of the disease to be present for months or even years, and then suddenly for a generalisation of the more acute miliary form to occur, sometimes from a traceable, and sometimes without a traceable, exciting cause.

The most feasible explanation was that there was first an invasion of a micro-parasite from without, and that this underwent local multiplication, or perhaps a toxin was formed, and then internal absorption into the circulation and generalisation from within outwards.

The moral was that every effort should be made, both to get rid as soon as possible of the beginnings of disease, and that in a recurrent disease like psoriasis it was not sufficient to remove the bulk of the eruption, but efforts should be made to clear up every remnant of it.

DR. J. MOUNT BLEYER has issued a brochure on "Light: its Therapeutic Importance in Tuberculosis as Founded upon Scientific Researches."

Clinical Records.

CANCER HOSPITAL.

Dermoid Cyst of Right Ovary, Adherent Appendix, and Cystic Degeneration of the Left Ovary.

Under the care of F. BOWREMAN JESSETT, F.R.C.S.

A. C., æt. 32, admitted into the Cancer Hospital, January 7th, 1903, complaining of acute pain in lower part of abdomen passing to both sides and back. Discomfort was first noticed last March. Has had three children, youngest three years old; no miscarriages. Had rather sharp hæmorrhage in April and May last, and since then has suffered, more or less, from amenorrhœa. The pain complained of has gradually increased in severity for several months past. She describes it as a constant dull aching pain with frequent paroxysms of sharp pain. She has lived in India for some years, and has just recovered from an attack of dysentery, which has lasted for the last four months.

On examination of the abdomen there is distinct resistance and hardness over the lower part and especially on the right side over the appendix. On deep pressure patient complains of pain, not, however, acute. Per vaginam, a hard, irregular swelling is felt in the pouch of Douglas, slightly mobile, and extending upwards towards the right side. The uterus is quite normal in size and position.

On January 13th, I operated, making the usual incision in the median line between the umbilicus and pubes. On exploring the pelvis on right side a tumour was discovered which was very adherent posteriorly; the adhesions were readily broken down, and the tumour when drawn up through the wound proved to be a dermoid cyst of the ovary and was removed. The left ovary was found to be much enlarged and cystic, and so disorganised that I deemed it advisable to remove it also. The appendix was then discovered to be very much thickened and elongated, and had some adhesion, which evidently had been adherent to the right ovary. This was removed by passing a double ligature through its mesentery and ligaturing on each side. The stump was then touched with a drop of pure carbolic acid, and the neighbouring peritoneum carefully stitched over it with catgut.

In removing the appendix I much prefer passing a fine silk ligature around the appendix to the method often adopted of stripping and turning back the peritoneum and applying the ligature around the muscular and mucous coats only. I have found by experiment in the post-mortem room that by ligaturing the appendix in its entirety, the mucous coat is completely divided just in the same manner as the inner coats of an artery are divided after being tied.

Case of Fibroid of the Uterus with Persistent Hæmorrhage in a Patient who had had Ventro-Fixation Performed for Retroversion and Prolapsus Uteri.

This case is of interest as it is the only one in which I have had an opportunity of seeing the result of ventro-fixation. J. B., æt. 46, widow, was admitted into the hospital in January, 1901, suffering from prolapse and extreme retroversion of the uterus. No pessary was of any use, and as she was suffering much pain and discomfort, I determined to perform ventro-fixation. The result was everything that could be desired, but in July, 1902, in my absence, she came under the care of Mr. Leaf, suffering from menorrhagia and endometritis. Mr. Leaf dilated the cervical canal and curetted the uterus in August. She appeared to derive a certain amount of benefit from the operation, but still lost a great deal at her periods. On my return from my holiday I found her very anæmic and complaining of pain referred to the uterus. On examination there appeared to be a good deal of uterine catarrh, but the sound passed a normal distance, and the uterus was in a good position. I had her placed under ether and again dilated and thoroughly explored the uterus, but could find no sign of a polypus to account for the hæmor-

rhage. I swabbed the whole uterine cavity freely with fuming nitric acid, being careful to neutralise any excess by application of soda bicarb. solution. She appeared to derive a great deal of benefit from this, the next two periods being not at all excessive. In December, however, she had an alarming flooding which lasted some days, and was with difficulty controlled by administering ergotin hypodermically and plugging the uterus with gauze soaked in adrenalin. This left the patient in a very exhausted condition, and I determined, directly her state would permit, to remove the uterus. This I did about a fortnight later.

I made an elliptical incision around the old scar, and opened the abdomen, expecting to find the uterus firmly attached to the parietes. Such, however, was not the case, the attachment of the uterus to the parietes entirely by means of adhesions some half-inch to an inch long, as you will see in the specimen. There were also a few adhesions to the omentum. The uterus was readily removed. On cutting it open an interstitial submucous fibroid was found occupying the fundus, and was, of course, the source of the hæmorrhage. The patient has now made a perfect recovery.

It is interesting to notice these adhesions, as in the operation in which I performed ventro-fixation I fastened the uterus with Chinese gut sutures which were passed through the peritoneum, fascia, and muscular tissues of the parietes, and I fully expected to find the uterus firmly adherent. In the condition in which it really was there would have been nothing to interfere with pregnancy should it have occurred, in fact, there was nothing more or less than an artificial peritoneal ligament, sufficient to prevent retroversion again occurring, but not sufficient to prevent the free mobility of the uterus, and certainly in a case of complete prolapse it would not have prevented a recurrence of the prolapse. I should be glad to hear if any other Fellow of the Society has had an opportunity of seeing the results of a similar operation performed by him. There are many cases recorded in which women have become pregnant after ventro-fixation, and gone the full period without any inconvenience being experienced; possibly the conditions were the same as in this case.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 12TH, 1903.

Dr. HEYWOOD SMITH, President, in the Chair.

THE PRESIDENT mentioned that the Council of the Society, anticipating the feelings of the Fellows generally, had already written a letter of condolence to Mrs. O'Callaghan upon the lamented death of her husband, Mr. Robert O'Callaghan, one of their earliest Fellows and a frequent and esteemed contributor to the proceedings of the Society.

Dr. H. MACNAUGHTON-JONES read notes of two instances of

CYSTS OF THE INGUINAL CANAL

connected with the round ligament, which will be found on page 186.

Mr. F. BOWREMAN JESSETT showed a "Dermoid Cyst of the Right Ovary with Adherent Appendix," also a "Fibroid Uterus," removed for persistent hæmorrhage after a previous ventro-fixation for retroversion and prolapse, the notes of which appear under the heading of "Clinical Records," on this page.

THE PRESIDENT said that when the ovary was the seat of much inflammatory mischief, even in the beginning of cystic disease, the menstrual flow was increased. Mr. Jessett mentioned that the dermoid tumour had been associated with amenorrhœa and dysmenorrhœa; it would be of interest if any other Fellow had found the flow to be diminished in dermoid cases also, or in any other special form of ovarian disease. Dr. Garrett Anderson would perhaps tell

them in regard to the extension of the adhesions after ventro-fixation, what Dr. Howard Kelly's attitude towards that operation was at present.

Dr. L. GARRETT ANDERSON said that while in Baltimore last year she had had the advantage of seeing a large number of cases treated by Dr. Howard Kelly. She could not remember any instance of abdominal section some time after a previous fixation, but Dr. Kelly often referred to cases in which he had had an opportunity of studying the condition of the uterus and its adhesions after ventro-fixation, and, in many, the adhesions, as remarked by the President, had stretched to a considerable extent. Dr. Kelly's practice now was to fix the uterus to the peritoneum only, and not to the whole thickness of the abdominal wall, and he had quite given up passing the sutures through the posterior surface of the uterus.

Dr. MACNAUGHTON-JONES referred to the case he had brought before the Society last April in which, more than two years after a ventro-fixation, he had had to open the abdomen a second time to remove an ovarian cyst as large as an orange, the patient, in the interval, having had a miscarriage, and also borne a healthy child at term after a difficult labour with a transverse presentation. Mr. Ryall had assisted him at the second operation, and they had found the attachment of the uterus to the abdominal wall about an inch and a half long and similar to those depicted by Howard Kelly. Hardly anyone would now perform ventro-fixation on a woman capable of child-bearing; suspension was a different matter, but the operation just referred to by Dr. Garrett Anderson and well known as Howard Kelly's, was not, in his (Dr. Macnaughton-Jones) opinion, theoretically as perfect as Olshausen's method of doubling the round ligaments and attaching them to the sub-peritoneal fascia.

Dr. F. A. PURCELL mentioned that he had at present in hospital a woman whose uterus he had fixed to the abdominal wall by passing sutures through the round ligaments on both sides. The uterus was suspended in good position, but she had developed a sinus or abscess which would not heal, and he had not been able to find and extract the ligatures.

Mr. JESSETT, in reply, thought the case he had described demonstrated that ventral suspension would be of very little use in prolapse of the uterus; that the prolapse had not recurred was due to the fact that the utero-sacral ligaments had been shortened at the time of the operation. Mr. Greig Smith had shown that firm union could not be obtained between two peritoneal surfaces, and to perform ventro-fixation properly it was indispensable to fix the uterus to the muscular tissue of the abdominal wall.

The PRESIDENT then delivered his Inaugural Address: Even in the seventies a want had been felt for a society whose main object should be the study of the diseases of women and their treatment, operative and otherwise. In 1884 this feeling became more acute, and it was recognised that the advancement of scientific knowledge would in such a society be best promoted if the exhibition of specimens and the reading of clinical cases were given precedence of more formal papers, and if a Journal were published which should be not merely a record of the proceedings of the society, but should represent the progress of gynecology throughout the world. After consulting many of the leading gynecologists of the day, he had at their request convened a meeting in December, 1884, at which Dr. Routh presided, and a large number of representative men were present. The British Gynecological Society was launched, Dr. Robert Barnes, happily still with them, accepted the position of Honorary President, and Sir J. Halliday Croom, their late President, was a member of the first council elected. In a comprehensive review of the proceedings, and of the original articles published in the *Journal*, the President pointed out that by far the larger part of the work done by the society, work that gave rise to important discussions, and by means of which gynecology

had been greatly advanced during the past eighteen years, had consisted in the exhibition of specimens, nearly all of which were brought from operations, recent or otherwise, very few being the result of necropsies. Of the 234 meetings held by the society, no less than 40 were entirely devoted to the exhibition of specimens and reading of clinical cases, and altogether 738 specimens had been shown, of which 243 were fibroids, many complicated by displacements, pregnancy, cancer, and cystic or other forms of degeneration. In the removal of fibroid tumours, up to the year 1894, clamps or the *serre-nœud* were almost invariably employed, but since that date the prevailing method had been sub-peritoneal hysterectomy, and he congratulated the society on the share they had taken in promoting the adoption of the improved method of treating the stump. Most of the ovarian specimens, of which they had had 140, were exhibited in the earlier years, and this was no doubt because ovariectomy had come to be regarded as an obligatory operation and not one of election; no ovarian tumour was now left to develop to an inconvenient or dangerous size, and probably only the rarer forms were now brought before the society; of these they had seen 26 dermoid and 19 malignant growths, and 14 instances of twisted pedicle. He desired to draw particular attention to the light the society had thrown on ectopic pregnancy by the reading of nine papers on that subject, the narration of ten cases, three original communications to the *Journal*, and 36 actual specimens shown, the removal of which had undoubtedly saved many lives. Sir Halliday Croom had lately impressed upon them that there was medical, as well as surgical, gynecology, and Dr. Cullingworth had, in his Bradshaw Lecture, in weighty words insisted that the fact that gynecology was becoming inevitably more surgical was all the more reason that medicine should still keep a hold upon it, to exercise a wholesome restraint upon its surgical enthusiasm, and to continue to inspire it with that reverence for accuracy of diagnosis which otherwise it might be apt to lose. The enormous mass of material laid before them was a proof of the vast importance of surgical methods in relieving the diseases of women, but in estimating that importance they must not forget that though in medical gynecology, so-called, there was doubtless much minor surgery, medical methods afforded no "chips from the work-shop" for exhibition. Their work had, he believed, taught them that it was not the most anomalous cases that shed most light upon any form of disease, and that each Fellow should bring forward any case that might show the advantage, or otherwise, of any special treatment. It would, he thought, be profitable occasionally to devote evenings to the discussion more particularly of medical treatment, and to encourage Fellows in private practice to bring forward cases presenting difficulties in differential diagnosis. There were still vast fields of research open to diligent investigation: he might instance the physiology of menstruation and the etiology of cancer, and as subjects demanding the attention of the society he indicated the early diagnosis of tubal pregnancy with a view to the prophylaxis of rupture, the question of removing the cervix only in cervical cancer, the relative advantages of sub-peritoneal and total hysterectomy, and whether, with the uterus, one should remove one ovary, or both, or neither. The lack of any criterion for the efficiency of nurses, especially in gynecological work, had long been felt by the profession, and a committee appointed by the council having gone thoroughly into the matter and conferred with delegates from the Matron's Council, it had been decided to institute examinations and grant certificates in monthly and gynecological nursing; but no woman will be eligible for the society's examination unless she has had three years' training in hospital work. A Board of Examiners, of which the President of the society is *ex officio* a member, had been appointed, and examinations would be held once a quarter. By employing such certificated

nurses, medical practitioners will have a guarantee of the assistance of women well qualified for their work, of good character, and amenable to the rules of professional ethics.

Dr. C. H. F. ROUTH said that looking at the amount of useful work the society had been able to do, and the advantage it had been to all who had joined it, it was hard to realise the contempt that was formerly shown to gynæcology, and those who practised it, by other members of the medical profession. He could well remember the time when an eminent man spoke of gynæcologists at a well-known medical society as persons to be avoided, and exhibited a sound as an instrument fit "to frighten a corpse." He even spoke of an ovariectomy performed at the Samaritan Hospital by Mr., afterwards Sir, Spencer Wells, as "a horrible sight." But gynæcology had won its way to the infinite advantage of womenkind and their offspring. There had been great improvement in nursing; he could remember that formerly a patient, so far from having a bath when admitted to a hospital, was not even washed before operation, which was performed, as a rule, in the patient's bed. There was, however, room for further improvement, and he thought that the inauguration of examinations and granting certificates would assist in bringing it about, and be of great advantage. He proposed that the thanks of the society be given to the President for his able address.

Mr. BOWREMAN JESSETT seconded the motion. The interesting epitome the President had given them of the work of the society during the eighteen years of its existence must have entailed an immense amount of arduous work, for which the Fellows were very grateful; they were to be congratulated upon having Dr. Heywood Smith in the chair; and he had no doubt that his year of office would be a very prosperous one for the society.

Dr. MACNAUGHTON-JONES said that the President had, with characteristic modesty, omitted any mention of his own influence upon the development of hysterectomy, but it was well known, not only in the society, but on the Continent and in America, that Dr. Heywood Smith had been the very first in the United Kingdom to advocate the sub-peritoneal treatment of the stump in the removal of the uterus. Not only had Dr. Heywood Smith been a prime mover in the foundation of the society, but there had not been any discussion at any of its meetings, of importance, in which he had not taken part. His sincere personal regard made it a great pleasure to him to support the motion. Dr. Heywood Smith's year of office would, he was sure, be a source of pride to the society.

The motion was then put by the last speaker, and carried with acclamation.

SOCIETY OF ANÆSTHETISTS.

MEETING HELD FEBRUARY 6TH, 1903.

Mr. WALTER TYRRELL, L.R.C.P.Lond., M.R.C.S.Eng., in the Chair.

Mr. TYRRELL, referring to the case of death following an administration of nitrous oxide gas, a newspaper report of which he read at the last meeting of the society, said that on investigation he had found it to be a death not from the gas but from acute ammonia poisoning, strong ammonia having been held to the nostrils of the patient for about ten minutes after the administration by the dentist who had administered the gas, as the patient did not seem to be recovering in the usual way. The case was removed to hospital, and died some eighteen hours after the administration.

Dr. J. BLUMFELD read a paper on "The Relation of Anæsthetics to Shock," which will be found on page 185.

In the course of the discussion which followed, Mr. CURTIS said that if the perforation were doubtful and an exploratory operation were undertaken, he preferred local analgesia; but if the perforation were undoubted, then a general anæsthetic was much to be

preferred, and he merely suggested local anæsthesia as a compromise in those cases where it was thought that a patient ought to have the benefit of the doubt of an exploratory operation, but where the intrinsic risk of a general anæsthetic had to be avoided. In his opinion the question depended upon the patient himself; if very nervous, then a general anæsthetic was to be preferred; but some patients whom one might expect to prove troublesome often proved very satisfactory. He had seen Cæsarian section done under local anæsthesia with no pain or trouble except when the vessels were caught in the clip forceps.

Mrs. DICKENSON BERRY and Miss ALDRICH BLAIKE said that they had seen many operations for goitre performed under local anæsthesia without any symptom of shock.

Mr. CROUCH said that he was absolutely of opinion that shock was far more likely to supervene under light than under deep anæsthesia, that his practice was to push the anæsthetic to its fullest extent, and he taught that fall of blood-pressure from chloroform was much less dangerous than fall of blood-pressure from shock.

Dr. LOW said that he constantly observed that when the fear of the operation, which causes symptoms of shock, was removed by the administration of an anæsthetic, the patient's condition markedly improved, and the symptoms of shock disappeared; this was especially the case under ether.

Mr. TYRRELL said that after an experience of twenty-five years he felt that there were cases in which shock was produced under light anæsthesia and also cases in which the shock was more marked under profound anæsthesia, the fact being that they all had to use their judgment and treat each case on its own merits, and that there never could be any hard and fast method of administration which would suit all cases. Mr. Tyrrell cited cases illustrating this view, which had recently occurred in his own practice.

Drs. Collingwood, Bakewell, Norton, and Probyn-Williams also spoke.

Dr. MAUGHAN then reported a case of death following the administration of nitrous oxide. This was a young woman who was suffering from tonsillitis, but in whom the constitutional symptoms were marked and the pulse-rate out of all proportion to the physical signs. Dr. Maughan administered nitrous oxide as the patient would not allow him to incise the tonsil without an anæsthetic. The patient was placed in an easy chair in her nightdress, with a prop between the teeth. Anæsthesia was quickly induced to the stage of loss of light reflex, two breaths of air having been given with the gas. At this point the face-piece was removed, but precisely at this moment the patient was observed to have stopped breathing. She was immediately placed on the floor with the forceps upon the tongue, Howard's method of artificial respiration was tried for about fifteen seconds, ammonia being held to the nose meanwhile, but no air entered. No further time was lost, and Dr. Maughan promptly performed laryngo-tracheotomy, when a full deep inspiration was taken, the lips and cheeks quickly returning to their normal colour. The corneal and conjunctival reflexes were, however, absent and never returned. The radial pulse was small, quick, and barely perceptible, the respirations about twelve per minute, and so continued for twenty minutes, when the intervals began to enlarge and the inspirations to shallow. The breathing became more and more irregular during the next ten minutes, when the patient died, the pulse during the last ten minutes of life becoming imperceptible at the wrist, although heart sounds could be heard up to the last moment. The post-mortem examination revealed nothing beyond extensive angina Ludovici, and some oedema of the glottis. The mitral orifice of the heart was rather smaller than normal, but there was no evidence of structural damage either recent or remote. Dr. Maughan was at a loss to explain the cause of death, since the tracheotomy prolonged life for nineteen minutes. He therefore asked

for the opinion of the society. He regretted that he had not used a local or a very light chloroform anæsthesia, but he thought that in a rapidly progressive disease of this kind affecting the respiratory organs no anæsthetic could be deemed harmless.

Dr. PROBYN-WILLIAMS agreed that in cases of this nature gas was certainly not harmless; but in this case he could not see that the death was due to the gas, since the patient lived for nineteen minutes after the administration was stopped and the air was rendered clear by the operation of tracheotomy.

Dr. Low related a similar case in which he had been called upon to give chloroform. He was using the lightest possible degree of anæsthesia, but the patient got so bad that he stopped the administration, and the patient recovered sufficiently to be able to answer questions, only to die a few moments later. He pointed out that if this patient had not spoken the death would have been attributed to the chloroform.

The PRESIDENT agreed that the case could not be attributed solely to the anæsthetic, and there was no doubt that these acute cases of septic throat died very suddenly. He could not see what more Dr. Maughan could have done for the patient. He thought that probably the true explanation was that the patient died of heart failure due primarily to the septic infection, but hastened by the anæsthetic, the strain thrown upon the heart from the right-sided engorgement being just too much for it to cope with in its condition of septic poisoning, although such strain would have no effect on the same heart in a condition of health. The best thanks of the society were due to Dr. Maughan for bringing this very instructive case before them.

THE OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

The President, DR. URBAN PRITCHARD, in the Chair.

At a meeting held on Monday, February 2nd, a discussion took place on
TUBERCULOSIS OF THE EAR, THE NOSE, AND THE NASOPHARYNX.

Papers opening the discussion were read by Dr. Wyatt Wingrave, Dr. Jobson Horne, and Dr. William Milligan.

Dr. WYATT WINGRAVE read a report upon "The Microscopical Examination of the Discharge in One Hundred Cases of Middle Ear Suppuration, with an Analysis of the Results, having Special Reference to the Presence of Tubercle and 'Acid-fast' Bacilli." He arrived at the following conclusions:—That acid and alcohol-fast bacilli are demonstrable in a large proportion of chronic purulent ear discharges. That in seventeen cases they were presumably tubercle bacilli, in so far that they conformed to the recognised morphological and staining characters, and were for the most part associated with reliable clinical evidence of tuberculosis. That in seven (pseudo-tubercle bacilli) cases, while conforming in a greater or less degree to the staining requirements, they were morphologically unlike tubercle bacilli, yet five of them had either a family or personal history of phthisis. That success in their demonstration in a great measure depends upon the methods of collecting and staining, together with perseverance in search. That in the peculiar selective action of the squames—a property specially attributed to certain bacilli—we have a possible source of error in diagnosis, and an explanation of the peculiar affinity of other bacilli for fuchsin.

Dr. JOBSON HORNE read a paper on "The Clinical Diagnosis and Surgical Treatment of Tuberculosis of the Temporal Bone, considered with reference to the Pathology and Morbid Anatomy of the Disease." The paper, so far as it related to the clinical diagnosis, after taking into account the characteristic features of tuberculosis of the ear, dealt mainly with two points: (1) The value to be attached to circumstantial evidence in the absence of positive proof of the nature of the disease,

and (2) the necessity for discriminating between primary and secondary infection of the ear. The surgical measures, and the limitations to be put upon such measures, were to be decided by ascertaining this second point. Caution was expressed against regarding suppurative disease of the middle ear, occurring in a tuberculous subject, as necessarily tuberculous in nature. It was held that the detection of the *Bacillus tuberculosis* was the only proof positive of the disease being tuberculosis. The existence of a group of "acid-fast" bacilli, other than the *Bacillus tuberculosis* did not invalidate the microscopic diagnosis of the disease, provided the ordinary requirements of bacterioscopic technique were complied with. Negative evidence was of no value; failure to detect the *Bacillus tuberculosis* did not prove the disease to be non-tuberculous. The difficulty in detecting the bacillus in the discharge was discussed. A theory was advanced which would at once explain both this difficulty and a well-known clinical feature of the disease—absence of pain—and also the correlation of these two clinical phenomena. The theory was based upon the facts, demonstrated by Drs. Bullock and Macleod, that the "acid-fast" property was due to a wax-like body in the bacillus and not to a fat, and that the wax when broken up set free an alcohol, which was an essential factor in the staining property. It was suggested that the decomposition of the wax was accountable for the difficulty in detecting the bacilli, and the resulting product possessed anæsthetic property. The differential diagnosis between the primary and secondary infection could be made partly by the exclusion of tuberculosis existing in other organs, but more particularly by the condition of the gland adjacent to the affected end; in the primary infection the glands were more often and more extensively involved. As regards treatment, the surgical ablation of disease secondary to pulmonary disease was to be avoided, but in the primary form it was to be undertaken by removing in the first instance the infected gland; the possibility of the occurrence of a blood infection, and of death from miliary tuberculosis, was to be kept in view.

Dr. W. MILLIGAN read a paper on the "Diagnosis and Treatment of Tuberculous Disease of the Middle Ear and its Accessory Cavities." The conclusions he arrived at were as follows:—(1) That in all cases of middle-ear disease of suspected tuberculous origin search should be made for tubercle bacilli, either in the discharge, in tufts of exuberant granulation tissue, or in enlarged periotic glands. (2) That inoculation experiments (either subcutaneous or intra-peritoneal) afford a ready and reliable means of proving or excluding the tuberculous nature of the disease. (3) That a final and exact diagnosis is imperative, both from the point of view of prognosis and of treatment. (4) That tuberculous disease of the middle ear and accessory cavities is a frequent disease among infants and young children. (5) That the disease is most frequently found as secondary to tuberculous processes in other regions of the body. (6) That primary tuberculous disease of the middle ear is probably of more frequent occurrence than is usually supposed. (7) That the prognosis is always grave, but that in a certain proportion of cases suitably planned surgical intervention will eradicate the disease. (8) That in many cases it is advisable to conduct the operative treatment "in stages." (9) That when less than 10 per cent. of hearing power remains no attempt should be made to preserve the organ as an organ of special sense. (10) That when more than 10 per cent. of hearing power remains in a patient, in otherwise approved health, a definite attempt should be made to preserve what amount of hearing power still exists. (11) That where the tuberculous origin of the disease has been scientifically demonstrated the case should be regarded as infectious, and precautions taken accordingly.

The PRESIDENT remarked that the theory put forward by Dr. Jobson Horne did not quite get rid of the chief cause of the pain, namely, pressure on nerve endings.

In tuberculous cases there was not very acute inflammation, not very great pressure, and therefore absence of acute pain. In selecting cases for operation he thought the important point was not the amount of local damage, but the general condition of the patient.

Mr. C. A. BALLANCE thought tuberculosis of the temporal bone region should be treated and thought of, both pathologically and surgically, exactly as tuberculosis of any other bone was. He agreed that where the lesion was extensive the operation should be done by stages. He believed that in a considerable number of cases the temporal bone was the seat of the primary disease, and it was in these cases, if the primary focus were entirely ablated, the surgeon was very likely to be able to deal with the secondary focus. He referred to two remarkable cases in which tuberculous disease of the temporal bone was successfully treated by him, in both of which cases surgeons had removed in previous years glands from the neck which were tuberculous, but the disease in the temporal bone had been left. Mr. Ballance felt sure it was the primary source of the disease which it was the surgeon's duty to attack at the earliest possible moment, and that it should be removed completely without regard to the facial nerve.

Mr. A. E. CUMBERBATCH considered it should not be a question of operating upon them simply because they were tuberculous. The question was whether it was possible to remove the disease. If so, it should be done.

Dr. H. I. WHITEHEAD referred to a series of records of fatal cases of ear disease occurring in the clinique to which he was attached. Of the last 100 cases there were only twelve which were distinctly tuberculous, and of these all but three were under two years of age. Of the three over that age all had advanced tuberculous mischief elsewhere, chiefly in the lungs. Of the nine cases under two years of age, in only one was there another focus of infection, *i.e.*, in eight of the cases the disease was apparently primary in the temporal bone. Two of the eight died, apparently from military tubercles of the meninges only. Of the others, six, or 50 per cent. died of general military tuberculosis.

Dr. HUGH JONES said it was worthy of consideration whether bovine tuberculosis might not be responsible for the primary mastoid affections. It has recently been suggested that it was accountable for primary bone and joint affections. It should make one alive to the question of the milk supply.

Mr. A. CHEATLE remarked that many times in young children with profuse discharge from the ear, which was suspected to be tuberculous, the smell had been characteristic. He agreed with the President that painlessness of tubercle in the middle ear was due to the fact that there was no tension, and that there was not much inflammation, and therefore little pressure in the nerve endings; that was quite sufficient to explain the comparative absence of pain.

The discussion will be resumed on March 2nd, at 4.30 p.m.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FEBRUARY 20TH, 1903.

DR. EDMUND CAUTLEY in the Chair.

Mr. H. J. CURTIS showed a specimen of "congenital periosteal sarcoma" which apparently sprang from the acromion process of the left scapula of a boy, from whom it had been successfully removed at the age of 5½ months. At birth it was the size of a small hen's egg. It was a mixed spindle- and round-celled growth.

Dr. G. A. SUTHERLAND showed a child, *æt.* 5, with marked "ataxy," which had been present from the time he commenced to walk. He considered that possibly the condition might be due to a congenital cerebellar lesion. The superficial and deep reflexes were normal. There were no changes in the fundus oculi or paralysis of the ocular muscles.

Dr. FLETCHER BEACH considered that since the labour had been a difficult one, the possibility of a cerebellar hæmorrhage could not be excluded.

Dr. JAMES TAYLOR, although he agreed in some respects with Dr. Beach, nevertheless considered it possible that cases similar to those described by Marie, which manifested themselves later on in life, might occasionally occur in children at this early age.

Dr. SUTHERLAND replied.

Dr. JAMES TAYLOR showed a case of well-marked "achondroplasia" in a child, *æt.* 8. She was the seventh child, the others being healthy. She presented a characteristic deformity of the head, the humeri and femora were remarkably short, and trident-like hands were present. Her intelligence was not defective. As is frequently the case, her weight was excessive for her size.

Dr. EDMUND CAUTLEY thought the condition should be kept distinct from foetal rickets, and remarked that it had been suggested the condition might be due to osteo-myelitis.

Dr. TAYLOR, in reply, referred to a similar disease in some animals.

Dr. A. MORRISON showed a case of "Raynaud's disease" in a boy, *æt.* 8, which first manifested itself at the age of 4½ years. He did not suffer from hæmoglobinuria, and there was no evidence of congenital syphilis. Some of the attacks, as in the present case, were attended by the presence of blood-filled bullæ. Examinations of the patient's blood showed nothing abnormal.

Dr. BEACH mentioned a case in which a successful result had been obtained by the use of Esmarch's bandage.

Mr. GEORGE PERNET called attention to the fact that scleroderma and sclerodactylia might follow Raynaud's disease.

Dr. THEODORE FISHER mentioned a case in which a condition similar to that of Raynaud's disease appeared in one hand as a sequence to a blow. He thought a strong peripheral stimulus might induce central nervous disturbance.

Dr. LEONARD GUTHRIE thought the child syphilitic. He was also of opinion that paroxysmal hæmoglobinuria and Raynaud's disease were syphilitic manifestations.

Dr. TAYLOR could not accept Dr. Guthrie's dictum that hæmoglobinuria and Raynaud's disease were necessarily syphilitic.

Dr. CAUTLEY agreed with Dr. Taylor, but referred to a case of symmetrical gangrene which quickly responded to anti-syphilitic treatment.

Dr. MORRISON replied.

Dr. LEONARD GUTHRIE showed a slightly rickety infant, *æt.* 2, whose ligaments were unduly lax and whose muscular system was wanting in tone. He could not make up his mind whether it was in the nature of rickets or of a congenital defect or want of development.

Dr. SUTHERLAND considered it a case of rickets in which the stress had fallen upon the ligaments and muscles rather than any special congenital defect.

Dr. CAUTLEY suggested that the condition was one of mal-development rather than rickets.

Dr. GEORGE CARPENTER read a paper on four cases of

HEART DISEASE,

two of which clinically could have been mistaken for mitral valvular disease. In one a presystolic murmur was present, suggesting mitral stenosis. In three of these cases after death the valves and pericardium proved healthy, but the hearts were hypertrophied and dilated, and disease of the myocardium was present. In the fourth case, one of heart failure following diphtheria, in which a mitral murmur was present associated with a pulsating liver, complete and rapid recovery took place with disappearance of the murmur.

Dr. A. E. SANSOM commented upon Dr. Carpenter's cases. He thought the subject of myocarditis required further investigation, and that clinically at present it is almost impossible to diagnose such affections of the heart muscle, seeing that not only mitral systolic

bruits but presystolic murmurs also were present in such cases.

Dr. FISHER expressed his interest in Dr. Carpenter's observations, and referred to his own pathological experience of complicated myocarditis. He also commented upon the presence of presystolic murmurs in cases in which there was neither mitral stenosis nor aortic valvular disease. Dr. CARPENTER replied.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, FEBRUARY 12TH, 1903.

RUSHTON PARKER, B.S., F.R.C.S., President, in the Chair.

Mr. EDGAR STEVENSON showed a case of "Congenital Glaucoma in a Child, *æt.* 5," and described in detail the etiology and pathology of the condition. The patient presented all the typical appearances, the eyes being uniformly enlarged, with the cornea 18 mm. in horizontal diameter. The optic discs were cupped and atrophic, and the visual fields much contracted. Out of 65,000 patients seen in recent years at the Eye and Ear Infirmary, the disease had appeared four times.

Dr. Grossmann and Mr. E. G. Lee commented upon the case.

Dr. J. E. McDougall showed a case of "Adherent Soft Palate," which had been successfully treated by a new method. A thin plate of metal was attached to the patient's artificial tooth-plate, and to the extremity thereof a tube was soldered. The tube was passed through an opening in the soft palate made to admit its passage. Healing had taken place, and the edges had become covered with epithelium. The patient removed and replaced the arrangement as readily as she did the ordinary tooth-plate before any addition was made to it. When no tooth-plate was worn, a carrier for the tube could be fixed to the teeth. The apparatus gave no trouble, and the result was most satisfactory. Nose-breathing was carried on comfortably, the sense of smell had returned, and that of taste had regained its full value.

Dr. Philip Nelson spoke.

Mr. HAWKINS-AMBLER read a note on "Chorio-epithelioma Malignum." He thought Marchand's work had proved the origin of the growth from the whole of the epithelial covering of the chorionic villi. Mr. Hawkins-Ambler gave in detail the history of a woman, *æt.* 39, the mother of twelve children, who had suffered from the disease. The last of three abortions occurred in May, 1900, and was accompanied by severe hæmorrhage. The uterus was curetted and packed. Six weeks later she had furious bleeding, the uterus was again packed, and subsequently thoroughly scraped with a sharp spoon. The uterus was smooth, and measured 3 ins. On June 17th, 1902, a uterine swelling was present extending to within 1½ ins. of the umbilicus. There was a steady chocolate-coloured discharge, and the patient was anæmic and breathless. No radical treatment was possible. No regular post-mortem was obtained and no metastatic growths were found. The case was interesting owing to the long interval since the last pregnancy, and the thorough curettage then done. Packing with gauze and adrenalin solution had been less effective than with gauze soaked in hamamelis extract.

Mr. F. T. PAUL read a short paper on "Colotomy and Colectomy." He considered the former operation was becoming more popular, chiefly owing to the better artificial anus now generally obtained. In regard to the latter he still strongly advocated bringing the ends of the bowel out, with subsequent restoration of continuity, in preference to end to end union. The latter was more satisfactory to the surgeon when his patient recovered, but the risk was much greater. Patients illustrating the results of the operations were shown, and also the plug and belt used by Mr. Paul for colotomy cases.

The President, Sir Wm. Banks, Drs. Alexander Briggs, and Heatherley, and Mr. Monsarrat spoke, and Mr. PAUL replied.

CORK MEDICAL AND SURGICAL SOCIETY.
MEETING HELD ON WEDNESDAY EVENING, FEBRUARY 11TH.

Dr. P. T. O'SULLIVAN, President, in the Chair.

Dr. W. ASHLEY CUMMINS showed a young woman, *æt.* 21, suffering from "congenital spastic paraplegia." The patient did not look more than about fourteen years of age. The paraplegia was not complete, the patient being able to walk a little with assistance, or by holding a chair or table. The knee-jerk was excessive, and there was marked adductor spasm, the inner sides of the knees rubbing against each other in walking. There were no sensory symptoms or bladder trouble. The upper extremities were very small, but were otherwise unaffected. The mental development was fair.

Dr. T. GELSTON ATKINS showed a man, *æt.* 27, on whom he had performed "nephrectomy" for hydronephrosis due to stricture of the ureter, probably congenital. The symptoms were unilateral lumbar pain followed by hæmaturia. The urine contained a small quantity of albumen, but no pus. By the use of Harris' urine segregator it was easy to determine the affected kidney. The symptoms pointed to stone. The patient made a good recovery. The kidney was shown, and the pelvis was greatly enlarged. Dr. Atkins also read notes of a case of "nephrectomy for cystic disease of the kidney" on a woman, *æt.* 43, who suffered from lumbar pain, dysuria, and hæmaturia. The cystoscope showed cloudy urine flowing from the right ureter, which had everted and swollen edges, while the urine flowing from the left ureter was clear. The affected kidney showed an immense number of small cysts, and was much enlarged. The patient made a good recovery.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 21st, 1903.

At the meeting of the Medical Society on the 14th inst. Hr. v. Hausemann gave an address on

FOOD TUBERCULOSIS.

At the opening of his address he drew attention to Virchow's doubts as to the identity of bovine and human tuberculosis. The subject had more especially come to the front since Koch's address at the London Congress on Tuberculosis, and since that time experiments of all kinds had been made. At the last Congress in Berlin, in a discussion, Koch had thought it proper to separate the transmissibility of the disease from the cow to the human subject and the reverse transmissibility, that from man to cattle. But, as a matter of fact, a number of well-known and impartial investigators had succeeded in transmitting human tuberculosis to animals. Both diseases must therefore be identical, otherwise one would be compelled to assume that the human being from whom the virus was taken was already suffering from bovine tuberculosis.

The speaker could not recognise the justifiability of Koch's requirement that every other mode of infection must be excluded, and he also denied the correctness of the comparison between tuberculosis on the one hand and typhoid or flesh poisoning on the other.

He pointed out that if a number of people were exposed to infection from one of the latter poisons the majority of them took the disease, whilst food tuberculosis was rare, although the opportunity to acquire the disease was frequent. In the former case the disease was acute, but in the latter chronic. The speaker understood by the term food tuberculosis that form of tuberculosis in which, from the condition met with, the infection had started

exclusively from the digestive tract. In seven years he had collected twenty-five such cases, and had divided them into the following groups :

(a) Exclusive intestinal tuberculosis, no tubercle having been present anywhere else. These cases (four in number) were people who had died from other diseases, and the discovery was mostly accidental. These pure intestinal tuberculosis either healed up and left more or less considerable visible cicatrices, or they attacked the mesenteric glands or the peritoneum rapidly.

(b) The tuberculosis had attacked the mesenteric glands or the peritoneum, the other parts of the body being free.

(c) Tubercle was present in other organs, but in such only as could not offer portals of entry, for example the pleura with intact lungs, the pericardium, the meninges, &c.

(d) Other organs were affected, but here the tuberculosis was fresh, whilst in the intestine there were old ulcers.

All these cases showed that pulmonary phthisis never arose from food tuberculosis, a fact that had been confirmed by observations of other authors.

The speaker then turned to the question whether tubercle bacilli could pass through intact mucous membrane. He believed this was not possible. It was not necessary that there should be any tuberculous changes at the spot, but there must have previously been at least some slight lesion or erosion or the like.

As concerned the individual parts of the neck, tuberculous affections of the mouth and tonsils were not so rare, tuberculosis of the œsophagus rare and primary tuberculosis of it had scarcely ever been observed. The same with the stomach. That primary intestinal tuberculosis occurred with comparative rarity was due partly to the fact that not all were disposed to it. He had ascertained that of forty children under 10, with cavities opening into the bronchi, and who were too young to expectorate thoroughly, and who must therefore have swallowed the tubercle bacilli, only sixteen of them had intestinal tuberculosis. For tuberculosis to arise, the disposition thereto was also indispensable. Out of 250 people who during seven years had been engaged with himself in autopsies, only four had acquired skin tuberculosis from the pursuit, although all had been equally exposed to the danger of it. In conclusion, the speaker summed up that food tuberculosis was a rare disease ; it might heal up, or progress, but it never led to tuberculosis of the lungs.

Hr. M. Wolff showed guinea-pigs that he had infected by feeding partly with human sputum, partly with *Perlsucht* material. In some, after killing, there was no disease of intestines, although there was tubercle of the spleen, liver, kidneys, and lymph glands, in others follicular swellings or tuberculosis of intestines. He was of opinion that in making sections the intestine was not examined carefully enough, or tubercle or vestiges of it would be found more frequently. Otherwise, one would have to assume that bacilli could really penetrate intact mucous membrane without leaving a trace behind.

Hr. B. Fraenkel had even, in pre-bacillary research times doubted the identity of *Perlsucht* and human tuberculosis. Otherwise, even primary tuberculosis of intestines would often be met with in children at the breast. That "feeding" tuberculosis took place was certain, but it was questionable whether it could be set up from cattle in the human subject. Tuberculosis of the intestinal tract was not always "feeding" tuberculosis ; there were other ways of infection.

Hr. A. Bajinsky said that primary tuberculosis of the mesenteric glands being as rare as primary intestinal tuberculosis in children, the assumption of recovery from intestinal tuberculosis in childhood also fell to the ground.

Hr. Schütz had fed four calves for 230 days with

100 grms. of human sputum daily and two calves for 200 days with virulent tubercle cultures, and the six continued healthy. To other calves he gave two litres of milk from cows with tuberculous udders and these became infected partly in the intestines, partly in the mesenteric glands. Guinea-pigs were useless for experiment as they reacted equally to both poisons.

In his opinion there was a distinction between the excitator of the two diseases—human and bovine.

Austria

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 21st, 1903.

MEDIASTINAL DERMOID TUMOUR.

At the Gesellschaft der Innere Medizin Türk showed a man, æt. 57, who had fallen ill two weeks before admission to hospital with severe shivering, followed by running at the nose and cough, but no pain in the chest. On October 20th the case was diagnosed to be one of pleuritic effusion on the left side, and was admitted to the second clinic as such, although no objective symptom bore out the diagnosis. After prolonged and repeated examination the extent and appearance, with the slight subjective disturbances and no continuance of fever, led finally to some doubt. The history was gone into afresh, and the diagnosis again conjectured to be thickened pleura, with adhesions. In view of the persistence of the supposed effusion other conjectures were hazarded, such as interlobular exudation or possibly some complication of the mediastinal folds of the pleura with obliteration of the thoracic portion of the left side. It was also thought possible that it might be a tumour, but if so not of a malignant nature, no cachexia or other indication of exhaustion being present. The Röntgen rays revealed nothing beyond the clinical observations noted.

On November 10th it was decided to explore the region with a needle, but after six insertions in different spots only a few drops of a thick white fluid could be obtained. Under the microscope this appeared to consist mainly of large epithelial cells without nuclei, resembling the corneal cell of the epidermis but containing cholesterol crystals. The patient refused any further exploration and left the hospital, but returned again on December 16th after two days' fever and feeling generally unwell. Again he submitted to exploration, and again the squamous cells and cholesterol crystals, with a few fatty and epithelial cells, were met with. There were no leucocytes or erythrocytes, which proved that the original diagnosis was in error. It was now surmised that the thoracic dulness was due to a neoplasm composed of epithelial cells and cholesterol, and that no exudation or empyema was present. Again, it was clear that no cyst such as echinococcus existed, while the absence of leucocytes and the presence of these suspicious keratin cells, which retained the iodine colouring matter in Gram's test, were confirmatory of a morbid growth in the mediastinum.

Therapeutical measures in such a case would necessarily be limited to a surgical operation. If no operation were undertaken the history of such cases pointed to the probability of ultimate rupture of the lung or pericardium and death. The operations which have been performed have resulted favourably, and where no cysts exist the whole mass can be easily removed, allowing the surrounding tissues to contract, but not always without leaving a fistula, which must be guarded against.

ACUTE GRAVES' DISEASE WITH CHOREA.

Rudinyer showed a woman, æt. 25, whom he had under his care since the middle of November, 1902, with a large swelling in the neck, which had formed within fourteen days. After treating with iodine ointment the

tumour receded, and by the end of December the patient felt comparatively well, although much emaciated. On the last day of December, however, she became suddenly ill, and this continued to January 2nd. Her disposition, which had been happy and agreeable previously, became morose, sullen, and irritable, with a vacant expression of the physiognomy, protrusion of the eyes, and severe palpitation. There was also vomiting and disinclination to take food, although the bowels became more regular than they hitherto had been, while perspiration was very free. The patient had all the symptoms of a pulsating exophthalmic goitre. Graefe and Möbius symptoms, tachycardia (120 to 140), with a fine and constant tremor of the muscles. The skin was moist and the temperature ranged about normal.

The etiology of the disease is obscure, as the choreic addition may be due to an infective or toxic element of the morbid condition. At first it was presumed that the case was one of simple struma, but the consistence and situation were against the theory, while the symptoms of Graves' disease were against exploration.

The rapidity of the pulse and the reluctance to take food made the prognosis bad. Two grammes of bromide in 400 grammes of salt solution was given twice a day *per rectum*.

The Operating Theatres.

CANCER HOSPITAL.

VENTRO-FIXATION OF THE SIGMOID FOR PROCIDENTIA AFTER EXCISION OF RECTUM.—Mr. CHARLES RYALL operated on a woman, *æt.* 43, who had been admitted suffering from distressing procidentia from a sub-sacral anus. Four years ago he had performed excision for cancer. This was done by dorsal and median incision, when the coccyx and lower two pieces of the sacrum were removed, together with a large portion of the rectum, including the anus. In this case the posterior vaginal wall was also partly removed owing to its implication in the growth. The upper part of the rectum was freed by tying and severing its mesentery, and was brought down and made to complete the posterior wall of the vagina; the end of the bowel was also fixed beneath the sacrum to form a new anus. The patient made an excellent recovery, and was discharged wearing an anal plug. Two years afterwards she was re-admitted for procidentia, which no anal plug seemed capable of relieving, so operative measures were resorted to, and in this instance three or four inches of bowel (that is, the prolapsed portion) were excised; this gave the patient temporary relief, and she was discharged from hospital still wearing an anal plug, but in the course of time, and owing to the absence of any sphincteric support, prolapse and procidentia gradually recurred, and the patient was most anxious that something more should be done to relieve her of this trouble. Further excision was deemed inadvisable, as the last operation had failed to give the necessary relief. The extent of the procidentia now was from two to three inches in length, so Mr. Ryall suggested opening the abdomen and reducing the prolapse by traction from within. This was done through an incision in the left iliac region. The sigmoid was grasped and traction was made upon its lower portion until the trouble was reduced and the gut was fairly taut, then by means of a couple of silk worm-gut sutures passed through the middle of the longitudinal muscular band the sigmoid was attached to the musculo-aponeurotic layer of the abdominal wall; the abdominal incision was closed. Mr. Ryall said that as far as the radical operation for carcinoma was concerned this was a very encouraging case, as the disease showed no evidence of recurrence four years after operation, and although the original method adopted to eradicate the disease was

a somewhat formidable one, yet the end had justified the means. Procidentia, he remarked, frequently occurs in these cases where the sphincter line has been sacrificed, and the new anus placed beneath the sacrum, and he was now quite of opinion that further excision only gives temporary relief to this condition; he therefore thought the method he had now adopted of ventro-fixation of the sigmoid might have the desired effect, as it was found that after opening the abdomen and pulling up the sigmoid the procidentia was relieved. He pointed out that when he fixed the sigmoid in position he took care that the tension should not be so great as to cause possible obstruction. It is satisfactory to state that the patient made an uninterrupted recovery, and was greatly relieved. She left the hospital three weeks after operation, and though there was still some prolapse of mucous membrane there was no recurrence of the extensive procidentia.

THE HOUSING PROBLEM.

THE proper housing of the poor is a question that not only affects profoundly the welfare of a class, but in addition strikes deep down into the foundations of the national prosperity. In its fulfilment lies no small part of the general advance of the community towards the millennium of health and morals. From a sanitary point of view it closely concerns medical men in all parts of the United Kingdom. As a matter of fact the evils of bad housing are hardly less manifest in towns than in the country. For years past the attention of the British Medical Association has been called to that important proposition, which, indeed, so far as we know, has never been seriously disputed. In short, it may be stated that the question of the housing of the working classes is no less urgent than universal. Under such circumstances it was no small disappointment to find that in the recent

King's speech the present Government, relieved of the exacting pressure of a great war, made no proposal to discuss the housing problem during the forthcoming Session of Parliament. The second day of debate upon the King's speech, however, brought an amendment to the effect "that the greatest hardships were inflicted upon many of the working class by reason of the lack of proper housing accommodation, and that immediate Parliamentary attention to this evil was one of the most pressing of the necessities of domestic policy." Although the amendment was lost, it nevertheless drew from the Government a promise on the part of Mr. Walter Long, President of the Local Government Board, to introduce a Bill during the present Session to make certain "small amendments" which he considered possible and desirable. The main points thus conceded appeared to be the extension of time for repayment of loans by local authorities, the submitting to arbitration by a jury the price paid by a local authority for land or buildings instead of by private arbitrators, and increased facilities for acquiring possession of condemned property. Mr. Long's concessions are admittedly small, in spite of the fact that they are intended to remedy a great evil. We are inclined to agree with the contention of Dr. Macnamara, the proposer of the amendment, that although some good would be effected by extension of time for repayment of specific loans or by increasing powers of compulsory rehousing, yet after all those things merely touched the fringe of the question. The real obstacle in the way of the proper housing of the working classes in the great city undoubtedly lies in the enormous cost of land. That being the case the remedy must be found in measures that deal with the land problem. In the country we are inclined to think much of the evil of bad housing of the poor rests at the door of careless and incompetent administration by rural sanitary authorities. Mr. Long said much in support of the Local Government Board's past action with regard to the rehousing question. For many years past medical officers of health all over the Kingdom have told a different tale. The attempt to close insanitary areas and to build artisan dwellings has resulted in heartbreaking disappointment and failure, owing to the dilatory and obstructive methods of the Board. Be that as it may, the fact that his Majesty's Government has been forced into a promise of legislation upon a subject not mentioned in the King's speech affords a significant hint of the general feeling of the House of Commons. Now that the country is ripe for legislation it would be a thousand pities were the emergency tided over with stop-gap devices dealing with mere surface defects but neglecting the canker at work deep down in the core of the matter.

THE CARE OF INEBRIATES.

In 1900, the joint committee of the Richmond Lunatic Asylum called the attention of the executive to the necessity for extending the Inebriates Act, in order to provide some more effective method of

dealing with those suffering from alcoholic insanity. The committee were supported by a conference of county councils, who recommended the establishment of inebriate homes. From that day to last week the scheme was not heard of by the public, and the country is still dependent on the inadequate provision furnished by the Ennis institution. The fault for this delay lies with the executive government. Politicians prefer to deal with burning questions and to associate their names with large measures, consequently domestic legislation is much neglected, and, when touched, is treated in the least contentious manner possible. Inebriety has suffered in this way for many years past. In 1879, 1888, 1898, and 1899 it was the subject of legislation, and on each occasion it was handled in anything but a statesman-like way. As the law stands, *delirium tremens*, if it produce such a degree of madness as to render a person incapable of distinguishing right from wrong, relieves him from criminal responsibility for any act committed by him while under its influence; and this doctrine was extended by Mr. Justice Day to temporary derangement occasioned by drink. But to avoid contentious matter in a purely domestic measure, as successive Governments have made the deprivation of the drunkard's liberty almost impossible. If he is sent to an asylum he must be liberated on his return to sanity, though he may leave to recommence drinking, and once more become a danger to himself and the public. The authorities can commit habitual drunkards only to inebriate homes, and the Act defines the habitual drunkard as "a person who, not being amenable to any jurisdiction in lunacy, is, notwithstanding, by reason of habitual intemperate drinking of intoxicating liquor, at times dangerous to himself or herself, or incapable of managing himself or herself, and his or her affairs." Even then there are many formalities to be discharged which hinder the working of the Act. These obstacles to admission in criminal cases are not so numerous or formidable; but they so hinder admission to the licensed retreats that few but the most degraded of their class find their way in. The result is that no one is eligible for the reformatories but the very class who furnish the least promising patients. The Bill was framed on the lines of least resistance, as by excluding all those who might be benefited by acquiring habits of sobriety and industry there was the prospect of passing it without trouble. Where, however, is this habitual drunkard to go? Echo answers: where? There is no reformatory for him in existence, if we except the house in Ennis. Avoiding the difficulty of providing the necessary homes for the inebriates by placing the burden on the local authorities, and to make the expense as formidable as possible, it is required that the institution shall afford suitable accommodation for not less than one hundred inmates. The committee of the Richmond Asylum have again tackled the matter, urged on by the resident medical superintendent—Dr. Conolly Norman—and have passed a resolution directing the attention of the Lord Lieutenant to the present ineffective condition of the law. It is well known that his Excellency is keenly desirous of obtaining some solution of the lunacy question in Ireland, and consequently perhaps this time the representations of the Richmond authorities will receive more attention and succeed in effecting some practical reform.

IS APPENDICITIS INCREASING IN FREQUENCY ?

THE extraordinary prevalence of appendicitis at the present time is a favourite topic of conversation among the public generally. One is constantly appealed to to say whether it is a new disease, and, if not, what explanation can be given of its apparent prevalence as compared with days within the memory of young adults, when its occurrence was all but unknown, and figured little, if at all, in hospital records. Nothing, of course, is easier than to adopt the explanation lightly given and as lightly accepted with regard to the greatly increased mortality from cancer, *viz.*, that it is only a question of nomenclature, the selfsame symptoms having previously been described under other terms. Unfortunately, neither individual experience nor hospital records afford much support to this view. Those of our readers who are able to recall the state of affairs twenty years ago will in great measure share the surprise felt by the public at the remarkable frequency of symptoms which, in their own experience, were then but exceptionally met with, and when encountered were almost invariably benign in character. This aspect of the question is very lucidly and carefully dealt with by Dr. Y. A. MacDougall in an article published in the current number of the *Lancet*. It was not until 1887 that he first met with lethal cases of appendicitis, and since that time he has met with them in ever-increasing numbers. The most curious feature of the inquiry is that the records of several large general hospitals fail to show more than an infinitesimal proportion of cases which, by any stretch of the imagination, could be accorded the posthumous title of appendicitis. Since the records of post-mortem examinations are available there can be no question of any modification of nomenclature, and one is driven to seek elsewhere for an explanation. Even when a knowledge of the pathology of this form of perityphlitic inflammation first became generally known the cases were comparatively few in number, and the disease was considered to be one for medical, rather than surgical, treatment. The tendency to recurrence, which is now recognised to be such a marked feature of the disease, does not appear to have attracted the attention of the physicians of twenty years ago; in fact, in the light of our present knowledge, one is certainly tempted to believe that a new symptom-complex has made its appearance in the medical firmament. We must remember, however, that the ordinary attack of appendicitis is of comparatively trifling severity, and unless its grave possibilities are understood, is extremely likely to pass well-nigh unperceived. A little tenderness in the region of the right iliac fossa, a slight rise of temperature and some abdominal discomfort, associated, perhaps, with constipation, may be all that the patient complains of, and it may be conceded that even at the present day thousands of such cases are dealt with on ordinary medical lines without a thought of their

possible dependence on catarrh or inflammation of the vermiform appendix. In times gone by, the vast majority of such attacks were recovered from in the course of a few days without attracting any particular attention. They would doubtless do the same now, were it not that in order to save the lives of the minority early operation is resorted to irrespective of the gravity of the particular attack. Then, again, the undiagnosed cases of perityphlitis which, in times past, ran on to suppuration and culminated in general peritonitis or pelvic abscess did not come into hospital until a stage had been reached at which it must have become difficult to distinguish the starting point of the mischief, especially as experience had not yet taught pathologists to scrutinise with special care that intrinsically insignificant organ, the appendix. It is highly improbable on the face of it that the appendix should suddenly have developed undreamed-of aptitudes for mischief, and although the statistics of the past fail to afford any confirmation of the view we prefer to think that this was due to a failure of perception due to the lack of accurate pathological knowledge.

Notes on Current Topics.

The Partition of the Victoria University.

WE have on several occasions referred to the threatened partition of the Victoria University, and now it would seem as though the disintegration of the great Federal University of the North was inevitable. The decision of the Committee of the Privy Council appointed to deal with the matter has just been made known. It is recommended that Manchester and Liverpool be allowed separate universities, but very wisely certain restrictions are suggested, the most important being that the Yorkshire College at Leeds should be granted an opportunity of submitting a draft charter incorporating a university in Yorkshire before draft charters for Liverpool and Manchester are agreed upon. The Committee evidently recognise the danger imminent in the rivalry of three weak universities, and recommend the consideration of points upon which joint action is desirable without unduly restricting the liberty or circumscribing the responsibilities which ought to attach to independent universities. The charters are to contain provisions for the appointment of external and independent examiners, and the Crown is to reserve the right of inspection. We, with most others interested in the highest interests of university education in this country, deplore the unnecessary multiplication of small and inadequately staffed universities; but since local ambition and jealousy have insisted on the creation of three university centres all within ready reach of each other, we are glad to see that the statesman-like report of the Committee of the Privy Council indicate the urgent need of securing at least a minimum of efficiency. It would be a great calamity not only to the North of England but to

the country generally if disintegration in this case were to be accompanied by deterioration. The further steps in the disruption of the Victoria University may well be watched with anxiety by all concerned in the maintenance of a high standard of university life.

The Oyster Scare.

THE belated death of another distinguished man as the result of the fatal civic banquet held some months ago in the South of England serves to keep the memory of that tragedy alive in the mind of the public. There is no more curious instance of the mysterious laws that sway the habits of mankind than in the matter of food. The Frenchman eats frogs, snails and horseflesh, articles of diet which his neighbour of Great Britain loathes with unspeakable horror, although for all that the things mentioned are all wholesome, nutritious and clean. Yet the insular fashion which damns snails simply revels in another mollusc eaten raw, to wit, oysters. Now that sad experience has forced upon the British public the fact that typhoid fever and other diseases are often due to eating infected oysters they have stopped indulging in that dainty with the utmost unanimity and it is open to question whether their confidence will ever be restored. It seems almost hopeless to expect oyster breeders and distributors to take effectual steps in that direction, considering that they have done nothing in spite of several years of solemn warning and full information from Government reports. The pollution of oysters is absolutely preventible; who will prevent it? Will Government step in? It seems to us that in any case it will be necessary to devise some simple means of identifying oysters that have been kept under wholesome, sanitary conditions. Some time ago, if we remember aright, it was suggested by a medical man that each shell should be earmarked by a token that should guarantee the source of the oyster. Oyster merchants who want to regain their trade should make a note of that suggestion.

Influenza in Its Remoter Aspects.

DURING a long period influenza has left a lurid record in the death-rates recorded at Somerset House. For a dozen years or more this epidemic scourge has lingered in our midst and has claimed a toll of victims that, taken altogether, reaches an enormous total. When the wave of infection will finally recede from the United Kingdom cannot be foretold by the physician any more than by the ploughboy. Now and then during the present prolonged outbreak a temporary lull in the invasion has encouraged the belief that the enemy had retired from the field, a hope that has hitherto been invariably shattered within a short period by the appearance of the ominous newspaper paragraph under the familiar title, "A Recrudescence of Influenza." Apart from the actual deaths due to the disease, however, there is a serious aspect of the matter to which the attention of the medical

profession is gradually becoming awakened, namely, the indirect influence of post-influenzal conditions upon the general health of the community. It has long been known that the lessened cardiac vitality, often following an attack of the malady in question, was often of a most chronic nature, lasting for years, and predisposing to various circulatory disorders and other complications. It may be questioned whether influenza has not a marked influence in setting up arterio-sclerosis, and in that way shortening life. From the nature of the case it is difficult to obtain exact evidence upon the point. At the same time it would be well for statisticians in estimating the extent of an influenza epidemic to bear in mind the desirability, if possible, of taking into consideration the remote as well as the immediate bearing of the disease upon the mortality returns.

Lift Accidents.

THE rapid increase of fatal accidents in "lifts" suggests the necessity for more stringent legislation with regard to that modern domestic convenience. The high value of land has induced landlords to build skywards, with the natural desire of making as much money as possible out of their sites. Hence the modern town building of many storeys, a plan of construction that in turn necessitates the use of lifts to save inmates and their servants and visitors the toil of climbing up and down endless flights of stairs. The hydraulic lift is clearly the right thing in the right place, but it has nevertheless introduced a new and terrible danger into social life. What strikes one most forcibly in the account of this species of tragedy is that in a large proportion of cases the accident has been purely and absolutely preventible. Sometimes a rope has broken, or the lift has been in charge of an untrained servant, or some simple precaution has been neglected. Fortunately, the lawyers have fixed the responsibility for resulting accidents upon the lift-owners. In a recent case the landlord attempted to escape liability by pleading that the lifts were placed by him in the building for the convenience of his own tenants therein, and not for the visitor who met with the accident. That contention was happily dismissed by the judge. By the enforcement of stringent regulations as to the construction and control of passenger lifts it would be possible to reduce accidents therefrom to a minimum.

Railway Hospital Saloons.

IT has been decided to provide saloons on the Southern Pacific Railway, specially fitted for ambulance work, the cars being furnished with all the appliances and conveniences for the first care of the injured. The service will be under the control of a medical officer. Although accidents in this country are, in general, neither as frequent nor as serious as our trans-Atlantic cousins indulge in there is certainly room for some such accommodation here. The rough and ready appliances which alone are available cannot but increase

the suffering and add to the risk of the victims of accidental injuries. Each section of all important railways ought to have such a car stationed within easy reach and in telephonic communication with the local headquarters. Even on economic grounds the innovation ought to pay, to say nothing of the consideration which injured passengers have a right to expect at the hands of the companies. During the year ending June 30th, 1901, there were 282 passengers killed and 4,988 passengers injured in United States railway accidents. During the same time there was not a passenger killed by train accident in all England, Scotland, Wales, or Ireland. Including employes, trespassers and level-crossing victims, the total figures of accidents in the United States from railway accidents are for the year ending June 30th, 1901, 61,794—killed, 8,455; injured, 53,339. Of employes one out of every 400 was killed, and one out of 26 injured. Of passengers one was killed for every 2,153,469 carried, and one injured for every 121,748 carried.

Lead-Laden Water.

MUCH additional light has been thrown on the chemistry of lead poisoning by drinking water in the recently published report of Mr. W. H. Power, medical officer of the Local Government Board. A very painstaking and comprehensive survey of a large number of water supplies obtained from moorland districts reveals the fact that the organic acids contained in water from such sources possess more or less marked plumbo-solvent properties. In 35 out of 58 reservoirs examined the water possessed this property, so that when brought into contact with leaden pipes more or less mineral contamination would ensue. Fortunately such waters can readily be divested of their deleterious characteristics. The excess of acid may be neutralised by admixture with a sufficient volume of neutral or alkaline water or by filtration through sand or limestone. The practical outcome of the inquiry is the advice that the various sources from which a water supply is obtained should be methodically tested at different seasons of the year in respect to their plumbo-solvent properties, and the necessity is inculcated of a careful survey of the physical characters of the gathering grounds. The fact that comparatively few persons drink water in sufficient quantities to contract lead poisoning does not afford a trustworthy test of the potential mischief wrought by lead-bearing water, since this enters into the composition of all beverages except wine, cider, and other fruit juices.

Tramps and Small-Pox.

THE present epidemic of small-pox in the provinces furnishes a useful object-lesson in regard to the important part played by nomads, *alias* tramps, in the dissemination of the disease. At present the Poor-law authorities are powerless to enforce vaccination, and unless the casual inmate of a workhouse has actually contracted the disease, he can defy all the regulations made for his benefit

and in the interests of the community. This is a point which ought not to be lost sight of in any future legislation and it is hardly to be anticipated that any opposition would be offered to a compulsory clause. From all parts of the country lamentations are heard over the difficulty of preventing the spread of small-pox so long as these irresponsible folk are allowed to wander far and wide free from any sort of control. Incidentally the question suggests itself whether some more efficient check could not be placed on the perambulations of these, the unattached members of the community. They are for the most part of a low order of intellect and are imbued with a profound distaste for work of any kind, so that a little wholesome discipline would assuredly be productive of good both to them and to the community.

A Lorenz Hospital for New York.

ONE of the results of Professor Lorenz's visit to America has been that steps have been taken to establish in New York an institution for the cure of deformities after the Lorenz method. Already application has been made for papers of incorporation for a hospital which will bear the name of the Lorenz Orthopædic Charity Hospital. As was only to be expected many American plutocrats have interested themselves in the matter, and the success of the undertaking seems to be assured. Even before the visit of Dr. Lorenz to New York, the foundation of such a hospital was discussed. Dr. Sylvester, at one time an assistant Professor at the Post-Graduate Hospital, was approached on the matter, and, in conjunction with Mr. W. S. Brewer, took the first steps. As soon as the incorporation of the institution is accomplished, definite plans for its management will be laid before the supporters, and temporary quarters will be obtained and the work started. In a wealthy city like New York there ought to be no difficulty in obtaining the required sum for what at the moment is a popular scheme. Whether the ultimate results of the undertaking will prove as successful as is hoped is another matter, but it is clearly advisable that every step should be taken to test the value of Professor Lorenz's methods.

A Legal Method of Preventing the Spread of Syphilis.

AN important judgment has recently been delivered in Paris by the Tribunal of the Seine, by which the transmission of syphilis by persons knowing themselves to be affected, even though they do not willingly transmit the disease, becomes a penal offence, for which an indemnity can be obtained by the recipient. In the case before the court, a man suffering from syphilis had sexual intercourse with, and infected, a girl aged 16, who had previously been perfectly healthy. The Court granted her substantial damages to the extent of 12,000 francs. This judgment will have far-reaching effects. It constitutes in our opinion a great advance not alone in justice but in preventive medicine. No Contagious Diseases Act could ever be as effective as the knowledge that the

transmission of syphilis can be punished by a heavy monetary penalty. If proper precautions can be devised to avoid black-mailing, and this is a danger which must be taken into consideration, we should very much like to see a similar judgment delivered in these countries. The neglect of the legislature to provide a special mechanism to prevent the spread of infection could be to some extent disregarded, if the transmission of infection was an offence under the common law. The national carelessness to the sufferings which result from syphilitic infection is a standing disgrace to the civilisation of the nation, and should be a constant reproach to those misguided enthusiasts who are responsible for it.

Insurance Against Appendicitis.

WE learn from a contemporary that insurance firms, like everyone else, must move with the times, and that the latest security which is offered by the world-known "Lloyd's" is an insurance against appendicitis. The prevalence of appendicitis, or perhaps its fashionable character, has suggested to one of the most prominent firms in Lloyd's, that perhaps a cautious public might like to insure against its risks, and so for a premium of five shillings the assured, who suffers from appendicitis, will receive a sum which will go a long way towards discharging his bill for medical attendance. In return for this premium, if the assured has to undergo an operation for appendicitis he will have his direct expenses paid up to £200, or, in the event of his death under, or from, the operation, his representatives will receive a like sum. It is stated that a large number of people have availed themselves of the offer, and are now protected from the monetary losses which an attack of appendicitis might involve. The premium charged, two and a half per cent., is identical with that asked a year ago for insuring against small-pox, and should prove a source of profit to the enterprising guarantors. Our contemporary omits to mention whether any preliminary precautions are taken to ascertain whether the insurer has an—outwardly, at least—healthy appendix, but we presume that such is the case, and that he must be furnished with due medical credentials to that effect.

Objectionable Advertisements.

OUR attention has been drawn by a correspondent to an advertisement, which appears among the news items, in the columns of the *Armagh Guardian*, and which is of a nature that should prevent it from finding a place in the columns of any respectable paper. It is addressed to "married couples who would live happily and free from the cares of a large family," and emanates from an establishment which calls itself the "Northern Surgical and Rubber Appliance Company." The term "Guardian," as applied to a newspaper in former days, meant that the paper concerned itself with the interests of the people—whether material or moral. It seems, however, that such a term is sadly abused in the case of the journal referred to. The appearance of such an

advertisement is directly detrimental to every interest of the people. A diminishing population should be a matter of concern to members of the community, yet a self-styled "Guardian" lays before its readers a method of bringing about a further diminution. From a moral point of view, the publication of such filth is also objectionable, and we wish to draw the attention of the authorities of whatever religious community the *Armagh Guardian* is the representative. Our correspondent asks us, "Can nothing be done to prevent the publication of such filth?" In some instances the police have of late been roused to prosecute the offending parties, and an effort should be made to compel them to do so in this case. Another method of stopping the appearance of such advertisements is to cease subscribing to papers which insert them.

The Poisons of Liqueurs.

THE influence of liqueur drinking upon the system has an everyday importance, yet it is curious how little is really known upon the subject. The peculiar evils wrought by various alcoholic drinks, as, for instance, beer, gin, sherry or brandy, are fairly well known to all and sundry. When we turn to liqueurs, however, the common verdict is vague, nebulous, and contradictory. Beyond a general notion that it is unwise to drink more than a single glass of liqueur or to mix that seductive form of fillip with other drinks, the man in the street is opinionless upon the matter. The smallness of the liqueur glass is to him a standing warning of the potent effects of the fluid for which it has been designed, and beyond that all is *terra incognita*. The French Academy of Medicine have now announced to the world the breadth, length and depth of that potency. Many of the essential oils used in the manufacture of liqueurs are venoms of the deepest dye, as, for instance, that quickest of all poisons, prussic acid. The essential oils, in themselves highly deleterious, are chiefly used for the purpose of disguising the taste of cheap alcohol, so raw and fiery that it could not be swallowed in its natural state. Some of the Academy speakers suggested that liqueurs containing methylated spirit should be absolutely forbidden, as well as those containing fruit kernels charged with prussic acid, and those made with poisonous essential oils, such as essence of carraway and of absinthe. It is well known, of course, that both essential oils and alcohol act as powerful poisons of nerves, to say nothing of other organs, if given in sufficiently large doses and over a sufficiently long period of time. Has the Paris Academy of Medicine given the death-blow to liqueur drinking? If so, the world at large will be at no great loss thereby. There is no better cordial in the world than a homely, well-matured liqueur, in the making of which good alcohol has been used, together with flavourings that have kept their proper place and not degenerated into clumsy and dangerous disguises of poisonous spirit. On the whole the drinking of liqueurs as ordinarily met with in society must be condemned as incurring a gratuitous risk.

Mr. Troutbeck versus the Profession.

A CERTAIN gift of pertinacity must be conceded to Mr. Troutbeck, the Coroner for Westminster. His predilection for the services of Dr. Freyberger in the making of post-mortem examinations remains unchanged, and he is never at a loss for a justification of his preference, which is based on an invidious comparison with the inadequate, or positively misleading, evidence which "would be given" by those in medical charge of the case under investigation. In one case Dr. Freyberger discovered that there was rupture of the heart, "which, with the consequent hæmorrhage, was sufficient to cause death." Although pathologically interesting, the information hardly assisted the jury in arriving at the conclusion that the child's death was due to natural causes, and no doubt the practitioner in attendance would have discovered the lesion just as Dr. Freyberger did. In another case the practitioner in attendance on the deceased ventured to ask why he had not been entrusted with the post-mortem examination, but Mr. Troutbeck promptly declined to allow his discretion to be called into question in spite of the fact that poor Dr. Freyberger's hands were in such a state that he did not conceive it to be safe for him to take off his coat or to take any manual part in the examination. With Dr. Freyberger a glance is sufficient and palpation of diseased organs would be of the nature of supererogation. The odd feature of the controversy is that there is no divergence of opinion as to the propriety of employing a specially qualified pathologist in special cases, but the war rages around the exercise of the coroner's discretion, which, as a matter of fact, is exercised in a very arbitrary and irritating fashion.

Anæsthesia and Death from Fright.

THAT death may, under certain circumstances, result from severe fright can hardly be questioned though such occurrences must in any event be extremely rare. That death can occur from this cause in an ordinary healthy individual is inconceivable. Fright, however, is incriminated as one of the possible factors in the causation of death under anæsthetics, especially in what one may term the pre-anæsthetic stage; that is to say, before consciousness has been abolished. No doubt fright may act prejudicially in the subject of chronic myocarditis or other form of cardiac weakness, and possibly also in persons who have reached an extreme state of organic debility, but there is no convincing evidence to justify the belief that mere dread of the anæsthetic can *per se* exert a material influence in the production of the fatal result. We are told that in most instances death from chloroform is due to vasomotor paralysis, and that death from fright occur in the same way, and we are invited to concede a similar etiology, in both cases. We should like to know, however, on what pathological data the assertion as to the mechanism of death from fright is founded, since it obviously cannot repose on any very large number of observations. The common-sense view would be that fright is but one factor in deter-

mining death, and we are profoundly sceptical with regard to deaths alleged to have occurred after the administration of "a few drops of chloroform."

The Fear of Draughts.

THE love of fresh air is certainly not one of the most salient characteristics of civilised man, on the contrary, every device, short of determining immediate asphyxia, is resorted to to prevent the free access of fresh air to our dwellings. The dread of the draught amounts in a large proportion of men and women to a monomania, and the slightest suspicion thereof suffices to render them wild with terror. One result of the propagation of the gospel of fresh air to which we may confidently look forward is a more general recognition of the fact that the average draught can be borne with impunity by those who have accustomed themselves to breathing fresh air day and night. There are circumstances—such, for instance, as a very pronounced difference between the outside and inside temperatures—which may render a draught not only uncomfortable but positively injurious, but this must be guarded against, and does not justify the fear which a mere current of fresh air usually inspires. Theoretically, perfect ventilation provides fresh air without perceptible draught, but such ideal conditions are rarely attainable, and we must put up with a moderate draught or forego fresh air altogether. If the persons who know by experience that a draught means a cold would only try the experiment, commencing in favourable weather, of throwing open wide their windows to the air by night as well as by day they would soon gain an immunity to cold which would surprise and delight them.

Legislative Omissions.

THE King's Speech in opening Parliament is, from a medical point of view, more remarkable for its omissions than for its promises. Foremost among the things that were left unsaid was the impatiently-expected announcement of the intentions of the Government with regard to vaccination legislation. Steps will doubtless be taken to elicit information on this point from the President of the Local Government Board, as the matter is hardly one which admits of delay. In view of the evidence which has recently been accumulating in regard to the pollution of shell-fish by sewage, it was thought that an endeavour would be made to check the spread of disease by such means, but on this point also the Royal Speech was silent. Even the urgent and oppressed subject of the reform of death registration did not secure a mention, although a Government measure dealing with the notorious shortcomings of the present system would probably pass as a non-contentious piece of legislation.

WE regret to learn the death of Mr. W. J. C. Miller, who for upwards of twenty years was registrar of the General Medical Council.

A Crucial Test of Malingering.

IN an employer's liability case which was being tried a few days since at the Llanelly County Court, the judge had to decide between the conflicting evidence of the medical referees. It was alleged on the one hand that the injured man was suffering from paralysis and loss of sensation in one arm, while on the other it was asserted that the man had recovered. It was stated that the man had not flinched when a red-hot iron was applied to the injured arm, and a repetition of the experiment was suggested, a proposal to which the judge took instant exception. An investigation of the electrical reactions by the medical witnesses in common would probably have brought them to see the case in the same light, but in any event the matter was one to be decided by the medical men without reference to the judge, who could hardly be expected to appreciate the significance of clinical tests.

A Bacterial Equation.

THIRTY years ago there was not a printed page upon bacteriology in the British Museum Library, states an essayist in the current issue of *The Academy and Literature*, while now there are no less than four hundred volumes. The manner of the combat, the inter-action of hostile forms of life, is now being revealed so clearly that it is proposed to express the matter by an equation which runs thus.—

$$D = \frac{MVN}{R}$$

This equation is claimed to represent some approximation to theoretical exactness: "D, the disease, equals M the micro-organism, multiplied by V, its virulence, multiplied by N, its number; the product being divided by R, the resistance of the individual attacked." All this to the mathematical enthusiast may be helpful and reassuring, but the rational therapist never claims for medicine a place among the exact sciences, and discourages the application of rigid methods which, instead of directing, in only too many instances do little more than hinder and hamper true progress. It is well that clinical medicine should shake itself loose from the too dogmatic grasp of the short-sighted theoretical bacteriologist.

The Leucocytosis of Appendicitis.

MUCH has recently been written concerning the occurrence of leucocytosis in appendicitis and cases of abdominal suppuration. Some insist that in every suspected case a blood count should be made, while others believe such a method of investigation instead of being useful may actually mislead. Dr. G. Lovell Gulland discusses the situation in the February number of *The Scottish Medical and Surgical Journal*, and arrives at the following helpful conclusions: On making a blood examination in appendicitis, if a leucocytosis of 20,000 or more is found, the condition is serious and demands operation, unless the count rapidly falls with improvement of symptoms. If the count is below 20,000 a differential count of 500 cells should be made. If

80 per cent. or more are polymorphs then operation should be undertaken; but if the proportion is between 70 and 80, surgical interference may be delayed; and if below 70, will probably not be necessary. If, however, the iodine reaction is marked, operation is probably always indicated, except perhaps in the hopelessly septic cases with a low leucocyte count. At present there are no data for correlating polymorph percentage with iodine reaction.

The Details of Military Efficiency.

UNTIL very recently the minor requirements of the soldier on the march have been ignored, but a new era has now been entered upon. Henceforth the soldier will not be left to endure as best he may the pangs of toothache, provision having been made for first-aid dental treatment. On the same lines arrangements have been made for the services of regimental chiropodists, whose ministrations will assuredly conduce as much to rapid and continuous marching as all the emergency rations in the world. We have but to imagine the plight of a combatant who happens to be suffering from toothache and a suppurating corn to understand that success in the field depends upon a multitude of minor details which cannot safely be ignored.

THE Second International Congress of the Medical Press will take place at Madrid on Monday, April 20th, under the personal presidency of the King of Spain. Those who are desirous of attending are requested to communicate with Dr. Larra y Cerezo, 17, Léganitos, Madrid, who should receive notice of any papers to be read thereat. The general secretary of the Association is Dr. R. Blondel, 8, Rue Castellane, Paris.

M. LESAGE has introduced a method by which measurement of electric resistance is employed as a method of analysing the effect of fermentative and certain pathological processes.

MR. HARRY BOLTON SEWELL has been appointed Coroner for the Greenwich division of Kent. Mr. Sewell is at present deputy-coroner for the South Eastern district of London.

SIR HENRY BURDETT, K.C.B., will open a discussion on "Hospital Sites and Population in London" at the Caxton Hall, Westminster, on March 3rd.

DR. PATRICK MANSON is to open a discussion at the next meeting of the Epidemiological Society to-day (Wednesday) on "The Panama Canal and the Introduction of Yellow Fever into Asia."

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

EDINBURGH.

[FROM OUR SPECIAL CORRESPONDENT.]

ENDOWMENT OF POSTGRADUATE STUDY AND RESEARCH BY THE CARNEGIE TRUSTEES.—The regulations under which research is to be endowed have just been issued by the trustees, and from these it appears that

three classes of benefaction are contemplated—scholarships, fellowships, and grants. The precise number of each annually available will depend on the relative number and character of the applications received. The scholarships are intended to afford promising graduates an opportunity of training and proving their powers in higher study and research, and may in this way qualify scholars for the Fellowship, for which evidence of research already performed is expected. A scholar or Fellow shall not be allowed to engage in other work that would interfere with the progress of his research, and where other work is proposed to be undertaken, its nature, and the time it will involve, must be definitely stated in the application. A scholarship is of an annual value of £100, and shall not be held along with any other scholarship or position of emolument, unless with the sanction of the executive. In the event, however, of a candidate holding another such scholarship, &c., the committee may, instead of granting a Carnegie scholarship, supplement the emolument received by the applicant so as to bring the income up to at least £100. The whole of the scholar's time shall ordinarily be devoted to the work, and the tenure is for one year, renewable for a second period. Fellowships are granted on much the same terms, but only to those who have already shown signs of ability in research; they are of an annual value of £150, tenable for two years, and renewable for a third year. These scholarships and Fellowships are given in medicine and science, and in history, economics, and modern languages. While any attempt to endow scientific work must be hailed with gratitude, one cannot but admit to a feeling of disappointment on reading the committee's proposals. Those who know best what original research means will be the first to doubt whether looking at the matter from a purely commercial standpoint (the Carnegie trustees will get "value for their money.") The obvious intention of the trustees is that the scholarships shall afford a means of training for the Fellowships, since candidates for the latter are expected to show evidence that they have already done research, while from the would-be scholars this is not expected. Now it will readily be granted by those who have done any original work that at least a year must elapse, in most cases, before a worker passes the tyro stage, a newly qualified graduate has had his time so fully occupied with examination and purely professional studies that he has no idea of how to set about research; how many, for instance, have even the vaguest notion of how to get up the literature of a subject before investigating it? To expect original observations of any value after one or even two years' research is simply putting a premium on the work of novices, with which present day scientific literature is too familiar already. At the same time, though the short term scholarships cannot in the nature of things be productive of great results, they will at least serve the purpose of testing the capacity of those who propose devoting themselves to research, and if the trustees had seen their way to founding Fellowships of real value, to be held only by the selected few, much more scientific advancement might have been expected than from the present scheme. As it is, it is difficult to see who can hold these Fellowships, except those with private means. It is therefore to be feared that the growth of knowledge will not be promoted by the endowment to an extent at all commensurate with the money spent, and it cannot be supposed that three workers (who, under the present scheme, *must* do something else for a livelihood) will turn out work at all comparable to that of one man of proved capacity who could give all his time to the work, because he is relieved of the necessity of earning his bread otherwise.

FINANCIAL POSITION OF ABERDEEN UNIVERSITY.—The general fund of the University shows a surplus of revenue over expenditure, for the year ending September, 1902, of about £625. The principal cause of the surplus is the payment of students' fees by the Carnegie Trust, rather than the slight increase of students, as the students were thereby enabled to take a larger number of classes than formerly, the average sum per head paid being £10., as against £9 in the previous year

A further increase from this cause is anticipated. In certain directions the expenditure is higher than in the preceding year, but in future the drain on the general fund for the salaries of certain lecturers will be checked by the new arrangement which the Carnegie Trust has enabled the Court to make with the lecturers in modern languages and history. The debt of £20,000 for buildings, which existed in 1900, has been reduced to close on £5,000. The convener of the Finance Committee states that the salaries of the Theological professors are lower than in previous years owing to declining revenue from endowments. Though bequests to the amount of £21,000 have been received this year, at least £340,000 is still required for endowment and equipment.

GLASGOW.

[FROM OUR OWN CORRESPONDENT]

HOSPITAL ACCOMMODATION IN GLASGOW.

At present, and for some time, the hospital accommodation in Glasgow has been found to be quite inadequate to meet the many cases which are daily presenting themselves at the Royal, Western, and Victoria Infirmaries. Numerous cases have to wait a considerable time before being admitted, and in serious cases this is very unfortunate, and may even be followed by disastrous consequences. The managers of the Victoria Infirmary have just acquired, or at least have offered for a considerable portion of ground belonging to the Corporation and adjacent thereto, with a view to making an addition thereto. Then the Western Infirmary managers are making an appeal for funds with which to build a new wing to the hospital. Already a generous response has been made. Lord Overtoun subscribes £1,000, Messrs. Arthur and Co., £1,000; and five other firms subscribe £500 each; while others give smaller sums. Altogether the result so far has been very encouraging. What is to be said with regard to the reconstruction of the Royal Infirmary, the inception of which was in 1897? All that can be said is, that notwithstanding the clamant need for more accommodation, it will be a long time before the full scheme will be completed. Plans were prepared a considerable time ago, to carry out which a sum of, at least, £250,000 is required. Of that sum somewhere about £90,000 has been subscribed. Some of the subscribers have complained of the apparently undue delay in getting a start made, and surely not without good reason.

SOUTHERN MEDICAL SOCIETY, GLASGOW

A LARGE number of the members of the above Society availed themselves of the invitation of Dr. W. F. Somerville to visit his home or private hospital in South Park Terrace, Hillhead, on the evening of Thursday, the 19th inst., where electrical treatment is carried out in a very thorough manner in quite a variety of diseases. Among those present there were Professors McCall Anderson and Ralph Stockman, Drs. Renton, Sloan, Robertson, Young, Thomson, Neil, Brown, Hamilton, Orr, Wauchope, Rowan, McKendrick, Watson, Richmond, etc. Dr. Somerville read a paper entitled "Notes on a few cases treated with benefit by means of high frequency currents." A patient was shown who suffered very acutely from sciatica for three months, who was cured by means of the electrical treatment. A woman who suffered from lupus erythematosus was next shown. The lupus patches had almost entirely disappeared. Another patient was present who was considerably relieved of troublesome varicose veins of the legs with eczema. In cases of hæmorrhoids improvement often follows the adoption of this line of treatment. In the discussion which followed Prof. McCall Anderson and Drs. Renton and Sloan took part, all bearing testimony to the efficacy of electrical treatment in certain cases. Dr. Somerville explained very fully the apparatus used, and demonstrated the use of the same on the person of the president of the Society and others. While electricity is a very potent therapeutic agent, it was shown to be painless as used

by Dr. Somerville, and can be successfully applied in a varied class of cases. The demonstration was a very interesting and instructive one, and at its close Dr. McGillvray, the President, proposed a vote of thanks to Dr. Somerville, which was responded to most heartily by all present.

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

THE DISRUPTION OF VICTORIA UNIVERSITY.

THE decision of the Privy Council in favour of granting charters to separate universities in Manchester and Liverpool has been received here with great satisfaction. The inauguration of a local University with an independent existence will, it is thought, be a great stimulus to academic life. One of the earliest results will doubtless be that money will be forthcoming from various sources which was not available either for a college or for a composite University. This result may also be anticipated in Liverpool and in Yorkshire, where Leeds and Sheffield will soon be hard at work on a University of their own.

So far as the Faculty of Medicine here is concerned nothing is needed but a good hospital near the College buildings. It is earnestly hoped that the new board of management of the infirmary will make some arrangement by which their new building and the new Southern Hospital may both be erected on or near the Stanley Grove site. The portion of that site already secured by the authorities of the Southern Hospital forms so important a part of the whole that without some kind of amalgamation scheme the two hospitals could not both be built there. The other alternative is for the authorities of the Southern Hospital to give up their portion of the site in exchange for another equally good one in the immediate vicinity.

About the middle of last century a hospital was founded in North Manchester with the curious name of the "Clinical Hospital" for Women and Children. This name has long been held up to ridicule by medical men, but it is only in this year of grace that the gradual spread of education has advanced sufficiently to lead the committee to change it. It will now be called the "Northern Hospital," and, it is to be hoped, will be more widely known than heretofore. A large amount of most useful work in gynaecology and diseases of children has been done by this institution, but the members of the committee and of the medical staff have been very quiet and retiring. Old subscribers have died, and new ones have not been sought with sufficient energy. The hospital, however, is not yet deeply enough in debt to attract much sympathy, and its authorities will doubtless have to double their number of beds and erect spacious new buildings in order to secure the help of the charitable public.

Very little notice is being taken of the so-called epidemic of small-pox. Some of the public vaccinators have done a great deal of work, to the disgust of their colleagues in private practice. The rush, however, seems to be dying away, and only a stray red band is to be seen in the streets of the city.

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

ULSTER MEDICAL SOCIETY.

THE fifth meeting of the Session was held in the Medical Institute, Belfast, on Thursday afternoon, February 10th, Dr. Agnew, of Lurgan (vice-president), in the chair. Dr. McKisack showed a case of spastic paraplegia which seemed to be due to primary lateral sclerosis. Dr. Darling read a paper on an interesting case of "Effusion into the Pericardium," which we hope to publish in our next issue. Dr. McKisack related the latter part of the history of the case, and Drs. McCaw, Dempsey, and Robert Boyd discussed it. Dr. McCaw read notes of a case of paroxysmal hæmoglobinuria in a child, and showed the patient. Dr. Houston showed the head of *Tænia solium* and the body of *T. medio canellata*, the latter 21 feet 6 inches long. Dr.

R. L. Bell, of Hollywood, was elected a Fellow of the Society.

BELFAST MATERNITY HOSPITAL.—The 109th annual meeting of this old-established charity was held on February 17th. The medical report stated that during the year 1902 there were 312 patients in hospital, 271 children born, and only one patient died.

MEDICAL EXPENDITURE IN THE BELFAST UNION INFIRMARY.—This subject, several times referred to in these columns, was up again at a meeting of the guardians on February 17th, when a letter was read from the Local Government Board. "The Board observe with satisfaction," it stated, "that the medical officers fully endorse many of the recommendations contained in Dr. Smyth's report on the late inquiry. The Board learn from Dr. Smyth that during a recent visit to Belfast he was favourably impressed with the spirit shown by the medical staff, and also by the medical committee of the Board of Guardians. He states that he was satisfied that both the medical officers and the committee were earnestly endeavouring in a practical and successful way to carry out the wishes of the Local Government Board."

Correspondence.

THE PROFITS ON THE SALE OF SURGICAL INSTRUMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The absurd prices charged by many, probably most, surgical instrument makers for appliances and instruments really suggest the desirability of a co-operative union of practitioners in order to enable them to satisfy their requirements on reasonable terms.

During the past week I had occasion to negotiate the purchase of various instruments. In the West-end the prices asked varied from 15s. to 30s. for instruments which I subsequently obtained from a City house at a cost from 50 to 70 per cent. cheaper, although, as far as my inspection permitted me to judge, the quality was exactly the same.

To ask 15s. for an article which is sold presumably at a fair profit by another firm for 4s. 6d. savours of extortion, and I daresay many of your readers could parallel this experience.

I am, Sir, yours truly,
AN UNWILLING VICTIM.

STUDENTS AND THE POOR-LAW MEDICAL SERVICE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I address you on a matter of grave importance to medical students, especially to those who intend to remain in Ireland and seek positions under the Local Government Board after the completion of their medical curriculum. The subject to which I am about to refer ought, at least, to receive some consideration from the students of our various medical schools. The Poor-law service forms one of the most important departments of the medical profession in Ireland. Why not organise school branches of either the Poor-law Officers' Protection Association or the Irish Medical Association.

These associations, although yet in their infancy, have wrought incalculable benefit to the medical practitioners in whose districts they have been established. The present salaries paid to our dispensary medical officers range from £35 to about £100 per annum; and for this miserable wage they have to be at work probably night and day attending to the poor of a whole countryside.

Dr. Laffan, of Cashel, has calculated that each dispensary officer attends on an average one thousand cases a year, and for this he receives the munificent pay of from fourpence to sixpence for each town case, and an average of about twenty-pence for each country case. His physical labours are of the severest, his anxiety is the keenest, and his outlook the least ambitious of any official in the public service. Every other

day he has some annoyance or other to experience from a troublesome guardian or an ungrateful patient.

When we come to look at the ultimate prospect which remains for him, when sickness or old age overtakes him, he can hardly be congratulated on its brightness. His superannuation entirely depends on the free motion of his former masters, and he is even obliged to resign before he can put their good nature and sense of justice to the test.

However, these associations intend to change all this. They intend to abolish the ridiculously low salaries at present paid to our medical Poor-law officers, and at the same time to seek for liberal superannuation allowances after reasonably long services.

If the Dublin medical schools form branches of either of the above admirable associations, I imagine that their example will be followed by our other Irish schools, so that in the course of a few years, when all the young practitioners are members of an association, when they go forth on the world in an organised form, they can seek and demand justice at the hands of their employers.

I am, Sir, yours truly,

THOMAS J. MADDEN.

Student, Cath. University Medical School.

[Our correspondent's suggestion is an admirable one, and is well worthy of the attention of the medical students of Dublin Branches such as he suggests should be connected with the Irish Medical Association. They would serve the purpose of instructing students in the present condition of affairs, and would be the means of starting them in life with a knowledge of Irish medical matters—a knowledge which it would take them many laborious years to acquire for themselves. Up to the present the system has been alone kept going by the supply of young men who rushed eagerly into it, ignorant of the consequences of their action. Now a fuller knowledge of the situation prevents candidates from applying, and as a means of increasing this knowledge student organisations would be of great value—ED.]

THE TREATMENT OF IDIOPATHIC EPILEPSY BY BROMIDES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read the above paragraph in the MEDICAL PRESS AND CIRCULAR with much interest and instruction. I am sorry I cannot advance much in the control of this dreadful disease, but there is not the least doubt that bromides act much better when given under strict dietetic condition. I believe by practice the best diet is fresh vegetables, ripe fruit, fish, white meat. Red meat, highly seasoned dishes and pickles should be avoided. Regular hours and exercise also aid to prevent the attacks. There is another point I think is very important in the treatment, viz., to keep the bowels regular and the alimentary canal aseptic. Bromide of ammonium has always proved the best preparation of bromine in my hands (if it is fresh and pure) and should the physician be able to calculate the date of a fit, belladonna should be added three days before the anticipated date. I may add in conclusion, I am afraid too many physicians and patients look upon the disease as almost incurable, and do not persevere with the treatment in such a dogged manner as they should do in so obstinate a disease.

I am, Sir, yours truly,

THOMAS DUTTON, M.D., M.R.C.P.Ed.

7 Manchester Square, W., Feb. 18th, 1903.

THE VENTILATION OF TUBE RAILWAYS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am among those who have been latterly compelled to give up the use of the "twopenny tube" in consequence of the foulness of its atmosphere. The ill effects of a daily journey occupying not more than ten minutes have been too palpable to be ignored. The depressing effects can be perceived from the

moment one arrives on the platform—the peculiar odour, the high temperature, and the vitiated air combine to produce a feeling of depression, often continued throughout the day by a kind of malaise never experienced save after exposure to this cause. It would be interesting to learn what has been the effect upon the health of the conductors who spend their days on the platforms of the cars. The men as a rule look pallid, and their languor seems testified to by the perfunctory way in which they perform their duty of crying out the names of the stations. At first this used to be done with vigour; now, if done at all, the tones are mostly inaudible. The tube is of such great convenience to members of our profession that—not to speak of the public health, which is to some extent menaced by the evil—you will do a great service if you having begun to-day, will continue to use your influence in urging the directors to hasten their measures of improvement.

I am, Sir, yours truly,

F.R.C.S.Eng.

Cavendish Square, Feb. 18th, 1903.

Literature.

MUIR AND RITCHIE'S MANUAL OF BACTERIOLOGY. (a)

THIS book, of which the third edition is before us, is one of the several good student's manuals of bacteriology in common use at the present time. This edition has been written up to date, and among other additions it contains a chapter on the bacteriology of soil, air, and water. The book deals only with the bacteria pathogenic for human beings.

So far as its size permits it gives an excellent account of the different organisms and their effects. The usual cultural and microscopic methods are described and the directions are in most cases sufficiently explicit to enable a student to carry them out. In some cases, however, the description is not quite complete. Thus on page 345, in the description of Neisser's method for staining diphtheria bacilli, the fact that the preparation should be washed with water after the Vesuvin stain is not mentioned. Nor is the fact that the Loeffler's serum should be made from ox blood.

The description of Leishman's method of Romanovsky staining for malarial parasites (we allude to method No. 2) is also incomplete.

In the description of the process of embedding in paraffin, the times given for the tissues to remain in the different media are unnecessarily long. Indeed, twenty-four hours in absolute alcohol is, in case of materials (such as the skin) containing much fibrous tissue, absolutely injurious.

In the description of the method of recognising the diphtheria bacilli by culture it is stated that "Circular colonies of diphtheria bacilli are visible in twenty-four hours." It is well known that diphtheria bacilli may be recognised in culture at a much earlier time than this, often in nine or ten hours, and indeed by means of impression preparations from plates of Loeffler's serum in six hours. This latter important method is not mentioned at all.

On page 83, in a footnote, it is stated that cover glasses of greater thickness than .14 m.m. are not suitable for use with a 1-12 inch lens. This is surely an error. Leitz expressly recommends that a cover glass of .17 m.m. thickness should be used with his 1-12 inch oil immersion, and Zeiss lenses are corrected for a medium thickness of cover glass between .15 m.m. and .2 m.m. The lenses of both these makers are much used in these countries.

The chapter on Immunity is as good as its necessary shortness and the complex nature of its subject permits. There are appendices on small-pox and vaccinia, malarial parasites, hydrophobia, and amœbic dysentery.

(a). "Manual of Bacteriology." By Robert Muir, M.A., M.D., F.R.C.P.Ed., Professor of Pathology, University of Glasgow, and James Ritchie, M.A., M.D., B.Sc. Reader in Pathology, University of Oxford. Third Edition, with 150 Illustrations. London: Young J. Pentland.

The illustrations are generally good and both the text and bibliography are commendable.

Laboratory Notes.

MALTOVA.

We have received samples of Maltova, a new food, prepared from extract of malt and the nutrient constituents of eggs. The combination is a happy innovation, in that together they form a highly nutritious and digestive food well adapted for administration to the young whose development lags behind, and in general to those whose recuperative powers are below normal.

The digestive and nutritive properties of a malt extract rich in diastase is well known and need not be dilated upon, but this particular food possesses nutritive qualities quite different and superior to mere extracts of malt for reasons which are obvious.

In virtue of its egg constituent, Maltova contains lecithin, an organic phosphorus compound which enters intimately into the composition of the brain and nervous tissues, and which, moreover, is now largely prescribed on the Continent for its tonic and regenerative effects on the nervous system.

Maltova has an agreeable and delicate flavour, and will be taken with avidity by children.

NEW INVENTIONS.

THE POCKET RESERVOIR CAUTERY.

Suggested by Dr. J. F. RUSSELL.

It is called "reservoir," because on heating, its body acquires sufficient heat to feed its point for a considerable time during use. It cannot get out of order, and it requires no apparatus outside itself except some heating source—a gas jet or a spirit lamp, for example, and its adjustment is so easy that it can be used like a pen, especially to destroy *nævi* with one application, where the use of acid would be dangerous or impossible.

In using the cautery, it is only necessary to extend the rod through its handle to the full length, tighten the screw, and make the cautery red-hot; then loosen the screw, drop the cautery back through its handle to the desired length, re-tighten the screw, and use. It is made by Messrs. Arnold and Sons, West Smithfield, London.

Medical News.

Alleged Assault by a Doctor.

DR. JOHN STAFFORD MELLISH, of Tetbury, had to defend himself last week before a special jury at the Oxford Assizes against a charge of assault, the plaintiff being a farmer whom he had caught, as he alleged, *in flagrante delicto* in his stables with his housemaid. The question turned upon the point whether he had employed more violence than was necessary, and this appears to have been admitted, but the jury, taking a human view of the circumstances, returned a verdict with one farthing damages, with costs against the defendant, so that the latter is probably "sorry he spoke."

A Defective Hot-water Bottle.

A CLAIM for damages caused by the bursting of a rubber hot-water bottle was tried last week at Liverpool. The plaintiff had purchased the rubber bottle, which on analysis proved to consist of a very inferior description of material. For the defence it was stated that a distinct warning was given against using *boiling* water,

and that the bottle was capable of resisting ordinary hot water. In their finding, the jury declined to find evidence of guarantee, or that the defendant was guilty of negligence, though they admitted that the bottle was not fit for use, and judgment was reserved pending a legal argument on the legal effect of these findings.

Notification of Infectious Diseases in France.

ACCORDING to the law just promulgated in France declaration and disinfection are declared compulsory in respect of typhoid fever, typhus, small-pox, chicken-pox, cholera, plague, yellow fever, puerperal infections, ophthalmia in the new-born, and contagious cerebro-spinal meningitis. Declaration is optional in respect of pulmonary tuberculosis, pertussis, pneumonia, erysipelas, and leprosy.

Death under Chloroform.

AN inquest was held last week at Westminster on a man, *æt.* 50, who had died under chloroform at St. George's Hospital while undergoing a second operation for appendicitis. The medical evidence was to the effect that death was due to heart failure of the nature of a coincidence, and a verdict in accordance therewith was returned.

Vital Statistics.

THE deaths registered last week in the eighty great towns of the United Kingdom corresponded to an annual rate of 17.8 per 1,000 of their aggregate population. The highest annual death rates per 1,000 living, as measured by last week's mortality, were:—From all causes, 28.8 in Tynemouth, 25 in Dublin, 21.0 in Wigan, 21.3 in South Shields and in Hastings, 21.4 in Newcastle-on-Tyne, 21.5 in Rochdale, 22.4 in Wallasey, 23.1 in Manchester, 23.2 in Bootle, 24.2 in Huddersfield, 26.4 in Hanley, and 20 in Belfast; from measles 5.9 in Wigan; from diphtheria, 1.2 in Northampton and in Blackburn, 1.5 in Merthyr Tydfil, and 2.5 in Hanley; from whooping-cough, 1.6 in Willesden and in Stockport, 1.8 in Rotherham, 2.0 in Great Yarmouth, 2.4 in Grimsby, and 2.7 in Smethwick; and from diarrhoea, 1.6 in Middlesbrough. Six deaths from small pox were registered in Liverpool, and 1 each in London, Manchester, and Leeds, but not one in any other of the large towns.

Trinity College, Dublin.

THE following passed the final examination in medicine, Hilary term, 1903:—Pringle, Seaton S., Holmes, John M., Sands, Thomas, L., Wilson, Thompson, F., M'Cutcheon, James, Marks, Alexander H., Ringland, William, P. Section B.—Nelson, Henry R., Wade, William M., Otway, Alexander L., Leech, John F. W. May, Harry O'H. H., Berry, Winslow, S. S., Clampett, Reginald W. T., Hallowes, Richard C., Bailey, Robert, Bryan, Rev. Richard, B., Vickery, Samuel, H.

Society of Apothecaries in London.

THE following candidates passed during the February examination:—

Surgery.—Beaumont, E. F. (Section I.), Beverly, E. M. (Sections I. and II.), Campbell, C. A. (Sections I. and II.), Gutermann, O., Nettell, J. P. (Section II.), Riley, S. (Section I.), Shanks, H. P.

Medicine.—Beverly, E. M. (Sections I. and II.), Bird, A. E. (Section II.), Campbell, C. A. (Sections I. and II.), Crockett, G. M. (Section II.), Humphreys, G. J. (Sections I. and II.), Pagonis, P. J., Shoosmith, L. S. (Sections I. and II.).

Forensic Medicine.—Beverly, E. M., Campbell, C. A., Crowe, G. A., Davies, T. S., Humphreys, G. J.

Midwifery.—Betts, K. G., Beverly, E. M., Bush, W. H., Campbell, C. A., Edwards, A. D., Finzi, N. S., Gosse, A. B., Wall, J. M.

The L.S.A. diploma of the society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—E. M. Beverly, C. A. Campbell, G. M. Crockett, T. S. Davies, O. Gutermann, G. J. Humphreys, J. P. Nettell.

Death of a Plague Physician.

THE death is announced of Dr. Yakato, a young practitioner who recently volunteered to attend persons suffering from the plague in Japan. His study of the disease has thus been brought to an abrupt conclusion.

Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial* and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CLINICAL *versus* PATHOLOGICAL DIAGNOSIS.

A CORRESPONDENT criticises the value of expert pathological opinion on the strength of a recent experience of his own which is not without its humorous aspect. A patient brought him, on a piece of paper, a fragment of tissue which, in colour and general appearance, suggested the possibility of its being a segment of *tenia solium*. He therefore prescribed an appropriate vermifuge, but, not feeling sure of the case, he forwarded the fragment in question to the pathological department of a London hospital and, in due course, was informed that it was not a piece of tapeworm but probably a portion of mucous membrane. He immediately wrote to his patient cancelling his prescription, but was informed by return of post that it was too late; that the patient had taken the draught and had passed some twenty feet of tapeworm.

Dr. S. F. S.—The matter is hardly within our province, but we will make enquiries.

THE ODOL TESTIMONIAL QUESTION.

The proprietors of Odol have written us respecting the remarks contained in our issue of January 21st, based on two complaints which we had received in regard to the publication of testimonials, and they have submitted to us the facts bearing on the circumstances, thereby satisfying us that, in the one case, the publication was due to an error on their part, as the particular testimonial should have come under another heading, an error which was promptly remedied by a suitably worded "erratum" contained in the entire issue of the booklet with the exception of the first few copies. The other case referred to, the published expression of opinion, was actually written by the author, and certainly expressed that gentleman's views upon Odol. Under the circumstances it must be conceded that, even in the absence of direct authorisation by the writer, the proprietors of Odol might have felt justified in considering it a *bona fide* and voluntarily given testimonial. We quite believe, therefore, that the proprietors of Odol acted in good faith and in an honourable manner, and that the allegation made as to the publication of "fictitious" testimonials is inappropriate, so far as this firm is concerned, and we withdraw it.

BIRTH IN A THEATRE.

According to *The Era*, last week, immediately after the fall of the curtain, at a London theatre, a lady in the stalls was delivered of a child. Fortunately such dramatic effects are rare in theatres. We trust mother and child are doing well.

Dr. POWER.—The clause in the Local Government Amendment Act is as follows:—In addition to the annual amount which may be contributed by a council of a county, or of a county borough, to a county infirmary or fever hospital under subsection (9) of section fifteen of the principal Act, the council may, if they think fit, contribute in any year the whole or any part of such further amount as may be certified by an auditor of the Local Government Board to be necessary to meet any deficit in the funds of such infirmary or hospital during that year. This provides the means of paying any increase in salary that the committee may be willing to grant, but the sanction of the L. G. B. must also be obtained. If the case is placed clearly before the latter body, such permission may be granted. All the points, however, of which you complain are matters which should have been taken into account when applying for the post. It is difficult to obtain reforms afterwards.

SOUTHWARK.—If possible, in our next.

Dr. O'REILLY.—Your letter affords a typical example of the hardships of the present Poor-law system, and should be an object lesson to all candidates for present appointments. As matters stand at present, you, or anyone in your position, would be most foolish to resign unless you had received a guarantee in writing that the salary would be paid by one specified Union. The question of pensions can only be settled by an Act of Parliament, and this will only be obtained by stopping the supply of candidates, and so making the present system of Poor-law Medical Service impossible. This has succeeded in the case of the A. M. S., and will succeed here, too, if tried steadily and persistently.

MITHRA.—There is no specific remedy for beri-beri. It is practically impossible that a man who is now, and has been for some years, resident in this country should develop the disease, unless he had come into contact with a case of it. The etiology of the disease is unknown. Pekelharig and Winkler found cocci in the blood, and Gerrard also succeeded in growing cultivations from it, but their results have not been generally accepted. See paper by Gerrard in "Trans. Academy of Medicine, Ire," vol. XVIII.

Meetings of the Societies, Lectures, &c.

LONDON.

WEDNESDAY, FEBRUARY 25TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Mr. J. H. Parsons: Ocular Circulation. (Arris and Gale Lecture.)

EPIDEMIOLOGICAL SOCIETY (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Discussion on the Panama Canal and the Introduction of Yellow Fever into Asia (opened by Dr. P. Manson, C.M.G.).

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover Square, W.).—5 p.m. Meeting.

HISTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Mr. C. Lucas: The Symptoms and Diagnosis of Stone in the Kidney.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Cheries Street, W.C.).—4 p.m. Mr. R. Harrison: Clinique. (Surgical.) 5.15 p.m. Mr. W. A. Lane: On Certain Abdominal Affections.

THURSDAY, FEBRUARY 26TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Cheries Street, W.C.).—4 p.m. Mr. J. Hutchinson, Jun.: Clinique. (Surgical.) 5.15 p.m. Dr. P. Stewart: Postures in Hysterical Paralysis.

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, Cavendish Square, W.).—8 p.m. Clinical Evening. Case of Myopathic Muscular Atrophy will be shown by Dr. Ascherson, Dr. Beavor, Dr. Buzzard, Dr. M. Clarke, Dr. Collier, Dr. Guthrie, Dr. Hutchinson, Dr. Ormerod, Dr. Pitt, Dr. Russel, and Dr. Taylor.

FRIDAY, FEBRUARY 27TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Mr. J. H. Parsons: Ocular Circulation. (Arris and Gale Lectures.)

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 p.m. to 9 p.m.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Cheries Street, W.C.).—4 p.m. Dr. T. Grant: Clinique. (Ear.) 5.15 p.m. Mr. H. L. Barnard: Acute Appendicitis.

Appointments.

CARR-WHITE, Major P., M.B., I.M.S., Clinical Assistant to the Samaritan Free Hospital for Women.

CLAPHAM, Lucy B., M.B.Lond., Assistant Anaesthetist to the New Hospital for Women, London.

DIMORE, Henry Bertram, L.R.C.P.Lond., M.R.C.S., Medical Officer for the Wroughton District by the Swindon Board of Guardians.

JARVIS, John, M.R.C.S., Surgeon to the Western Dispensary, Bath, vice Mr. John Davies.

LYELL, J. H., M.D., C.M.Glasg., Outdoor Surgeon to the Royal Infirmary, Dundee.

PALMER, Harold Lewis, M.R.C.S.Lond., L.S.A.Lond., J.P., Honorary Consulting Surgeon to the Montgomeryshire Infirmary.

PATON, E. L., M.B., C.M.Glasg., Visiting Surgeon to the Royal Infirmary, Dundee.

PEARSE, James, M.D., C.M.Edin., Medical Officer of Health for the Trowbridge (Wilts.) Urban District Council.

SANDALL, T. E., M.B., B.S.Cantab., Certifying Surgeon under the Factory Act for the Alford District of the County of Lincoln.

STIRLING, Robert, M.D.Edin., F.R.C.S.Eng., Visiting Surgeon to the Royal Infirmary, Dundee.

TAYLOR, W., M.D.Edin., Visiting Surgeon to the Royal Infirmary, Dundee.

Vacancies.

Belfast Maternity Hospital.—Matron. Must be a fully-trained and certificated nurse. Salary £60 per annum, with board, residence, &c. (see advt.).

Chesterfield and North Derbyshire Hospital and Dispensary.—Resident House Physician and Surgeon. Salary £120 per annum, with board, apartments, and laundress. Applications to the Secretary.

City of London Asylum.—Second Assistant Medical Officer and Pathologist. Salary £150 per annum, with board (except liquors), furnished apartments, washing, and attendance. Applications to Charles Fitch, Guildhall, E.C.

Durham County Asylum.—Second Assistant Medical Officer. Salary £180 per annum, with rooms, board, laundry, and attendance. Applications to the Medical Superintendent, Winterton, Ferryhill.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer. Salary £100 per annum. Applications to Thomas Hayes, Secretary.

North-Eastern Hospital for Children, Hackney Road, Bethnal Green, E.—Casualty Officer. Salary £80 annum, with lunch in the Hospital. Applications to the Secretary.

Owens College, Manchester.—Junior Demonstrator in Physiology. Salary £100 per annum. Applications to Sydney Chaffers, Registrar.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing. Applications to E. S. Baylis, J.P., 19, Moorgate Street, Rotherham.

Stockport Infirmary.—House Surgeon. Salary £100 per annum, with board, washing, and residence. Applications to the Secretary.

Staffordshire General Infirmary, Stafford.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing. Applications to the House Surgeon.

Births.

COOK.—On February 20th, at Mengo, Uganda, the wife of John Howard Cook, M.S., F.R.C.S., of a son.

HUNNARD.—On February 19th, at Nottingham Road, Mansfield, the wife of Arthur Hunnard, M.B., B.S., of a son.

Marriages.

GORDON-SMITH-NEWBERY.—On February 18th, at All Saints', Milton-Ernest, Bedford, Harry Gordon-Smith, M.A., M.B.Cantab., of 17, Dartmouth Park Road, N.W., only son of Percival Gordon-Smith, F.R.I.B.A., of Oakhill Road, Putney, to Amy Eileen, youngest daughter of Frederick Newbery, of Milton-Ernest, Bedford.

HOBART-GUEST-LANE.—On February 19th, at St. Finn Barr's Cathedral, Cork, by the Very Rev. the Dean of Cork, assisted by the Rev. Alan Lucas, Nathaniel Henry Hobart, M.B., 33, South Mall, Cork, to Edith, younger daughter of W. Guest-Lane, Sans Souci, Cork.

Deaths.

LATTEY.—On February 20th, at Dewsbury, Reading, Walter Lattey, M.D., formerly of Southam, Warwickshire, aged 63 years.

PERKINS.—On February 18th, at The Firs, Woking, Thomas Peregrine, M.D., late of Half Moon Street, Mayfair, W., in his 93rd year.

TURNER.—On February 19th, at Courtlands, Shanklin, Isle of Wight, Margaret, widow of S. M. Turner, F.R.C.S., of Newcastle, Staffordshire.

Original Communications.

THE DIAGNOSIS AND TREATMENT OF TUBERCULOUS DISEASE OF THE MIDDLE EAR AND ITS ACCESSORY CAVITIES. (a)

By WILLIAM MILLIGAN, M.D.,

Hon. Surgeon, Manchester Ear Hospital; Lecturer on Diseases of the Ear, &c., &c.

THE immense importance of an accurate and final diagnosis of tuberculous disease of the middle ear, both from the point of view of prognosis and of treatment, requires no accentuation. In every-day practice difficulties of varying magnitude surround the question of diagnosis, and my object at this moment is to place before you certain points which the experience of various observers has shown to be of value in helping to determine the existence or otherwise of middle-ear tuberculosis. In using the phrase "middle ear and accessory cavities," I include the tympanic cavity with its backward extension, the tympanic antrum, the adjoining mastoid cells developed around the antral cavity, and the whole course of the Eustachian tube from its tympanic to its pharyngeal orifice.

Tuberculous disease of the middle ear and its accessory cavities may be of primary or secondary origin. Up to the present moment most observers regard secondary tuberculosis of the middle ear as of much more frequent occurrence than primary tuberculosis. Secondary tuberculous disease of the middle ear occurs more frequently as a complication of tuberculous disease of the respiratory tract, and especially of the lungs, than as a complication of similar disease affecting bones, glands, abdominal viscera, &c.

From the otological point of view, the existence or otherwise of tuberculous disease of naso-pharyngeal adenoid vegetations is of the first importance. Given the presence of tuberculous adenoids, it is easy to see how readily the middle ear might become similarly infected. The evidence as to the existence of tuberculous adenoids is based upon the observations of comparatively few investigators. In a series of cases which I examined some years ago I found 16 per cent. of naso-pharyngeal adenoid growths of a tuberculous nature. A tuberculous process once started in the succulent adenoid tissue of young children may spread by simple continuity of tissue, and may ultimately locate itself in the mucosa of the tympanic cavity or its adnexa.

If careful histological examination of the parietes of the Eustachian tube be made, the tuberculous process may be seen affecting the mucosa and the submucous adenoid tissue, and extending in a definite line of march from the naso-pharyngeal to the tympanic cavity. More attention paid to this particular point would, I

believe, in all probability elicit the fact that naso-pharyngeal adenoids when tuberculous play an important rôle in subsequent tuberculous infection of the middle-ear cavities.

Nasal tuberculosis, although a distinctly rare condition, must not be ruled out of court in the consideration of this question. Tuberculous middle-ear disease as a complication of pulmonary phthisis may occur at any stage. Primary tuberculosis of the ear is stated by most observers to be of infrequent occurrence. When occurring as a primary affection it may be the result of a blood or of an aerial infection. My own experience has led me to the belief that as a primary infection it is not so uncommon as is usually supposed; that its site of origin is frequently within the cancellous spaces of the pars mastoidea—in fact, an osteomyelitis of the part—and that it is prone to remain as a circumscribed local process until a secondary and a septic contamination of the middle ear takes place.

Predisposing Causes.—The main predisposing causes are infection from association with tuberculous individuals, hereditary tendency to the catarrhal diathesis, improper and insufficient alimentation, unhealthy environment, the existence of any form of wasting disease—e.g., scarlet fever, diphtheria, scarlatinal diphtheria, &c.

Exciting Causes.—The more important exciting causes are the existence of tuberculous disease of some segment of the respiratory tract—e.g., lungs, larynx, or naso-pharynx—previous middle-ear disease, with an open perforation.

Tuberculous disease of the middle ear may run an acute or a chronic course. In the acute variety the deposition of miliary tubercles (occasionally to be observed through an intact membrane) leads to multiple perforations, rapid destruction of soft tissues, and rapid formation of granulomata springing from the mucosa covering the promontory. The very rapidity of the process would appear to give no time for involvement of bone. The process is fulminating and superficial, and rapidly assumes the characteristics of a mixed infection, owing to the invasion by various pathogenic organisms. Tubercle bacilli are at first fairly profuse in the exuded pus. In such cases the organismal warfare is carried on with great vigour. Pathogenic organisms, however, gain the upper hand, and discharge which at first may have been found to show fairly large numbers of bacilli will now be found to swarm with cocci, whilst evidences of distorted, ill-formed, and almost unstainable bacilli will be seen in the miniature panorama of the microscopic field. The chronic and atrophic form of tuberculous disease of the middle ear is, however, the type most frequently met with, and the one to which special attention should be directed. The channels along which bacillary invasion may take place are three in number—vascular, aerial, and mechanical. Vascular invasion may be through the general blood-stream, as in miliary tuberculosis or tuberculosis of bones. Infection along lymphatic radicles and lymph spaces may be demonstrated in cases of naso-pharyngeal origin with subsequent involvement of the mucosa and submucous tissue of the Eustachian tube. Aerial invasion may occur along the

(a) Read before the Otological Society of the United Kingdom

lumen of the Eustachian tube or through an already present perforation of the membrana tympani. Infection through an already existing perforation of the membrana tympani is no doubt possible, but probably is infrequent. Mechanical infection is to my mind also a possibility.

The symptoms of tuberculous middle-ear disease may be grouped under two headings—subjective and objective. The symptoms of acute tuberculous disease of the middle ear are somewhat anomalous. The occurrence of a middle-ear inflammation of medium intensity, and accompanied by considerable impairment of hearing in a subject of delicate constitution, might possibly suggest a diagnosis. It is only, however, by the discovery of multiple perforations or great destruction of the membrane, early and rapid formation of granulation tissue, early enlargement of the periotic ganglia, or early facial paralysis, that suspicion as to the true nature of the disease is usually aroused. The fact that such cases rapidly assume a mixed infective type tends also to mask an accurate diagnosis.

In the chronic and more usual form of the disease the main subjective phenomena are the occurrence of middle-ear inflammatory process with a variable degree of impairment of hearing, with a varying amount of subjective tinnitus, and a varying sense of fullness in the head and affected ear or ears, and an almost complete absence of pain.

The objective indications of the disease are referable to the effects produced by the deposition of bacilli within the mucosa of the tympanic cavity and to the subsequent ulcerative effects which are thereby induced. In certain rare cases miliary tubercles may be seen through a pale and semi-transparent membrane. Being deposited, as they in the first instance are, in the superficial layers of the mucosa, they appear as yellowish areas in a pale pearly gray membrane. Owing to the caseating of their central portions, they readily break down and form superficial ulcers. This ulcerative process extends to the deeper portions of the mucosa and subsequently to the underlying bone. When deposited upon the mucosa of the membrana tympani they tend to produce multiple perforations. These perforations, by their coalescence, produce ultimately great destruction of the membrana tympani. The special characteristics of tuberculous perforations are circular shape, pale, thickened, and indolent-looking edges, and general absence of reparative activity. It is claimed that tuberculous perforations are most frequent in the postero-superior segment of the membrane. Blake and Buch regard the occurrence of a painless perforation in the upper posterior quadrant of the membrane as pathognomonic of a commencing tuberculous process.

The discharge from the middle ear, which in the early stages of a tuberculous infection is thin and scanty, changes its characteristics when infected with mixed organisms, and becomes thick, creamy, and more profuse. In the early stages of the infection, when no bone lesion is present, it is odourless and, as a rule, free from admixture with blood. When succulent granulations appear, and especially when associated with an underlying carious process, blood-stained discharge is common. Granulations growing from a mucous infected with tuberculous elements are pale, flabby, œdematous, and friable. They may grow directly from an area of ulcerated mucous membrane, in which case they often attain considerable size, and fill up in part or in whole the cavity of the tympanum or the tympanic antrum. When originating from an underlying carious focus they must be classed as bone granulations, and are somewhat more friable than when growing from the mucosa itself, more vascular, and more prone to recur after removal. They are more frequently met with in tuberculous cases than in non-tuberculous. In 75 per cent. of my cases of tuberculous disease they have been a prominent feature, and in a certain number caseating areas have been observed on microscopic examination.

An objective indication of much importance is the early and readily detectable presence of bare bone. A distinct feature of tuberculous invasion of the middle

ear is the readiness with which the underlying bone becomes eroded. Not only does this take place at a much earlier stage than is usual in non-tuberculous cases, but it is prone to be more extensive, more rapid in its progress, and more likely to end in the formation of large sequestra. Owing to this early and, at times, extensive destruction of bone, facial paralysis is a symptom of frequent occurrence, and, if malignant—*e.g.*, sarcomatous—disease can be excluded, offers to my mind a very strong argument in favour of the underlying process being of a tuberculous nature. In 45 per cent. of my cases of proved tuberculous disease facial paralysis was present, whereas its frequency in non-tuberculous cases is probably not more than 2 to 5 per cent. In addition, it undoubtedly occurs as a much later symptom in non-tuberculous cases.

The extent to which the temporal bone may be destroyed without any objective evidence of what is actually going on is remarkable. I have on many occasions found practically the entire cancellous tissue of the mastoid process eaten away, leaving only a thin shell of more or less compact bone to preserve the underlying tissues. In one fatal case of double tuberculous otitis the two temporal bones were so eaten out by disease that only a thin shell remained upon which the middle fossæ were poised.

Carious erosion may, and frequently enough does, destroy the stapedio-vestibular articulation, and so opens up the cavity of the internal ear. Either in this way or by direct erosion into the cochlea the internal ear may become infected with progressive destruction of the contents of the labyrinth. Habermann, Schwabach, Gradenigo, and Brieger found in nearly 33 per cent. of the cases of tuberculous disease of the middle ear submitted to a post-mortem examination perforation in one or both of the labyrinthine windows. When this occurs infective processes are prone to attack the pia-arachnoid, bacilli being conveyed along the perivascular sheaths surrounding the terminal filaments of the stylo-mastoid artery to similar sheaths surrounding peripheral filaments of the internal auditory artery—the terminal branch of the basilar.

In my experience erosion of the outer table of the mastoid process is not so frequent in tuberculous cases as in non-tuberculous, and as a corollary from this subperiosteal mastoid abscesses are more frequent in non-tuberculous cases. On the other hand, I have met with quite a number of cases where, on making an incision behind the ear, the cortex was found perforated (although there was no suspicion of this beforehand), and the fistulous opening, sometimes as large as a sixpence, found to be filled up to the surface with a mass of creamy-white material of the consistence and appearance of putty. In fact, in some cases the superimposed periosteum appears to offer a more formidable barrier to the extension of disease than does the bone itself. In only two of my cases have I found a Bezold's perforation. Enlargement of the periotic ganglia is a most important indication. In non-tuberculous otitis media, excluding malignant disease, it is distinctly uncommon, and, when present, as a rule but few glands are affected. Such glands are tender if not actually painful to touch, are prone to vary in size with the virulence of the inflammatory process, and are more prone to induce a periadenitis.

In tuberculous processes early enlargement of glands is the rule. In fact, it is rare to find tuberculous middle-ear disease unaccompanied by enlarged glands. Such enlargement takes place also at an early stage of the disease. The infection spreads to surrounding glands until large masses and chains of glands are formed, often matted together, and exhibiting all stages of degeneration, caseation, suppuration, and calcification. When suppuration has taken place and a fistulous track has formed, the granulations lining it are pale, flabby, and œdematous. If healing takes place the resulting scar is depressed, irregular, and unsightly.

The clinical picture, therefore, presented by a case of suspected tuberculous origin differs materially from that presented by a non-tuberculous case. On the one hand, the process is distinguished by its latency, its asthenic type, its painlessness, its tendency to mul-

multiple perforations, extensive bone lesions, early facial paralysis, and early enlargement of the periotic ganglia; on the other hand, we have an acute sthenic process, accompanied by pain, fever, and reactionary symptoms, with no great tendency—at least, not in its early stages—to bone or glandular involvement or implication of the facial nerve, and with an inherent tendency to resolution and repair.

It must not be assumed that because a suppurative otitis media occurs in a tuberculous subject that therefore the aural infection is tuberculous also. Patients suffering from pulmonary or laryngeal phthisis frequently suffer from pathogenic middle-ear disease, the process often enough, however, running an abnormal course, probably due to the want of tissue vigour induced by the already existing pulmonary affection; nor, on the other hand, must it be assumed that because bacilli are not found in the discharge from the ear or in scrapings of granulation tissue that therefore the process is non-tuberculous. The actual demonstration of the bacillus, to my mind an essential and important factor in the final diagnosis of the case, is admittedly difficult, but, although admittedly difficult, is so important, both from the point of view of prognosis and of treatment, that it should never be neglected.

What, then, are the means by which this confirmatory and final diagnosis may be made? Examination of the discharge from the middle ear is usually unsatisfactory, as bacilli are extremely difficult to find. In cases of acute onset, however, and if examined at a very early stage, bacilli may be found in considerable numbers. In the more chronic form of the disease—the form much more frequently met with in practice—the almost invariably mixed infection which exists tends to destroy any existing bacilli, and at the same time to so distort and alter those which remain that their detection is difficult and uncertain. The removal of small tufts of granulation tissue and their subsequent microscopic examination is more likely to yield positive evidence. Frequently they will be found to contain bacilli, caseating areas, or giant or epithelioid cells. Another method of arriving at an accurate and final diagnosis when enlarged glands are present is to remove a gland, cut sections and examine for bacilli. In this connection it is of great importance that a young and early infected gland be selected. It is of little use examining old and caseating glands, as bacilli are rarely, if ever, found with such a high degree of pathological disintegration. A method which I have, however, tried, and with positive results, has been the aspiration of a glandular abscess with a fine exploring needle and the examination of the pus for bacilli. In the event of bacilli being found, either in sections of glands removed by operation or in pus from glandular abscesses, the inference, of course, is that the exciting cause for the glandular enlargement or abscess is of a tuberculous nature.

In cases of suspected tuberculous origin valuable information may at times be gained from an examination of sections of naso-pharyngeal adenoids.

The employment of tuberculin has not met with much favour in this country. Its indiscriminate employment in unsuitable, and too far advanced cases undoubtedly brought it into disrepute. When judiciously employed—that is, in an early lesion and before a mixed infection masks its true nature—it is useful, both from the point of view of diagnosis and of treatment. Very small doses should be used at first, and where there is a rise of temperature no further injection should be made until the temperature has fallen to normal again.

If such inoculations be conducted with proper antiseptic precautions, the information afforded is reliable. The main objection to the method is the difficulty of securing the necessary license and the interval of time which must elapse before a final decision can be arrived at.

Course of Disease.—In acute infections the disease runs a rapid course and ends fatally. As a rule such acute cases occur among those already debilitated by tuberculous processes elsewhere, and frequently among those in the last stages of pulmonary phthisis. The chronic and more usual types of infection run a slow, painless, and asthenic course. Exacerbations are

usually the result of secondary pathogenic infections. Many patients succumb to the effects of the disease or to complications induced by the disease. In other cases, however, energetic and well-directed surgical measures will undoubtedly succeed in eradicating what has been a localised tuberculous infection.

The complications which result from tuberculous middle-ear disease may for convenience be divided into those attacking intracranial structures and those attacking viscera.

I have already touched upon the danger of tuberculous middle-ear disease infecting the meshes of the pia-arachnoid by bacillary extension along perivascular lymphatic spaces. Other channels of infection are through eroded and ulcerated bone—*e.g.*, tegmen tympani, tegmen antri, groove of lateral sinus, &c.—whilst the tuberculous virus may also be conveyed along the perivascular sheaths of the carotid artery and jugular vein. The occurrence of intracranial abscesses is, in my experience at least, not very frequent in tuberculous cases. This is probably due to one of three causes: either the patients do not survive long enough to admit of the formation of secondary abscesses, or the destruction of bone which takes place so permits of drainage that the risks of secondary infections are minimised, or the fact that the pia-arachnoid membranes are more in the line of direct attack and more vulnerable than contiguous structures. In a certain proportion of cases the meningeal attack which carries off the patient suffering from tuberculous middle-ear disease is of a septic nature and due to a secondary infection by such organisms as streptococci, pneumococci, &c.

Recurrence of Disease.—In my experience fresh foci of bone infection are apt to crop up from time to time even after the case appears to have been cured. This may be due to tubercle lying dormant for a time and becoming lit up as the result of some incidental or accidental cause, or to the incidence of a fresh dose of infection from a primary focus in some other portion of the body.

Prognosis.—The younger the patient the greater the risks. Extensive involvement of bone, marked facial paralysis, copious blood-stained and fetid discharge, and masses of enlarged glands materially diminish the chances of recovery. Advanced pulmonary disease or advanced tuberculous infection of any other organ must necessarily render the prognosis grave quite apart from the aural condition. On the other hand, primary involvement of the ear, although always serious offers a much better hope of recovery provided persistent and painstaking efforts are made to eradicate any focus of infection which crops up. This may mean repeated operative interference, but final success will amply repay the surgeon's toil. At least 40 per cent. of my cases of proved tuberculous infection have succumbed to the disease, some from tuberculous or septic meningitis, others from pulmonary phthisis, intestinal tuberculosis, acute miliary tuberculosis, and general marasmus.

That tuberculous disease of the middle ear is more frequent than is usually supposed will, I believe, some day be fully recognised. Among infants and young children, especially among the poorer children of our large cities, the disease in my experience is painfully common. From 50 to 60 per cent. of my hospital patients below the age of six suffering from suppurative middle-ear disease owe their disease to the ravages of the tubercle bacillus. In adults the disease is undoubtedly much less frequent.

Treatment.—In cases of temporal bone tuberculosis occurring among patients suffering from advanced pulmonary phthisis or advanced tuberculous disease in any other portion of the body, operative interference is contra-indicated. On the other hand, however, retroauricular abscesses should be evacuated, and sequestra which interfere with the maintenance of free drainage removed for the sake of the general well-being of the individual. In cases of comparatively early pulmonary phthisis, where the general condition of the patient is good, much benefit will accrue from operation. Free removal of diseased bone and suppurating granulation

tissue and the provision of efficient drainage will tend not only to materially lessen the patient's discomfort, but also to give him a better chance of successfully combating the ravages of the tubercle bacillus. It is hardly necessary to add that in such cases attention should be paid to clothing, diet, and the provision of an ample supply of fresh air. Change of air, residence at the seaside or in moorland country, and the selection of suitable houses, &c., have all a place in the treatment of tuberculous disease of other regions just as in the treatment of tuberculous disease of the middle ear. In infants and young children, among whom tuberculous middle-ear disease is, unfortunately, frequently fatal, treatment must be conducted upon both general and local lines.

The question of local treatment is of paramount importance. The main indications are the employment of antiseptic treatment, the removal of diseased bone, the provision of free retro-auricular drainage, the removal of infected glands, and the treatment of concomitant nasal or naso-pharyngeal disease. Certain cases will, however, at once appeal to the surgeon as inoperable—viz., cases occurring among infants and young children suffering from marked debility, advanced facial paralysis, extensive bone disease, masses of enlarged glands, and copious foetid and blood-stained discharge. On the other hand, where the general condition of the patient is good, even although locally there may be extensive disease, operation is indicated. A point of importance in such cases is the advisability of dividing the operation into stages. For some time past I have been in the habit of dividing such operations into two and sometimes into three stages, upon the first occasion opening only a post-auricular abscess or suppurating mass of glands, on another securing free retro-auricular drainage, and on a third making a serious effort to eradicate the disease.

Where the facial nerve is completely paralysed, and where, in addition, the labyrinth is affected, my feeling is that the best line of treatment is to regard the condition as a tuberculous bone-abscess, and to clear out everything, even opening up the labyrinth very freely, regardless of the fact that it is an organ of special sense upon which the operator is working. The risks to the life of the patient when the labyrinth has become opened up are immensely increased, the infective process being prone to advance along the perinaural or perivascular sheaths to the pia-arachnoid membranes. In such cases the lesser of two evils should be chosen—the sense organ should be sacrificed in the hope that the life of the individual may be spared. Where 10 per cent. of the hearing-power remains, an attempt should be made to preserve it. In such cases the ordinary radical mastoid operation may be performed, and should the operator be successful in eradicating the whole of the tuberculous disease, a subsequent attempt may be made to graft the antrotympanic cavity.

Treatment of Enlarged Periotic Ganglia.—Infected glands should be removed, otherwise, even in the event of being successful in the eradication of the existing aural disease, the patient will still be liable to general tuberculous infection. Sinuses leading to infected and suppurating glands should be thoroughly scraped and swabbed with pure carbolic acid, lactic acid, or turpentine.

Treatment of an Existing Facial Paralysis.—The extreme unsightliness of the unfortunate possessor of a paralysed facial nerve makes it incumbent to attempt to remedy the defect so far as is possible. When severe the distal portion of the facial nerve may be united to the trunk of the spinal accessory as suggested by our distinguished member, C. E. Ballance, who has successfully accomplished it, the one disadvantage being that the patient, in order to smile upon the affected side of the face, has at the same time to shrug the corresponding shoulder. More recently Mr. Ballance has advocated the union of the facial to the hypoglossal nerve. The fact that the cortical centres of these two nerves are nearer to one another than are those of the facial and spinal accessory may possibly admit of a more ready and efficient response through their existing association fibres.

LUNACY AND THE LAW. (a)

By T. OUTTERSON WOOD, M.D. Durh., F.R.C.P. Ed.
M.R.C.P. Lond.,

Senior Physician, West End Hospital for Nervous Diseases
Welbeck Street, Cavendish Square, W.

MR. PRESIDENT AND GENTLEMEN,—It augurs well for the success of the action taken by the Conjoint Committee of the British Medical Association and this Association with regard to the amendment of the Lunacy Law, to enable cases of recent (incipient) insanity to be legally treated in private care without being certified as lunatics, that the Lord Chancellor inserted into his proposed Lunacy Bill a clause to meet our requirements, in the very terms I advocated at the annual meeting of the British Medical Association in 1896.

The importance of the subject must be my justification for bringing before this Association some features in connection with it, from a practical point of view.

I look upon the question for my present purpose as being divided into two sections only, for I intentionally leave the rate-aided class to be dealt with elsewhere.

Section I.—The proposal to extend the provisions of the present law, so that incipient cases of mental disorder may legally, and without delay, be brought under care and treatment without certification; and

Section II.—The suggestion that cases admittedly certifiable or even already certified, may be placed in single care, without the so-called stigma of certificates; or if already admitted into an asylum, they may be taken out and placed in the house of some relative or impecunious person, and kept there for profit, and not necessarily for cure, for it is not suggested that these patients may be curable.

Now, Sir, with regard to the first section, which deals with cases of recent (*i.e.*, incipient) insanity, I would divide them into two classes: (A) those who are amenable to reason and advice, who are absolutely uncertifiable, and who can to a great extent take care of themselves; and (B) those recent cases of a mild type in which the mental warp is more pronounced, who may require removal from home, who are almost certifiable, or who may even have harmless delusions, who require a certain amount of moral restraint, and who may object to the control necessary for their proper treatment. With regard to Class A, no alteration of the law is necessary; these patients are as capable of treatment outside the Lunacy Law as any ordinary medical case. I have to deal with a large number of them as out-patients at the hospital, and I have no difficulty whatever with them.

It is with regard to Class B that the law requires amendment, to enable us to obtain the legal control of the patient; and a system of notification seems to me the best to meet the requirements of such cases. This, however, is no new idea. I have for years advocated a relaxation of the present law in order that incipient, doubtful, or undeveloped cases might, under suitable conditions, and at the earliest moment be brought under that expert care and treatment which experienced alienist physicians know to be so necessary for the arrest of the disorder and the cure of the patient. Upon this point I am glad to think we are all agreed. It is the adoption of a principle that has worked well in Scotland for many years, and I know of no reason why, under proper conditions and with the necessary safeguards of skilled supervision, it should not work equally well in England and Wales, the order of a magistrate on this side of the border taking the place of the order of the sheriff, as in Scotland, for the legal detention of the patient for a definite period. There is, however, one point upon which we must insist, and it is that, wherever these cases are so placed, whether it be in a doctor's house or not, they shall be at once notified to the Commissioners and be placed under their official supervision as well as that of some skilled and independent local authority, appointed by the Board. Above all,

(a) Read at the General Meeting of the Medico-Psychological Association held at the County Asylum, Mickleover, near Derby, February 12th, 1903.

we must be certain that it shall not be merely a matter of boarding them out in so-called medical homes or private houses, kept by unqualified, inexperienced, and untrained persons, but that we shall have some guarantee that they will be cared for, and looked after, by those who have been trained in some recognised institution for the insane, or whose competence is assured by long experience, and who shall be approved of by the Commissioners; and, further, that they shall be nursed and attended not by hospital nurses who have had no asylum training, but that their nurses shall be asylum-trained, and, preferably, that they shall hold the certificate of the Medico-Psychological Association for proficiency in nursing and caring for those of unsound mind.

It is absurd to imagine for one moment that such cases as these can be properly treated by persons with no special knowledge of, or experience in, all the details of the moral control these persons require, and we must speak out with no uncertain voice in our condemnation of any attempt to minimise this, the most vital part of their treatment. The periodic visits of a consultant are practically useless as regards the supervision of these details which are of daily, even hourly, importance for the cure of the patient. This, of course, we cannot expect physicians, however eminent, to appreciate who have not made a special study of the care and treatment of mental disorders. It is the absence of this special knowledge on the part of the hospital physician which will permit him, on the one hand, to give these, the most difficult of all cases to manage, into the care of inexperienced people of limited means, or hospital nurses with no asylum training, who do not know what to do with them, who cannot understand the constant supervision and the unceasing vigilance they require, who are unable to anticipate a suicidal impulse or an outbreak of homicidal violence, and who will either rush in terror from the room at an outburst of excitement or will resort to the injudicious and unnecessary use of mechanical restraint; or, on the other hand, to give them up to the tender mercies of the keeper of some medical home or nursing institution who has never seen the inside of an asylum, who does not hesitate to send out hospital-trained nurses to acute mental cases, and untrained domestic servants as trained mental nurses! Gentlemen, I am speaking of things of which I have personal knowledge, and in my opinion, instead of the law being made more elastic with regard to these transparent frauds, it should step in and compel every nursing home or institution receiving such cases as these to be placed under some official supervision. If this were done we should hear less of the fatalities which are of such frequent occurrence, and which help to fill the columns of the daily Press.

While, therefore, we advocate the early treatment of cases of incipient insanity without certificates, let us endeavour to make sure it will be carried out in such an efficient manner that there shall be no excuse in future for the smuggling away of what are termed "borderland" case, or those deliberate evasions of the law which have been alluded to, and even boasted of, before the members of this law-abiding association, and which have in so many instances been followed by fatal results.

I will now turn to the second section of the subject, I mean the suggested extension of this system of notification for incipient cases, so as to make it applicable to chronic, certifiable cases of insanity, and to those already certified and living in institutions for the insane. This, in my opinion, would be a dangerous innovation. It is sad to reflect that at this time of day we are compelled to reiterate the arguments of our predecessors in this association against the un wisdom of such a retrograde step, and that the cruelty of mechanical restraint must again be brought forward to steady the minds of well-meaning but ill-informed philanthropists, and bring into bold relief the danger of giving a free hand to those impecunious persons who bombard us with applications for the care of this class of patient. One of these individuals who was anxious to obtain the care of such an one endeavoured to impress upon me the blindness and being crippled would not matter. I

presume if the unfortunate patient were blind, he could not see and criticise his food and surroundings, and if crippled, he could not escape, and would require less expensive supervision.

It has been suggested that the relatives of many certified patients should take them out of asylums because they are not dangerous to themselves or others and that they could undertake the care of such cases as well or even better than they could be cared for in an asylum without the stigma attaching to them of being certified lunatics. This, to my mind, is mere sentiment; nothing can alter the fact that the patients are insane, whether they are certified or notified, and whether the fastidious friends like it or not, the fact remains. My experience through a long series of years spent among the insane is, that more downright cruelty and neglect are often inflicted upon such patients by friends and relations owing to their ignorance and incompetence and through judgment giving way to feeling, than is possible under the splendidly humane treatment of such cases in our institutions for the insane, private as well as public, which are a credit and an honour to our country.

In support of this statement permit me to give you an account of a case which came under my notice a short time ago. A refined young lady of some twenty years of age, to save the stigma of certificates, was placed in charge of a hospital nurse in a so-called medical home, and because she was anxious to leave her room had an ingenious waistband buckled round her, to which was attached a half-inch rope sufficiently long to allow her to attend to the calls of Nature. This rope was firmly fastened to the bedstead. The nurse explained to me that but for this contrivance she would not have been able to leave the patient alone. Comment upon this case, which was one of certifiable insanity (and I certified her), but not dangerous to herself or others, is needless to members of this association. Take another case, which I also certified and sent to an asylum. A young lady, *æ*t. 22, was kept in a private house to save certification, in charge of a hospital trained nurse. She was in a state of acute mania, she had bitten the hand of the untrained lady in whose home she was detained, because she endeavoured to hold her down by force. This hospital nurse had an untrained young woman as an assistant. The patient was curled up in bed, jabbering incoherent nonsense, her hair unkempt, and she was unwashed and dirty, the room was barely furnished and most uncomfortable, and the window was strongly barred. As I was leaving the apartment I found each panel of the door excepting the one below the lock, was protected by a stout half-inch deal screwed securely over it, and the door showed evidence of violence. On examining the door from the outside, I found the panel under the lock was made to slide in a groove, with a knob on the outside, to draw it backward and forward, and over the space left when the panel was withdrawn were three strong iron bars. On inquiring of the nurse the use of this ingenious device, she informed me that it was to enable anyone sitting outside the room to see what the patient was doing inside! A convincing confession of incompetence! I confess to being somewhat shocked at such a condition of things occurring in the closing months of 1902. But, gentlemen, these are the evasions of the law we must expect to increase and multiply if the law is made "more elastic," with regard to cases of certifiable insanity, without adequate official supervision.

I do not wish to weary you with a recapitulation of further instances of the inhumanity of ignorance which are only too well known to us; but I venture to say that if the supervision of the certifiable insane in single care by the Commissioners is in any way relaxed, we shall soon have a recrudescence of those scandals which brought on to the Statute Book the Lunacy Law as it now stands. No perfunctory visitations of the physician can prevent them. Only within the last month I had three applicants for the post of nurse to a mental case, and in view of the question have raised of asylum-trained nurses being so necessary for the care of mental cases, permit me to de-

scribe to you the kind of persons these three applicants were.

No. 1.—A lady, quite untrained, but with some years' experience in private cases, wonderfully self-confident, and largely possessed of the audacity of ignorance. When I asked her if she were trained, she said "Oh, no! she didn't believe in trained mental nurses; they only irritated the patients." When I asked her what she would do if the patient happened to become violent, she said, "I would look at her; that would be quite enough"!

No. 2.—Another lady, untrained, who, when I asked her what she would do if the patient became violent, said "I would pull her arms back and tie them with a towel." I mildly suggested that that might not be enough, then said this untrained lady with a knowing look, "I would get a strap with hooks on it and hook them back"!

No. 3.—A tall, strongly-built lady, very much satisfied with herself and her powers, who would take any case, male or female. She was a trained hospital nurse whose only knowledge of mental training was gained by three months in a county asylum some years ago, and a few months in the insane ward of a workhouse. When I asked her what she would do if the patient became violent she said very decidedly, "I am quite competent to do some 'policemaning' if necessary"!

I thank that lady for the word "policemaning" it is so suggestive of truncheons and handcuffs and such like trifles! It is these and such as these gentle, untrained, impecunious ladies into whose care the friends of patients are asked to deliver them, *yet they all had testimonials from the friends and relations of former patients!* Then there is a further view of the subject which the following incident illustrates, and it is a pretty example of another method of evading the law. A friend of mine, at the request of his patient's relatives, called a physician in consultation upon a mental case which required certification to legalise the necessary control. "Oh, you must not certify it," said the physician; "call it hysteria, and you can do what you like with it." "That is all very fine," said my friend indignantly, "but the woman is a lunatic and ought to be certified." "Call it hysteria," reiterated the physician, and away he went, leaving my friend to treat a case of acute mania as hysteria! But very soon the crockery began to fly about, and the "hysterical" patient had to be promptly certified, and sent to an asylum. "Call it hysteria," indeed! We have arrived at a serious state of things if consultants, either unable or unwilling to recognise a case of acute mania, can bring themselves to call it "hysteria" in order that they may pander to the pride and prejudice of fastidious relatives who look upon this, one of the most affecting disorders that can afflict a fellow-creature, as a crime, or something to be ashamed of. Was it not rather the duty of a consultant to support the medical practitioner in his endeavour to induce the relatives of the sufferer to take a sane view of her malady, and do their best for her, rather than hand her to such untrained persons to be "policemaned" as a case of "hysteria"?

They who have spent their lives in endeavouring to ameliorate the condition of the insane must not stand by without protest and allow a reversion to those methods of barbarism which would be bound to follow any relaxation of the law without something more to protect the unfortunate patients than the mere visits of a physician, who may have no special knowledge of the care and treatment they require. Above all, we must be satisfied that those who are allowed to take charge of insane patients are properly trained and competent to do justice to their charge.

The point upon which the whole question hangs is that of adequate supervision. It is a very simple one. The Commissioners in Lunacy have all the facts in their possession. There is no need for any Commission of Inquiry about the Lunacy Laws. We know quite enough about them already. The appointment of deputy commissioners, together with local expert representatives of the Board in centres of the population, will, in my opinion, meet every requirement. By these means the vagaries of those who take charge of

cases of doubtful or confirmed insanity will be held in check, and the friends and relatives will be controlled and guided by the firm but kindly supervision of trained experts, who are qualified by long experience to guide and direct them in the right way.

NOTES OF A

CASE OF PERICARDITIS WITH EFFUSION ASPIRATED FOUR TIMES. (a)

By J. SINGLETON DARLING, M.B. Dub. Univ.,
Of Lurgan.

J. C., a gentleman, æt. about 30, was first seen on July 11th, 1900, in consultation with Dr. Moore, of Bangor. I learned that without being very robust he had always had fair health, and had been regular at his duties in one of the offices under the Corporation. His family history was good, but somewhat neurotic. Some months before he had been greatly disappointed at not getting some promotion he had set his heart on, and he had become depressed, eating and sleeping badly, and was noticed to be failing in health. He consulted no doctor till four weeks before I saw him, when he visited a consultant, who prescribed for him, and on the second occasion advised him to go to Bangor to get his strength up. His mother at once took a house there, and they went at the beginning of the month. Though breathless and weak, he went about until a few days before July 11th, when he was found fainting in the hall. Dr. Moore saw him, and found him alarmingly ill. When I saw him he was sitting up in bed, his face bedewed with sweat; he was gasping for breath, and could scarcely speak; his pulse was uncountable, and barely perceptible; in fact, he seemed to be dying, and it was with difficulty an examination of his chest could be made. There was dulness extending from the pericardium round the left side. No sounds could be heard over the cardiac region, nor could the heart sounds be heard in any other place. Dr. Moore concurring in the diagnosis of pericardial effusion, it was evident if the patient was to have any chance he must be relieved at once. An exploring needle was the only instrument available; we boiled it and cleansed the præcordia, and I plunged it into the fifth interspace one and a quarter inches outside the nipple line. We were rewarded by a jet of straw-coloured clear fluid. I carefully watched the flow lest air should be sucked in, and though there was evidently more there, when about thirty ounces had come I judged it prudent to withdraw the needle. The immediate effect was most gratifying; the pulse became fair, the dyspnoea became much less, and in a short time it became possible to examine the patient. He was anasarcaous, there was a good deal of fluid in the peritoneal cavity, the liver reached almost to the level of the umbilicus, and seemed to fill the upper part of the abdomen. It was ascertained that he was passing less than twenty ounces of urine in twenty-four hours; this was free from albumin. He was taking very little food, and as he was a vegetarian and full of fads the problem was not easy. We put our feet down about the vegetarianism, and laid out a dietary plan which was tolerably well adhered to. It would be tedious to mention the changes of medicine; suffice it to say that in the course of the treatment every cardiac and general tonic, every stimulant, and every diuretic in or out of the "Pharmacopœia" that seemed likely to be of any use was tried, and with this I shall dismiss this part of the subject, as none of them seemed to exercise much influence on the disease.

On the 17th I saw him again, and Dr. Moore informed me that the day after the tapping a mitral murmur could be heard, and that the heart sounds were fairly distinct. The daily urine had considerably increased, the anasarca and ascites were less, the liver had appre-

(a) Read before the Ulster Medical Society, January 19th, 1903.

ciably diminished, but gradually the heart sounds had disappeared and now again all was silent. I aspirated through the same space as before, and withdrew 62 ozs. (measured) of fluid. As the cavity emptied the heart could be felt pulsating against the blunt end of the cannula and the movement of the protruding end noticed. When the sac was emptied the murmur was audible, but the sounds were distant and indistinct. The pulse dropped under 120, and was of fair tension. On the 24th I aspirated 35 ozs., and on August 2nd 26 ozs. During these three weeks the patient made fair progress; the ascites almost disappeared, there was but little anasarca, and the kidneys continued to act fairly; but the liver still remained large. On August 8th there was manifestly fluid in the left pleura with resonance in places as if the lung were adherent there. I aspirated 80 ozs. of sero-purulent fluid, introducing the trocar at the angle of the scapula, and on the 17th I aspirated 93 ozs. from the same pleural cavity. About this time progress was interrupted by a severe attack of diarrhoea, and after this there was a tendency for the anasarca to increase, and there was again more fluid in the peritoneal cavity. The heart sounds remained distant, but there was no evidence of fluid in the pericardium. There was not much re-accumulation in the pleura. He very gradually got a little strength; the dropsy fluctuated, but did not go away, nor did the liver margin go higher than two inches above the umbilicus. On October 13th he was taken home to Belfast in a carriage, and Dr. McKisack took charge of him. I saw the patient several times afterwards with him, and later on with Dr. Robert Boyd. He slowly sank and died without any new symptoms developing.

Clinical Records.

CASE OF ACUTE LYMPHATIC LEUKÆMIA. (a)

By W. L. ASCHERSON, M.B., and H. D. ROLLESTON, M.D.

LUCY O., æt. 7, was admitted on February 17th, 1903, suffering from debility, pallor, and shortness of breath.

Family.—Is one of five healthy children. Father and mother healthy, but the latter had had several miscarriages. None of the children are prone to epistaxis. None of the family have been abroad. A full term child, breast-fed, always healthy until the present illness. Never known previously to bleed from the nose or to bruise readily, or to be pale.

Present attack.—On waking one morning the mouth was seen to be drawn up to the left side, and opening the mouth was difficult. Fluid food introduced into the mouth dribbled away, and the child seemed ill, dull, and apathetic. Next day, while playing, she fell from a toy horse and hurt her shins, and her mother said she was surprised at the rapidity and extent of the bruising. The child continued to be apathetic, and grew increasingly pale and weak. The facial symptoms disappeared twenty-four hours after they were first noticed. The day before admission she was seen in the out-patient department, when her temperature was 102.8°. The right side of the neck was painful, but there were no lumps in the neck. The spleen was enlarged. No facial palsy was observed. The child returned home to come up for admission the following day. That evening she had violent epistaxis and bleeding (it was reported) from the throat; bleeding continued all night through.

State on admission.—The child was fairly nourished, tired and apathetic-looking, and distinctly anæmic. There were some bruises on the shins, the result of trauma, and one on the left arm unaccounted for. No purpuric spots of any kind. Slight bleeding (oozing) still from the gums. No sign of epistaxis. A small conjunctival hæmorrhage was noticed in the right eye. Tongue was clean. Teeth defective, but not carious. The breath was foul, and had the characteristic smell

observed in these patients of decomposing blood. The tonsils were much enlarged, and the right showed evidence of a morrhage. There were enlarged glands on both sides of the neck (anterior and posterior triangles) and in the left axilla. The enlargement was only moderate, and the glands were freely movable. The glands in the groins were abnormally palpable. There was no manubrial dulness or evidence of enlargement of the thymus. The lungs were abnormal, but the heart showed evidence of moderate dilatation.

Abdomen.—Showed moderate enlargement of the spleen; the organ was felt three inches below the costal margin on inspiration; the edge was soft and rounded; notch not felt; the organ seemed of fairly soft consistence. Otherwise the abdomen seemed normal. No friction could be heard over spleen. There was no evidence of tenderness anywhere on pressure over the bones, and the special senses were intact. The urine contained a large deposit of unpigmented lithates, and was very pale in colour; otherwise normal.

Blood: Red blood-corpuscles.—Per cmm. 2,320,000; some poikilocytosis and irregularity in size of the individual corpuscles. One normoblast seen in a stained film. **Hæmoglobin.**—30 per cent. **Leucocytes.**—Total per cmm. 60,000, of which polymorphonuclear numbered 3.3 per cent., hyaline leucocytes 1.8 per cent., lymphocytes 95 per cent. No other forms were detected. The lymphocytes were for the most part large and showed characteristic fraying of the edges. In some cases budding and great irregularity in shape. Many particles of lymphocytic protoplasm were seen free in the blood.

The Out-Patient Departments.

TOTTENHAM HOSPITAL.

CASES FROM THE DERMATOLOGICAL CLINIC.

UNDER THE CARE OF G. NORMAN MEACHEN, M.D.
M.R.C.P. LOND. AND EDIN.

1. *Aberrant form of Psoriasis, simulating a Syphilitide.*—A married woman, æt. 42, came with an eruption upon the dorsum of the right hand and the outer aspect of the right knee, which had been present for six months. Two years ago she had a similar "breaking out" in the same situation, when she was treated at another hospital. Itching was very distressing. She had not had any previous illnesses or worry of any kind. The lesion on the hand consisted of dark red patches, somewhat coalescent, slightly scaly and not infiltrated. The single lesion over the external tuberosity of the right tibia was circinate in outline, of a brighter red than that on the back of the hand, and covered with whitish scales, which, on picking off, left a raw surface upon which were seen minute hæmorrhagic points. No other lesions were present anywhere else. The tongue was pale and flabby, and the fauces normal. The patient gave no history of rheumatism or syphilis. She had had thirteen children and two miscarriages. Dr. Meachen remarked that the patches on the hand could not be distinguished at sight from a tertiary eruption, but when one came to feel it, the absence of anything like infiltration was very striking. On the other hand, the patch on the leg was typical of psoriasis, although external to its usual site, *viz.*, over the ligamentum patellæ and tubercle of the tibia. It was very necessary, however, to be on one's guard against supposing that because a scaly eruption appeared upon situations other than the front of the knees and backs of the elbows, the favourite localities for psoriasis, therefore it could not be ascribed to that disease. The patch on the leg might be mistaken for a seborrhœic dermatitis, but it was of a deeper tint. As against the diagnosis of syphilis was the very important objective sign of absence of infiltration, and the subjective symptom of intense itching, which was rarely associated with specific eruptions. Lichen planus was also negated by the scalliness, the absence of outlying lichen papules in the neighbourhood of the main patches or in other

(a) Case shown at the Clinical Society, February 27th, 1903.

tuations commonly chosen by that disease, such as the flexor surfaces of the wrist, or about the knees or shoulders, and the colour, which in lichen was generally darker, duller, and more violaceous.

Under the application of a weak creolin lotion and a salicylic acid ointment of 20 grains to the ounce, the lesions gradually faded away, but, as if in confirmation of the diagnosis, others of a nummular character quite typical of ordinary psoriasis made their appearance upon the limbs and trunk. The patient was also given the *mist. ferri aperiens* three times a day.

2. *Pruritus Hiemalis with Xeroderma*.—A dairyman, married, *æt.* 45, complained of itching of the skin all over, worse in cold weather and especially on undressing before going to bed. The irritation had lasted for six years, and quite disappeared in the summer. His general health was good. On examination, the skin of the trunk was seen to be dry, harsh, and absolutely devoid of moisture. The normal lines of the skin were intensified. There was a slight degree of erythematous eczema on the forearms, where the roughness was also most marked. The urine was phosphatic, sp. gr. 1028; albumin and sugar were absent.

Dr. Meachen pointed out the very close association of the morbid conditions present in this man. What might be called "tendencies to eczema" were here latent, such as dry skin, erythematous reaction to cold air, only waiting for a suitable provocation to develop into the disease proper. In chronological order, there was first the mild degree of congenital xeroderma, next the pruritus owing to the loss of vaso-motor control, and to defective nutrition and lubrication of the skin resulting in a slight eczematous outbreak. To relieve the itching, a weak alkaline and creolin bath was ordered together with the *ung. zinci cum plumbo*, and to restore vaso-motor tone, *mist. ferri et quin.* For the forearms, gr. v. of ammoniated mercury were added to the ointment. Dr. Meachen said that there were two points of great importance to be observed in the general treatment of *pruritus hiemalis*, *viz.*, inspection of the under-linen worn, with advice as to its change, if necessary, and the careful selection of a suitable soap. This patient was wearing woollen clothing next his skin, and had been using a patent coal-tar soap. He, also had recourse, upon one occasion, to one of the largely-puffed varieties of soap which profess to "cure all skin diseases." He was advised to wear thin cotton material with flannel or wool over it, and to use fine oatmeal in tepid water for his forearms together with a superfatted menthol soap for the rest of the body.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

CLINICAL EVENING.

MEETING HELD FRIDAY, FEBRUARY 27TH, 1903.

Mr. HOWARD MARSH, F.R.C.S., President, in the Chair.

DR. LEONARD S. DUDGEON showed

THREE CASES OF VOLKMANN'S CONTRACTURE.

Case 1.—Child, *æt.* 5. Fracture of right upper arm near the elbow-joint in December, 1900. Treatment.—Plaster splints with the arm in flexed position. Within twenty-four hours fingers were swollen, cyanosed, and cold. Splints were not removed for four days, possibly owing to the absence of pain. Large pressure sore on flexor aspect of forearm. Hand and fingers in the typical position. Sensation normal. Electrical reactions practically normal. January, 1903.—Shortened forearm, which is strongly pronated. The position of the hand and fingers is still quite typical. Movement has improved. Treatment for two years.—Passive movements and massage daily. Faradism three times weekly. Result.—Very slight improvement. *Case 2*.—Boy, *æt.* 9. Injury to the left forearm two and a half years ago. Anterior and posterior splints for three weeks. No pain. Arm and hand

were cold and cyanosed, fingers in typical position, pressure sore. Several operations with no result. March, 1901.—Patient was brought to St. Thomas's Hospital. Electrical reactions showed partial R.D. in the ulnar nerve and muscles, and also in the posterior interosseous group. Partial motor and sensory paralysis in these regions. Treatment.—Massage daily. February, 1902.—Electrical reactions normal. Fingers and hand as before, but no ulnar or musculo-spiral paralysis. Operation by Mr. Clutton.—Resection of half to three-quarters of an inch of both radius and ulna from the posterior aspect of the middle of each shaft. Both wired. March 25th.—Bones united. Massage daily. Result.—Great improvement. *Case 3*.—Boy, *æt.* 8. Injury to the left forearm in December, 1901. Anterior and posterior splints for five weeks. No pain when splints were removed. Arm was shrunken, fingers contracted, and sloughing sore on forearm. September, 1902.—Child was brought to St. Thomas's Hospital. Hand and fingers in typical position. Electrical reactions normal. Scar on forearm. Skiagram showed no sign of an old fracture. October, 1902.—Mr. Clutton excised three-quarters of an inch from radius and ulna, wired ends. November 1st.—Good union. Massage daily. Result.—Great improvement.

DISLOCATION OF THE LONG TENDON OF THE BICEPS.

Mr. H. BETHAM ROBINSON showed a patient, *æt.* 27, who had the head of the left humerus excised in St. Thomas's Hospital on September 19th, 1900, by the late Mr. Anderson for recurrent dislocation. This had occurred nine times in the preceding three years. The result had proved most satisfactory. He came under my care at the same hospital at the beginning of this month, and gave the following account:—Six months ago he fractured the right clavicle, which united rapidly. On January 3rd last he fell off his van, hitting the front of his shoulder against a sharp corner. He then noticed the arm could not be brought properly to the side, and was in the position it has assumed several times since. The condition has varied since the accident, being sometimes better and sometimes worse. The patient, however, himself speaks of it being dislocated like the other one was. The position the arm takes is characteristic. The humerus is abducted and inwardly rotated to a slight extent; the shoulder-joint being then fixed, attempted movement is attended by rotation of the scapula. The head of the humerus can be distinctly felt in the axilla, and seemingly more prominent against the front of the capsule than normally. When it is "out" there is complaint of some tingling in the fingers generally. The malposition can be easily rectified by, after fixing the scapula, bringing the elbow forward, thus relaxing the biceps, and then rotating outwards. The condition is apparently associated with an abnormal laxity of the joint capsule, and an increased play of the tendon in its groove. In abduction with inward rotation the tendon slips over the great tuberosity, and at the same time the head of the bone is brought up against the front of the capsule at the anterior margin of the glenoid cavity.

Mr. GOULD suggested that the abnormality might be due to a hypertrophied synovial fringe.

The PRESIDENT was not convinced that it was dislocation of the long tendon of the biceps which generally took place inwards and not outwards. The case, he urged, should be thoroughly investigated.

Mr. BETHAM ROBINSON, in reply, thought the joint might be explored, but asked what ought to be done if it proved to be a dislocation of the tendon. He did not think it was indispensable to remove the head of the bone as on the other side.

VARICOSE INTERNAL SAPHENA VEIN IN A CHILD.

Mr. THOS. H. KELLOCK showed a girl, *æt.* 7, in whom there is considerable enlargement of the right internal saphena vein at the upper part, first noticed accidentally about a year ago; the course of the vein seems to be slightly abnormal, passing rather far towards the inner side of the thigh. Varicosity is also noticeable at the inner side and front of the patella, behind the internal malleolus, and over the inner side of the foot. No cause could be discovered.

Mr. GOULD said he had never seen varicosity in so young a female patient, though varicocele was met with in male children. He thought this condition supported the view that varicosity was not due solely, or even chiefly, to increase in venous pressure, but rather to over-development of the venous tissue akin to venous nævus.

Mr. HARRISON CRIPPS recalled the case of a girl, æt. 15, who had enlargement of the whole limb, but in her case there was also involvement of the lymphatics. In the author's case he remarked that the limb was slightly longer and the foot somewhat bigger than on the other side; in fact, he looked upon it as a case of incipient gigantism.

Mr. KELLOCK, in reply, admitted that the limb was about a quarter of an inch longer than the other, but there was no indication of the lymphatics being involved. He proposed to remove a piece of the vein above.

Drs. W. L. ASCHERSON and H. ROLLESTON showed a case of "Acute Lymphatic Leukæmia" which will be found on page 215.

Dr. ROSE BRADFORD questioned whether the case was really acute and suggested that it might be a case of some standing in which the symptoms had suddenly become more prominent.

Dr. ROLLESTON pointed out that the patient had markedly improved under treatment.

SYRINGOMYELIA WITH DISSOCIATIVE ANÆSTHESIA, ATROPHIC JOINTS, MUSCULAR ATROPHY, AND EXAGGERATED KNEE-JERKS.

Dr. A. E. RUSSELL showed a man, æt. 50, with well-marked atrophic arthropathy of the left wrist and carpal joints. Both shoulders creak on movement, and the left is apt to swell on attempting to work. The dissociative anæsthesia is distributed over both hands and arms, neck, scalp, and trunk down to the level of the fifth thoracic segment. There is considerable muscular atrophy of some of the intrinsic muscles of the right hand, especially of the abductor indicis. The knee-jerks are greatly exaggerated, but his gait is not spastic.

Mr. BOWLBY recalled a case in which the patient complained of pain &c., in the shoulder, associated with characteristic destruction of bone, but this destruction bore more on the parts external to the joint. He suggested the desirability of obtaining a radiogram of the joint.

Dr. RUSSELL, in reply, said the rays showed considerable bony changes.

CEREBRO-SPINAL MENINGITIS WITH OPTIC NEURITIS.

Dr. W. PASTEUR showed a female patient, æt. 22, of good family history. Her previous health good; no evidence of syphilis. Chlorosis lasting nine weeks early in 1902. Her present illness began with severe occipital headache, radiating forward to temples and down the neck. On September 17th severe pain in small of back, unable to move in bed; vomited on 18th and 19th, and on two occasions after admission. Shooting pains of varying intensity in arms and legs since onset of illness. Squint in left eye and prominence of both eyes on September 23rd. Sleeplessness from the beginning, numbness and tingling in fingers since middle of September. On admission, October, 1st, 1902.—Marked paresis of arms and legs (electrical reactions normal). Rigidity of neck muscles; no retraction. Gait very unsteady and feeble, but not staggering. Knee-jerk absent on right, just perceptible on left side. Plantar reflex normal. Kernig's sign present (October 10th). Babinski's sign: flexor response (?). Sphincters unaffected. Troublesome constipation throughout illness. Much tenderness and pain over cervical spine and upper dorsal vertebræ. Headache constant but slight, worse at night. Head always bent forwards on chest. She began to improve after October 22nd. Sight totally lost at this time. Optic neuritis beginning to subside on November 4th with slight recovery of vision. On December 1st, pupils

reacted slightly to bright light, but she cannot tell light from dark, and does not see an electric light when held up close to her face; is able, however, to distinguish a hand or book, especially if moved to and fro. January 19th.—Marked atrophy of both discs. Can find her way readily about the ward, and recognises the shape of objects without much difficulty—better against a dark background than against the light; is still unable to see the electric light held before her face, or to be sure of the position of the windows. Has almost completely recovered muscular power, and is practically restored to health. February 22nd.—On her return from the convalescent home vision has improved slightly. Can locate the ward windows correctly, and sees the electric light as readily as a more feebly illumined object, but the perception is only momentary, and immediately lost unless the light is moved, whereas the perception of the hand gains in distinctness as she continues to look at it. Both knee-jerks are still absent, otherwise she is in good health.

CASE OF WEBBED ARM.

Mr. RAYMOND JOHNSON showed a lad, æt. 6. The anterior fold of the right axilla is prolonged downwards in the form of a web which passes upwards from the inner side of the elbow to the chest at the level of the third costal cartilage, 2 cm. above the nipple. The pectoralis major is either absent or represented merely by a few fasciculi of the clavicular portion. In the free border of the web can be felt a slender fibrous cord ending below at the internal condyle of the humerus, and at its other extremity terminating in a muscular fasciculus attached apparently to the second costal cartilage (chondro-epitrochlearis muscle). There is impaired development of the whole upper extremity, and the four inner digits are webbed. The right scapula is smaller, and lies at a higher level than the left.

Dr. ROSE BRADFORD referred to a patient of Mr. Tweedy's who could not distinguish between light and dark, though he could distinguish form. He thought this curious condition had been described by certain German observers.

GRAVES' DISEASE IN FATHER AND SON.

Dr. H. BATTY SHAW showed a railway inspector, æt. 46, has been suffering from weakness for the last four years. Exophthalmos of slight degree was noticed a little over two years ago, and a month or two later the neck was found to be swollen. He is a very nervous subject, and is frequently troubled with palpitation. There is tachycardia (pulse rate 100 to 112), tremor of the hands, retraction of the upper eyelids, and von Graefe's sign is well marked; flushing of the face is common, and the skin generally is moist. The enlargement of the thyroid gland is larger on the right side than on the left. His son, æt. 21, has always been rather nervous, and there appears to have been for several years some prominence of the eyeballs. Nearly two years ago he met with a rather severe bicycle accident, and since then has noticed marked palpitation, and he says the eyes have been more prominent since the accident. The pulse rate is about 120 to the minute, there is marked tremor of the hands, especially the right. The eyes are prominent and equally so. There is enlargement of the thyroid gland; von Graefe's sign is absent. The skin is moist, and the apex-beat of the heart is diffuse. The urine is clear as a rule, but occasionally urates have been found in abundance. Specific gravity 1017—1026; acid; no sugar. Albumen is present, sometimes as a mere trace; sometimes a well-marked cloud is present. No other proteid fat can be demonstrated. He passes water three or four times at night.

Dr. SIDNEY PHILLIPS said he had met with the disease in mother and daughter. He had seen the case of chyluria before, the chyluria having ceased in 1901.

Sir HUGH BEEVOR showed skiagrams of a case of pneumothorax which showed the condition of the parts very clearly.

HARVEIAN SOCIETY OF LONDON.

CLINICAL MEETING HELD FEBRUARY 19TH.

Dr. W. WINSLOW HALL, President, in the Chair.

Mr. T. CRISP ENGLISH showed a case of "Paget's disease" of the left nipple in a woman, *æt.* 56. The patient was under the care of Mr. Dent, at St. George's Hospital. The disease started eighteen months ago as a red spot just above the nipple, and now shows an oval red patch surrounding the nipple, $1\frac{1}{2}$ in. by 1 in. in diameter. The margin was well defined, and the surface covered with fine scales. There was distinct induration, but no enlarged glands in the axilla.

Mr. ROUGHTON said that Paget's disease is so frequently a precursor of carcinoma of the breast, that he considered it the duty of the surgeon to remove the breast with a wide area of skin, and to clear out the axillary contents.

Dr. HENRY DUTCH suggested treatment by the X-rays, with free removal of any enlarged glands in the axilla.

Mr. JAFFREY said he agreed with the diagnosis, but that he felt some thickening in the axilla, which he thought due to enlarged glands. He recommended free removal of the breast, and of the contents of the axilla.

Mr. CAMPBELL WILLIAMS also agreed with the diagnosis, and recommended radical treatment, particularly as the disease had already existed eighteen months.

Dr. E. CAUTLEY showed a man, *æt.* 28, with "hypertrophic paralysis." Apparently no symptoms were noted until he went into the Russian army seven years ago. He was thought to be malingering, but as "kicking" did not prove curative, he was given six months leave. He did not improve, and was finally discharged. He complained of inability to do his work on account of weakness. He stumbled a little, and had difficulty in getting upstairs. The calves measured $17\frac{1}{2}$ ins. in diameter, and were very hard. Knee-jerks were absent. The vasti were a little wasted, but no other muscles were involved. The case was interesting on account of the age of the patient, the limitation of the disease, and the comparatively slow progress.

Dr. JAMES TAYLOR remarked that the case was very interesting as forming a link in a chain. He himself had known one case in which the signs and symptoms had only developed at the age of eighteen. Previous to this the patient had not only been able to walk, but had actually been an athlete, and had won prizes for running. Another case he had seen at the age of forty-three, and the patient had never been able to run. He remained practically unchanged, a typical case of pseudo-hypertrophic paralysis, until his death from pneumonia at the age of fifty. These cases seemed to illustrate a condition in which there was probably an inherited weakness or defect in the muscular tissue, which might become obvious at any age, and progress with varying rapidity.

Mr. JAFFREY showed a man, *æt.* 56, with an injury to the elbow of long standing with great deformity but with good movement. He was able to carry on his work without difficulty as a Covent Garden porter.

Mr. P. LOCKHART MUMMERY thought the case interesting, as showing how complete the recovery might be as regards movement and utility after injuries of joints in which mal-union has occurred. He also drew attention to the treatment of fractures of this nature near the elbow-joint, by full flexion with fixation in that position with or without splints.

Mr. ROUGHTON showed a youth with dislocation of the right shoulder and right hip, and with deformities of many bones, including the lower jaw. There were scars in the region of all the bones affected, and the condition was probably due to chronic septic infection as an infant.

The case was discussed by the President.

Mr. JAFFREY showed a specimen of a testicle, which before removal had been diagnosed by every one who saw the patient as one of tuberculous epididymitis, but which proved on removal to be rapidly growing sarcoma. A secondary deposit in the lumbar glands

was recognised within a fortnight of removal of the organ.

ROYAL ACADEMY OF MEDICINE IN IRELAND.
SECTION OF STATE MEDICINE.

MEETING HELD FRIDAY, FEBRUARY 20TH.

The President, Dr. NINIAN FALKINER in the Chair.

In a brief address the PRESIDENT reviewed the "Nomenclature of Diseases and Causes of Death," from the period of William Cullen, of Edinburgh, up to the year 1901, when Dr. Tatham's modification of the nomenclature of diseases (1896) was adopted for the official reports on vital statistics for these countries. In the course of the address, he appealed to the medical profession to consider the importance of giving a well-defined and accurate "cause of death" when framing the certificate, as it was on this testimony, and this testimony alone, that the value of the medical statistics of the nation depended.

After the conclusion of the address, the following resolution was proposed by Dr. BEWLEY, seconded by Dr. PARSONS, and passed unanimously:—"That in the opinion of the Section of State Medicine of the Royal Academy of Medicine in Ireland, it is advisable that the department of the Registrar-General of Ireland should be represented on the Nomenclature of Diseases Committee at present sitting in London."

Dr. MARTLEY exhibited a specimen of soup made in a tin-lined copper boiler, which, owing to the tin having worn away in places, was largely contaminated with copper. There was a thick black precipitate in which alone the copper was found, the clear fluid above being quite free from it.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING AT THE MEDICAL INSTITUTION, LIVERPOOL,
FRIDAY, FEBRUARY 20TH.

Dr. J. E. GEMMELL, President, in the Chair.

The following card specimens were shown:—

Dr. W. E. FOTHERGILL.—Hyperplasia of thyroid gland from fœtus in a case of eclampsia. Broad ligament cyst.

Dr. T. ARTHUR HELME.—Uterus showing "cystic degeneration" of cervix.

Dr. E. T. DAVIES.—A series of fibro-myomata of uterus.

Professor A. M. PATERSON.—Uterus from a dissecting room subject, showing a utero-vaginal septum.

Dr. LLOYD ROBERTS (Manchester) showed an ovarian tumour which, with its contents, weighed 30 lbs. It was removed from a woman, *æt.* 60, who fifteen years previously had suffered from a fibroid polypus. After the removal of the latter menorrhagia had persisted for some years. Clinically, there appeared to be both a uterine fibroid and an ovarian cyst. Operation revealed a large ovarian tumour containing sixteen pints of brownish grumous fluid. The more solid part of the tumour was simply a thickened part of the fibrous cyst wall.

The PRESIDENT inquired whether any ascites was present?

Dr. E. T. DAVIES (Liverpool) remarked that the case resembled that of a patient whose tumour was shown on the table.

Dr. LLOYD ROBERTS, in reply, said that no ascites was present.

Dr. W. E. FOTHERGILL (Manchester) recorded a case of hyperpyrexia associated with thrombosis of the vena cava inferior. The patient was delivered by a midwife on March 21st, 1902. Fever set in and intensified until removal to hospital on the fifth day. Improvement followed intra-uterine douching at first, but a relapse occurred on the 31st, so the uterus was curetted, several pieces of placenta being removed.

On April 6th the temperature reached 111.2° , but was reduced to 107° by hot sponging. Thrombosis of the right femoral vein was quickly followed by involvement of the left, and from this time onwards till death on May 14th, there were no symptoms except increasing weakness, though the temperature continued high and remittent, with repeated rigors. There was no sign of suppuration or embolus in any other organ. The immediate cause of death was œdema of the lungs. Post-mortem examination: Uterus and other pelvic organs normal; no sign of general or pelvic peritonitis; inferior vena cava and its tributaries filled with ante-mortem clot from the heart downwards.

The PRESIDENT inquired how long the temperature remained at 111.2° , and whether there was any œdema of the lower extremities?

Dr. RABAGLIATI (Bradford) referred to cases in which temperatures of as much as 120° had been recorded, and held that mere elevation was not so important as variability of temperature. He suggested that the thrombosis might have been due to some general condition, e.g., hyperinosis of blood. The tendency at the present time was to lose sight of general principles.

Dr. GLYNN WHITTLE (Liverpool) asked if there was any spasm of the uterine muscle?

Dr. E. T. DAVIES (Liverpool) denounced the use of all curettes, and of sharp ones in particular, in puerperal conditions.

Dr. LLOYD ROBERTS (Manchester) considered the intra-uterine conditions responsible for all the trouble.

Dr. FOTHERGILL, in reply, said that œdema was absent, and the only symptom that might have indicated thrombosis was violent lumbar pain. The finger had been employed before the use of the curette, and no spasm was found. He was inclined to regard the curetting as the cause of the thrombosis.

Dr. J. B. HELLIER (Leeds) read a case of double pregnancy in a double uterus. The patient, æt. 34, had had three normal labours previously. During the fourth pregnancy the uterus was larger than usual. After a normal labour a female child was born, head first, its placenta following. The presence of a second child was discovered, but the medical attendant on introducing his hand found the uterus empty. Dr. Hellier found a second os lying high up, in front of and to the left of the other, and delivered a male child by podalic version. The uterus was bicornuate, a fairly thick septum dividing the two cavities, and there were two separate ora opening into a single vagina.

Dr. BRIGGS (Liverpool) had seen three cases of the kind, and he confirmed Dr. Hellier's account of the relative positions of the two ora. The condition should be thoroughly investigated under anaesthesia.

Dr. Lloyd Roberts also spoke, and Dr. HELLIER replied.

Dr. T. ARTHUR HELME (Manchester) read a short communication on dilatation of the cervix uteri in eclampsia of pregnancy by means of Bossi's dilator. Dr. Helme found that this dilator could effect full dilatation in twenty minutes, another ten being required for complete delivery with forceps. He had been surprised by the ease and comfort with which the instrument could be used without any laceration of the cervix, and thought this means afforded a marked contrast to manual dilatation with its frequently accompanying discomfort and cramp. He propounded two questions for consideration:—(1) The advisability of ending pregnancy when once convulsions have occurred; if the existence of pregnancy is a vital factor in the production of the eclamptic state, is not the termination of that pregnancy a vital factor in treatment? (2) The wisdom of administering large doses of morphia by the hypodermic method. The drug is given in acute and recent forms of nephritis, and withheld in more chronic forms; does not the same apply to eclampsia? In conclusion the author referred to the collective investigation just commenced by the Clinical Society of Manchester on the subject of eclampsia.

The PRESIDENT held that there was undoubted shock associated with eclampsia, and asked whether there was not much more shock when the cervix was dilated rapidly?

Dr. RUMBOLL (Leeds) had used Bossi's dilator in a case at the sixth month, and he preferred it to fingers and Barnes' bags. It was easily used and did not tear the cervix.

Drs. A. Stookes and Glynn Whittle (Liverpool) also spoke, and Dr. HELME replied.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 21st, 1903.

MORBUS BASIDOWII AFTER RIFLE FIRE.

The *Deutsch Militär-ärztl. Zeitsch.*, 10-1902, contains an account of the following rather curious case:—A recruit who had fired for the first time with blank cartridge was highly excited at the report and recoil of the explosion, and at once was attacked with palpitation, trembling in his limbs, insomnia, and giddiness. These troubles increased during the next few days, so that he had to be admitted into hospital. The recruit was of a family in which several cases of heart trouble had occurred, he had also himself suffered previously from palpitation, but was healthy when he joined the forces. On admission the man was found to be of average power, the thyroid was somewhat enlarged, cardiac dulness reached from the mid-sternal to the line of the left nipple and upwards to the upper border of the fourth rib. The first sound at the apex and base not clear, second sound at base accentuated. Pulse of moderate strength 88, pulse at work 154, irregular; moderate trembling of the hands. In the further course under rest in bed, ice bags, digitalis and strophanthus, the cardiac symptoms increased in intensity; pulse 160, sinking to below 100 at night; in the morning sometimes over 200; strong labouring of the cardiac region, the apex being pushed beyond the line of the left nipple in the 6th intercostal space. Cardiac sounds variable, sometimes clear, sometimes a systolic murmur at all openings. Often there was fleeting redness of the skin, but no capillary pulse. There were systolic murmurs over the large vessels. Later on, about six weeks after admission, a varying increase in the swelling of the thyroid took place, then exophthalmos of both sides, and Gräfes' symptom now developed. Besides these there were psychical symptoms, excitability, anxiety, sleeplessness, trembling of the hands, hypersensibility, exaggerated reflexes, excessive sweating and epistaxis. Twice rheumatic joint affections appeared with fever, otherwise the temperature was always normal. After about four months' treatment the man was discharged invalided, as no essential improvement took place.

As regarded etiology, a delicate constitution played a part. There were also hereditary tendencies and a mental shock, factors which, in combination, sufficed to overturn the mental balance.

At the Medical Society a discussion on

"FOOD" TUBERCULOSIS

was resumed from the meeting of the 11th inst.

Hr. Benda observed that he had pointed out the importance of predisposition in previous publications, thus accounting for perfect freedom of some parts of the intestinal tract from the disease. Further, all primary tuberculosis of the intestines must not be looked upon as "feeding" tuberculosis, and still less must all "feeding" tuberculosis have their origins in tuberculous cattle. The bacilli could enter in other ways than by the mouth, by breathing, kissing, some trade occupations such as glass blowing, etc.

The "Kasmistik" was not decisive one way or the other, either for or against Koch's views. Statistics

might be of value from countries where much raw meat and milk were consumed, which might show whether tuberculosis was more common there than elsewhere. But here came a difficulty, the conception of tuberculosis was not the same in all countries. In any case, infection from animals suffering from *Perlsucht* was practically of but little importance.

Hr. Cornel believed that he had shown in his earlier experiments that tubercle bacilli could pass through an injured mucous membrane, and defended the bacteriologists from the charge that they had undervalued the importance of disposition.

Hr. Ritta pointed out the great importance of the subject of the identity of the two diseases as regarded the feeding of infants, and recalled the endeavours to obtain the milk free from germs; not by subsequent boiling, as that would alter the chemical composition of the milk. He called to mind a country experience where a large number of infants were fed with the milk from a tuberculous cow, and not one of them took intestinal tuberculosis. He himself had only two cases of intestinal tuberculosis in his own practice, one a child of seven, and the other of eight. In younger children he had never seen it.

The *Deutsch Med. Zeit.* No. 14, 1903, contains an interesting case of

APPENDICITIS,

related by Prof. Roux. A young man, *æt.* 21, had an attack of appendicitis in December, 1901, was advised by his medical attendant to submit to an operation when the attack had subsided. When he got better, however, the advice was disregarded. On June 3rd he had worked all day, had gone to bed in perfect health, and had slept soundly until early morning, when he was awakened with great pain in the right iliac region, which compelled him to see a surgeon. At half-past nine in the morning, four and a half hours after the commencement of the new attack, he was admitted into hospital. Here, in the assumption that a newly beginning appendicitis would be found, an operation was begun. Behind the cæcum, with which a loop of small intestine was adherent, the appendix was met with. It was tense and full, kinked and perforated, and it formed, along with the iliac fossa and the cæcum, the walls of an abscess the size of half a nut, within which lay a fairly large faecal concretion. The case shows, as the writer says, that even when excision of the appendix is undertaken in a free interval surprise may be looked for. The abscess, the perforation, and the calculus were together present in such a way as to set up the threatening symptoms that led to the operation.

The case was shown to the meeting.

Austria

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 28th, 1903

MELANOTIC SARCOMA OF CHOROID.

AT the *Gesellschaft Sachs* showed a man with melanotic sarcoma on the lower internal quadrant of the eye. The diagnosis was made by means of Gartner and Reuss's lamp, which Sachs himself has much improved. The lamp is from sixteen to twenty-five candle-power, and is contained in a capsule of lead ten cm. in diameter. The light is conducted through a conical tube of glass six cm. in diameter, the end whereof tapers off to three millimetres in diameter. The small end is applied to the convex surface of the eye. When this point of concentrated light from the incandescent lamp is directed to the external surface of the sclera the internal cavity of the eyeball is entirely illuminated, so that the fundus and internal

surface thereof can be easily explored. The wall itself, from its thickness, will interfere with the transmission of light and thus allow the diagnosis of a tumour on the wall without difficulty. An elevation of the retina on the internal surface may often be observed without any tumour or may be due to a collection of fluid, but the non-penetration of light is diagnostic of its solidity.

ECTOPIA VESICÆ OF THE BLADDER.

Clairmont showed two patients who had been operated upon by different methods for ectopia of the bladder. The first case was a lad, *æt.* 17, on whom he had operated by Trendelenberg's method, *i.e.*, by an incision over the sacro-iliac synchondrosis, taking up the edges of the mucous membrane, and suturing them together, but the success was not what he had expected. A second plastic operation combined with direct suture of the flaps was likewise unsuccessful, although it has so improved the conditions that an anatomical cavity was formed leaving a fistula on the dorsum of the penis which functionally was practically non-existent. After two further attempts the fistula was closed by plastic operation and the penis so compressed against the margin of the pubic bone that the patient could retain his urine for an hour and a half by the simple device of pressure.

The urine secreted is cloudy, ammoniacal, and contains one per cent. of albumin.

The second case was that of a child, *æt.* 3½ years, with a similar malformation, but the operation selected was Maydl's, in which the ureters are transplanted to the rectum. The child is now well, and is able to contain its urine for five hours at a time. He therefore concludes that functionally the latter operation is preferable, and has moreover many advantages over the former. The plastic operation often interferes with the function of the kidneys, thereby producing calculi, with dangerous results; he therefore recommends Maydl's operation on the grounds of ease and safety.

CARCINOMA OF THE STOMACH.

Kristinus next brought forward a patient on whom he had operated for carcinoma of the stomach by Kocher's method. This may be described as a gastroduodenotomy, whereby the diseased tissues are removed from the stomach and the stump of the duodenum brought up and united to the remnant of the stomach. Eiselburg said that he had twice operated by Kocher's method, but he thought such an operation could only be justified under special circumstances, as he considered Billroth's method to be much superior.

TOTAL PROSTATECTOMY.

Zuckerkindl showed a man, *æt.* 75, who had suffered for many years from chronic incomplete retention of urine due to hypertrophy of the prostate gland. The conditions having become serious to health, he resolved to remove the gland by opening the perinæum and enucleating it in its entirety. The success was perfect, for within three weeks the patient was able to expel every drop of the residual urine.

Frisch agreed that total prostatectomy by the perinæum was superior to all other methods, and more particularly to Bottini's method, which he thought impracticable, though he admitted that French surgeons contested this superiority. As a proof of its success he mentioned that at the Urological Congress held in Paris last year eighty-two cases were recorded, of which Albarn himself performed forty-two with only one death. It may be remarked that a gland weighing less than from ten to fifteen grammes could hardly be said to be hypertrophied and did not necessarily call for operation. In connection with this operation it must not be forgotten that Reynes, of Marseilles, has three times met with psychical disturbances after total prostatectomy.

Zuckerkindl said that he thought the indications for this operation were complete retention of the urine, difficulty in introducing a catheter, and other complications asso-

ciated with hypertrophy of the prostate such as stone hæmorrhage, &c. All other cases, he thought, might be treated more successfully by palliative measures.

The Operating Theatres.

GREAT NORTHERN HOSPITAL.

OPERATION FOR FEMORAL HERNIA.—NEW METHOD OF DRESSING THE WOUND.—Mr. PEYTON BEALE operated on a man, æt. about 35, who had been admitted with a femoral hernia which had lately become irreducible. The hernia had been present, but easily reducible, for about three years. The operation was undertaken as the patient was seeking promotion in the postal service. An incision was made as far outwards as possible; the sac when exposed was seen to be very thick; when it was opened it was found to contain large intestine with very numerous and large appendices epiploicæ, one of which was adherent to the sac; this was divided between ligatures, and the intestine returned without difficulty. The sac was then stitched down to the fascia around the saphenous opening, having been first drawn together with a purse-string suture. The wound was closed in the ordinary way, and a film dressing applied as follows: the skin all round the wound for one inch in every direction was swabbed with acetone in order to remove all moisture, then a piece of velvrl film large enough to overlap the wound by about an inch was cut ready for application; this had been previously sterilised by immersion in boiling water; the wound and the skin round it were then painted with a velvrl solution, *i.e.*, velvrl dissolved in acetone; the piece of film was next placed upon it, and was covered with a large pad of sterile wool, over which a bandage was firmly applied. Mr. Beale said that he had been using this method of dressing wounds of all kinds for about a year and a half; the velvrl film was a cellulose preparation, elastic, transparent, very tough, and practically insoluble in everything but acetone; it could be sterilised either by immersion in boiling water or by the use of antiseptics, and when applied to a wound in the manner described formed an absolutely gas and water-proof dressing. The film was about the thickness of writing paper; he had used it, he remarked, even in wounds which were still oozing, for, even if a little blood did escape beneath it, it was easy to apply sufficient pressure by means of wool and a bandage to check it; even under such circumstances, the film was found to adhere quite firmly, and to prevent the entrance of air into the wound. He had also used it in wounds which were suppurating, and had observed that under these circumstances the pus became absorbed without giving rise to any constitutional disturbance. He pointed out that making use of this dressing in aseptic wounds, it was of course, essential that the usual precautions taken to cleanse the skin prior to operation should not be in any way relaxed. He had had two cases in which suppuration occurred under the dressing, these were both strangulated herniæ in which, as was well known, the fluid in the sac is highly septic, but the suppuration was modified and was of a much milder form than that which occurs in such cases beneath an ordinary gauze dressing, nor was there any elevation of temperature as is usually seen. In an ordinary aseptic case, he said, when the film is moistened and stripped off on the fifth day, the wound is found perfectly healed; when the stitches are removed each stitch hole should be painted over with a drop of the solution.

ST. PETER'S HOSPITAL.

EXTIRPATION OF KIDNEY FOLLOWING NEPHRO-LITHOTOMY.—Mr. SWINFORD EDWARDS operated on a man, æt. about 40, on whom a month previously he had performed nephro-lithotomy on the right side. On that occasion the kidney was found to be small, containing in its pelvis

a somewhat soft and mixed stone; the calculus smashed up during extraction, and so the pelvis had to be flushed out; the wound in the cortex through which the stone had been extracted was carefully closed with deep-lying sutures. The kidney was replaced, and all bleeding having stopped a large drain was inserted down to the kidney, and the wound closed in the ordinary way. This operation was followed by considerable bleeding into the bladder, lasting three days, but this was arrested eventually by the internal administration of such remedies as adrenaline, ergotin, and hazeline. The next thing that had to be contended with was partial suppression, for which hot air baths were employed and digitalis used as a diuretic. The patient was naturally much prostrated by these complications, but in spite of this it was hoped he would now do well, but after the lapse of a day or two his temperature began to go up; every morning it was about 100°, and in the evening 101°, sometimes even higher, clearly pointing to some septicity. In addition to this the man began to suffer from a septic rash. Looking to the case as being one of possibly streptococcus infection, the patient was treated by injections of anti-streptococcic serum which at first seemed beneficial; they, however, soon lost their salutary effect, so Mr. Edwards concluded there was nothing for it but to remove the kidney. The patient having been anaesthetised, was placed on his side with a good-sized sand bag under the left loin. The old scar was excised and the kidney exposed after cutting through a considerable amount of dense fibrous tissue. The organ was not found to be inordinately bound down, and therefore its extirpation was attended with less difficulty than might have been anticipated. The ureter was first isolated and separately ligatured after Mr. Edwards had ascertained that it contained no calculous debris. On the removal of the kidney the organ was found to contain a purulent fluid and but a thin layer of cortical substance was left. The wound was next lightly packed with iodoform gauze, drained and closed by buried and superficial sutures. Mr. Edwards said that he could find no special cause for the hæmorrhage which succeeded the nephro-lithotomy; such a complication, he remarked gives rise to considerable anxiety, but although he had met with it on two previous occasions, the cases eventually did well without further operative interference. He pointed out that in the present case toxic symptoms had supervened owing to the pyelitic condition found at the time of the first operation; moreover, it had then been a matter of some difficulty to wash out the debris of the stone from the various calices. The failure of the treatment by antistreptococcic injections he thought was without doubt due to the fact that suppuration was going on in the kidney which the treatment was not capable of arresting.

A fortnight after the last operation the patient was much improved, and Mr. Edwards has every hope of the man's ultimate recovery.

A PRESCRIBING CHEMIST IN TROUBLE.

AT the last Lincolnshire Assizes a retail chemist of Spalding was convicted of manslaughter and sentenced to fourteen days imprisonment. It appeared that in making up a cough mixture for a farmer customer he dispensed the strong solution of ammonia, thus causing the man's death. When the bottle was brought back to him for an explanation he threw the contents away and added "in water" after the directions. In view of the collateral consequences to the accused the judge took a merciful view of the case, but declined to pass over the offence altogether.

THE COST OF THE SMALL-POX EPIDEMIC IN LONDON.

THE total cost of the recent epidemic of small-pox in the Metropolis up to date amounts to close upon half-a-million sterling.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 6d. Post free, 54d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25 Os. 0d.; Half Page 22 10s. 0d.; Quarter Page, 21 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books &c.—Seven lines or under (70 words), 4s. 6d. per insertion 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 4, 1903.

ALCOHOL AND INSANITY.

THE fact that a very large proportion of the persons who find their way into our lunatic asylums have been addicted to the abuse of alcoholic beverages is not of itself conclusive proof that alcoholism is an etiological factor of overweening importance in determining the loss of mental equilibrium. The more closely we study the personal and family history of the chronic inebriate the more apparent does it become that the habit is the consequence, rather than the cause, of the mental weakness, a view which has not been without influence in recent legislation. This displacement of the popular relationship of cause and effect is even more marked when the history of the alcoholic insane is inquired into. A very large proportion of the victims come of a neurotic stock, many of them live, so to speak, in an atmosphere of physiological misery, and life is more or less a burden to them; hence the willingness with which they fly to alcohol. For a brief period the stimulating action of the alcohol restores the balance of the cerebral circulation, and remedies the cerebral anæmia which renders the conditions of life insupportable. The normal man, under the empire of a fit of despondency due to overwork, misfortune or unrequited love, may go and get drunk, but resumes command of himself so soon as the external depressing influence has been withdrawn. The abnormal individual lives his whole life under these depressing conditions, and the resumption of consciousness coincides with a return of his morbid unhappiness. No doubt indulgence in alcohol accentuates the pre-existing mental weakness and precipitates the ultimate decadence, but in the cases under consideration it is merely an accidental, and not an essential factor the which

is to be found in heredity and unfavourable social conditions. It is important that the precise bearing of alcoholic indulgence on the production of insanity should be determined, if only to emphasise the fact—for it may be justly so described—that inebriety is a disease and not merely a habit. The strain imposed on the nervous system by the conditions of civilised existence in large towns tends to the production of symptoms of depression consequent upon the exhaustion which, *en bloc*, are comprised under the term neurasthenia, and a craving for stimulants is one of the most constant manifestations of the victims of nervous exhaustion. Much the same condition of things may be brought about by the extreme monotony, the mind becoming atrophied, so to speak, a state of things by no means limited to those who dwell in the country far from any source of amusement or intellectual occupation. Excessive mental stimulation and inadequate mental excitement both tend to bring about a condition favourable to habitual recourse to intoxicants. The special point to which we desire to direct attention is that alcoholism but rarely determines insanity in the absence of a neurotic predisposition. The presence of a certain proportion of alcoholics among the insane might just as well be taken to show that people predisposed to insanity are specially addicted to intemperance. After all, only about thirty per cent. of the admissions are directly ascribed to this cause, and when we bear in mind the peculiar mental instability of the patients included in this percentage, one can hardly experience surprise at a habit which may fairly be classed as a symptom rather than a cause of mental breakdown.

THE ETIOLOGY AND TREATMENT OF ECLAMPSIA.

THE Clinical Society of Manchester have undertaken a troublesome task, for which, if they succeed in obtaining any practical result, they will well deserve the thanks of both the medical profession and the public. For a long time, eclampsia has been the opprobrium of the medical practitioner. Its pathology is unknown, its treatment is unsatisfactory, and its prognosis both for mother and infant is bad. We therefore learn with great pleasure that the Clinical Society have undertaken to institute a collective investigation of this disease, and that with this object in view they are sending out circulars to practitioners in the British Isles to invite them to report cases which occur in their practice, especially noting the treatment adopted and its results. A form has been drawn up with the object of guiding the practitioner as to the important facts which the society require, and these forms will be sent to any medical man who applies to Dr. J. Price Williams, Swinton, near Manchester, who is the honorary secretary. The Clinical Society of Manchester deserve the support of the members of the profession in the arduous task they have undertaken, but we fear that there are many inherent difficulties which will obstruct the due discharge of it. The diagnosis of eclampsia is a matter of some difficulty, the making of

which often tests to the full the skill of a specialist. It will be extremely difficult to exclude from the cases reported to the Society cases of epilepsy, true uræmic convulsions, hysteria, and delirium tremens. Further, the difficulty of establishing a definite fixed line of treatment will be very great. Eclampsia is essentially a disease due to neglect or failure of the eliminatory functions of the body, and any treatment other than prophylactic will always be unsatisfactory. When a patient suffering from albuminuria has been on milk diet for a week, says Tarnier, she to a certainty escapes eclampsia. Eclampsia, says another French author (Ribemont-Dessaignes), occurs almost exclusively in women whose urine has not been examined during pregnancy. When eclampsia does occur it is the symptom of a failure of the eliminatory functions of the body to a degree which probably varies with the nerve excitability of the patient. In other words, it is probable that a woman who is easily thrown off her nerve equilibrium will develop eclamptic convulsions at an earlier period in the course of a progressive intoxication than will a woman whose nervous equilibrium is more stable. All this makes the treatment more complex, and renders it almost impossible to determine, or even to hope to determine, any one line of treatment which will give satisfactory results in every case. If the eliminatory functions of the body are destroyed, even temporarily, it is obvious that the possibility of restoring them within a certain time depends upon the condition of the patient, and that in many cases the latter must come under treatment after all hope of their restoration is gone. We do not wish in any way to discourage the Society or to decry the importance of their task, but only desire to call attention to the impossibility of establishing any one line of treatment as *the* line of treatment. Previous results have already shown the impossibility of this, for in no disease so much as in eclampsia is the treatment adopted by one school so truly the treatment condemned by the other. Morphia and chloroform have their strong supporters and equally strong condemners. The induction of labour affords the only hope according to some, and is certain death according to others. The truth is, that the most successful obstetrician so far as eclampsia is concerned is he who avoids a rigid line of treatment and adopts such measures as seem to be most suitable to each particular case. General principles may govern our treatment, but rigid rules ought not to be allowed to do so. Check the convulsions, restore the eliminatory functions, and empty the uterus as soon as possible are the guiding principles, and in each case the manner of carrying them into effect will probably differ. The proposed inquiry of the Clinical Society may help to determine what methods of carrying them out are best under certain circumstances, and, if it does this, it will have accomplished an important task. The Society cannot hope to establish a universal treatment.

THE MYSTERY OF SLEEP.

SLEEP, although an integral factor in our mun-

dane existence, still remains wrapt in the mystery of the unknown. We know but little regarding its physiology, and less as to its pathology. Every physician accepts it as affording the most important of agencies making for recreation, physical recuperation, and mental restoration. Loss and derangement of sleep stand foremost among conditions threatening individual welfare. It is an essential to life, or, rather, it is the most important of the alleviating phases of personality. Its serious study has been much neglected, and even still the greater part of the literature concerned with the state of sleep is little better than an unregenerated and disordered collection of curious and often altogether unreliable impressions which, while highly interesting to speculative minds, afford but little that can be considered of practical service. Among recent contributions worthy of careful study mention must be made of the serious and very valuable essay appearing in that fascinating work of the late Professor Frederic W. H. Myers, recently issued "Human Personality." In it the author shows that no satisfactory physiological definition of sleep has yet been attained; and, indeed, such is being rendered increasingly difficult by what we now know of hypnotic sleep, which would seem to be induced in apparent independence of the supposed physiological requisites of slumber. It is necessary to view sleep in its positive characteristics, and regarded as a secondary personality in which the abeyance of the supraliminal life may be the liberation of the subliminal. Sleep, although it habitually suspends conscious powers, yet undoubtedly sometimes enhances the power of visualisation, and may even increase muscular control, as is seen, for instance, in somnambulism. Every medical man must have met with patients who complain of the prolongation of dream images into waking life—hypnopic pictures, as Mr. Myers terms them—and not a few persons are conscious that there is a heightening of the power of visualisation in *illusions hypnagogiques*, when the inward vision is on the verge of sleep. It is well known that Robert Louis Stevenson utilised such impressions to secure visual and dramatic interest for imagined scenes. All interested in the morbid manifestations of sleep should consult the remarkable series of examples collected and analysed in "Human Personality." The subject, viewed either from the physiological, psychological or medical standpoint is one of exceptional attractiveness, and we trust medical men, who, above most, have exceptional opportunities for investigating this subject, will take their part in the unravelling of the intricacies of the tangle which at present renders the land of sleep a terra incognita.

UNDER the will of Mr. Mellin (the originator of Mellin's Food) King Edward's Hospital Fund receives the munificent benefaction of £50,000.

DR. EDWARD MALINS, of Birmingham, has been elected President of the Obstetrical Society of London for the year ensuing

Notes on Current Topics.

General Medical Council.

A MEETING of the Executive Committee of the General Medical Council was held on Monday of last week, at which sundry matters of current interest were considered. The proof sheets of the Register were laid on the table, and a vote of thanks was accorded the Registrar for his efforts to accelerate the publication thereof. The request of the Medical Defence Union that the fine imposed on an unqualified practitioner whom they had successfully prosecuted should be returned to them in aid of the expenses incurred therein was acceded to. A communication from the Matrons' Council of Great Britain and Ireland, calling the attention of the Council to the assumption of the title of nurse by undesirable persons, with the object of enlisting the support of the Council in preventing this abuse, elicited the reply that the matter was not one that came within the statutory duties of the Council. The question of the performance of the ritual operation of circumcision by unskilled persons was brought up by two communications addressed to the Council, but it is obvious that the Council has no jurisdiction over such unskilled persons, and although it would view unfavourably any "covering" relationship between such unskilled person and a registered practitioner no objection could be taken to the attendance of a practitioner on a patient who had been unskilfully treated, "but his action must be entirely dissociated from that of the unqualified practitioner." The most remarkable question submitted to the Committee was that raised in a communication from the honorary secretary of the Liverpool Throat Hospital, from which we gather that a firm of chemists manufacture a pastille from the formula of the hospital, and have contracted with the Attorney-General to pay a yearly sum to the institution so long as they continue sole manufacturers thereof. The hospital staff do not object to the payment of the annual sum, but they resent the bond of secrecy which the Attorney-General is seeking to put upon them. The Committee replied that it was "extremely undesirable for professional men to pledge themselves to secrecy in regard to the composition of any remedy which they may use or authorise in the treatment of patients." A request for an "authoritative ruling" in respect of the desirability of requiring payment for school board certificates was met with a firm *non possumus*. The Committee discussed the revision of the Standing Orders in respect of the prevention of personation. The last item was a vote of condolence to the widow of the late Mr. Miller, who so long discharged the responsible duties of Registrar to the Council.

Dr. Freyberger and the Post-Mortem by Deputy.

IN our last issue we dealt briefly with the ungracious campaign against the medical profession in which Mr. Troutbeck, the coroner for the South-Western district of London, has embarked. That

gentleman, it will be remembered, requested the so-called pathologist of the London County Council to perform a post-mortem examination on the body of an infant instead of following the course usual to other coroners, and entrusting that duty to the medical practitioner who had attended the deceased. On that occasion Dr. Freyberger's hands were in such a condition that he was unable to touch the body, and the pathologist of the L.C.C. thereupon delegated his high powers for the time being to a humble mortuary porter. At the inquest, however, the indignant medical attendant made some remarkable statements. One allegation is so startling that we hesitate to accept its remote possibility, although it is quoted *verbatim* by a contemporary on the strength of a report published in a South London newspaper. It is stated therein that Dr. Kinahan asserted the infant had a fractured spine, which was overlooked by Dr. Freyberger because he never touched the body. Dr. Freyberger is credited with the remark that absolutely nothing escaped his notice at the post-mortem in question. If Dr. Kinahan's view be correct the pathologist will be now obliged to add the qualification "nothing—except a fracture of the vertebral column." We shall be curious to know what Mr. Troutbeck and the London County Council have to say in defence of a system that ousts the general practitioner in favour of a pathologist who forthwith appoints a porter as his deputy.

The "Infantile" Type of Muscular Dystrophy.

ONE of the most interesting points brought out in the discussion on the varieties of idiopathic muscular atrophy, as illustrated by a large number of cases shown last Thursday at the meeting of the Neurological Society, was the necessity of recognising a special "infantile" or "congenital" type. Dr. F. E. Batten exhibited several cases belonging to this class. They present a fairly characteristic aspect, and usually have such a history as clearly demarcates them from the other more or less definitely defined varieties of this mysterious affection. In the "infantile" form the patients are young, and manifest atrophy from a very early period, and it is generally found that they have never been able to stand or walk. Sometimes, in order to progress, they will lie on the floor and roll round and round on the long axis of the body, or hobble along with knees flexed on thighs in a sitting attitude, using the hands to assist. The feet and hands are often abnormally long, and flat and frog-like. The limbs may be almost flail-like, and movements at the joints are sometimes restricted. Although the facial expression may be expressionless, and the eyes in certain cases are peculiarly prominent, all facial movements can usually be performed. There does not usually seem to be any conspicuous mental deficiency. Sensation and muscular sense is not lost, but the knee-jerks are usually absent. The bones are all generally small, but there is usually an absence of spinal curvature. The

number of cases hitherto described as belonging to this type are at present small, and we have much yet to learn regarding their distinctive characters, but such particulars as are available certainly seem to warrant the recognition of a special "infantile" group. But little new light is forthcoming regarding the essential nature of the so-called myopathic atrophies, but the best neurological opinion seems set in the direction of a spinal origin, and it may be with improved methods of investigation of the cord by more elaborate pathological technique, minute changes may be detected sufficient to explain the curious selection and peculiar distribution of muscular atrophy met with in the various and, unfortunately, still somewhat ill-defined groups of myopathic dystrophy.

Ethics and Dyspepsia.

AN old proverb declares that "the liver is the seat of the Devil," and certainly gastro-intestinal affections and derangements of the digestive apparatus are generally credited with being instrumental in bringing disorder into the mental realm, and oftentimes exciting moral distemper. This point of view has been powerfully expressed by De Quincey: "The whole process and elaborate machinery of digestion are felt to be mean and humiliating when viewed in relation to our mere animal economy. But they rise into dignity, and assert their own supreme importance, when they are studied from another station, *viz.*, in relation to the intellect and temper. No man dares, then, to despise them. It is then seen that these functions of the human system form the essential basis upon which the strength and health of our higher nature repose, and that upon these functions chiefly the genial happiness of life is dependent. All the rules of prudence, or gifts of experience that life can accumulate, will never do as much for human comfort and welfare as would be done by a stricter attention and a wiser science directed to the digestive system." It is much to be feared that practitioners are too wont to lose sight of the higher influences of dietetics, and yet, as Professor Pawlow has clearly shown, the psychical factor in the formation of appetite is of the greatest importance, while general experience has amply testified to the close relation of ethics and dyspepsia.

Habit Formation in the Education of Children.

THE majority of mankind are wont to leave the conduct of their lives to the guidance of habits. A little reflection upon that proposition will soon convince the average citizen that habit controls and directs three-quarters of his actions at bed, at board, at home, abroad, in a word, it is the mainspring of his daily life, and serves much the same purpose as the faculty we call instinct in the lower animals. It has an equally strong influence upon his intellectual and moral decisions, so much so that many ethical and other complex considerations are settled off-hand by the application of

rule of thumb methods of thought. Many of these habits, both of mind and body, are doubtless formed as the result of many years of innumerable repetitions of the acts and thoughts most commonly originated by the special nature of the individual environment. A great proportion, no doubt, have their origin in the receptive stage of childhood. Perhaps one of the most striking instances of the direct value of habit formation in infancy is to be found in the gradually-acquired control of the sphincters. In the case of the bladder, where incontinence of urine persists beyond the second year, it rapidly acquires the nature of a great individual disability to its victim. The resulting drawback rapidly multiplies with the progress of the child into school and adult life. Yet in the younger days it is simply astonishing how much may be effected in the way of winning the little sufferer back into the control of a better habit formation. A similar process may be applied to many of the less readily recognised moral and intellectual defects, if only the guardians of the child have the wisdom to observe, and the necessary patience and kindness to correct and guide the child aright.

The Sale of Poisons.

THE recently-published recommendations by the Departmental Committee appointed to consider Schedule A of the Pharmacy Act, 1868, have both a direct and indirect bearing on all classes of the community. Many deaths, accidental and otherwise, are due to the fatal facility with which poisons can be obtained and criminally or carelessly handled. The Committee, by a majority of members, recommend an extension of the facilities for the sale of poisons used in agriculture and horticulture. There is undoubtedly a great field of usefulness in both the pursuits mentioned, as in the killing of weeds, the purification of seed, and the cleansing of sheep. The recommendation, however, if carried out, will involve the absurdity that a farmer can buy a large parcel of arsenic, say, a couple of stones weight, from a dry-stores dealer, whereas he would have to go to a licensed chemist for a medicinal dose of one-fortieth or one-twentieth of a grain of the same drug. Our own impression is that the scientific chemist could find non-poisonous substitutes for the operations of the farmer and the gardener. As at present administered, the law is most unequal. In consequence of a number of successful prosecutions by the Pharmaceutical Society in many districts poisonous sheep-dips and other applications can be bought only of licensed chemists, while in neighbouring districts they can be sold freely by any unlicensed dealer. In some Highland districts we are told that a farmer would have to go fifty miles to find a licensed chemist. The committee propose the addition of a number of poisons to the schedule. It is to be hoped that the labelling of patent medicines containing poison will be more stringently regulated, as well as the constant compounding of prescriptions containing poisons that have been long given to patients.

The Danger of Inflammable Combs.

THE use of gun cotton in medicine is mainly confined to its utilisation as a product of collodion. In the arts it has a far wider range of application, and just now it threatens to become of such universal application that its indiscriminate adoption must demand the attention of persons interested in preventive medicine. It has long been known that dressing combs and other articles of like nature have been manufactured from a modification of gun cotton. From time to time we have pointed out the possibility of accident from the use of articles containing such an ingredient, but comparatively few cases of accident have hitherto been recorded. Now it appears that the original patent having expired, a vast number of imitation processes have sprung up and the public are flooded with combs made from gun cotton compounds by methods which render them much more dangerous than those prepared under the original patent. That some restriction should be placed on its indiscriminate use was proved by the recent case of a girl, 22 years of age, who was suffering from cellulitis of the scalp, accompanied by a marked degree of nervous shock. It appeared that her head had been set on fire by the sudden combustion of a comb which she wore in her hair. Cooking her father's dinner one Sunday she happened to bend down before the fire, when the comb suddenly ignited and she became enveloped in flames. Her life was only spared through the presence of mind of her father, who immediately enveloped her with the hearth rug, and so extinguished the conflagration. Obviously, seeing that the mere storage of gun cotton is restricted by heavy penalties, it is not fair or safe that makers should be permitted to place a slightly modified but actively dangerous modification on the market, to be used by a section of the public who have not the slightest notion of its composition and dangers.

A New Anti-Staphylococcic Serum.

THERE seems to be a prospect that the number of "anti" serums will be shortly increased by a new and most curious one which is intended to combat staphylococcic infection. The comparative immunity to septic infection possessed by epileptics has led an Italian observer—V. Tirelli—to endeavour to determine experimentally whether or no this immunity is due to an anti-pyogenic property inherent in the blood. Accordingly, he treated cultures of staphylococcus with serum obtained from the blood of an epileptic patient, and then placed them in an incubator, with the result that the cultures were slower in developing than were control cultures which had been treated with healthy serum. Again, he injected cultures treated with the epileptic serum into the veins of animals, and these survived longer than similar animals injected with control cultures. An attempt was made to determine whether successive injections of epileptic serum would render an animal immune to staphylococcus infection, but this unfortunately

failed, owing to the accidental death of the animal which had been injected. A final interesting experiment consisted in injecting serum extracted from the body of the last animal into an animal in whom acute staphylococcic infection had been produced, with the result that the latter lived twice as long as a control animal in whom a similar infection had been produced. We hope that Signor Tirelli will continue his experiments, as they exhibit the pathogeny of epilepsy in a new light and may eventually afford a means of cure, not to mention the prospect they hold out of a trustworthy anti-staphylococcic serum.

The Treatment of Hospital Patients.

WE learn from a contemporary that a somewhat remarkable Bill has been introduced into the Assembly of the State of New York. It is apparently drawn up with the object of insinuating that female patients are not safe in hospitals, as it states in its preamble that it is "for the protection of the honour and morality of such patients." The first section declares it to be unlawful for any student, attendant, house physician, or anyone else, to expose the body of any female patient other than for operation. The second section makes the presence of at least three near relatives, guardians, or next friends at any operation permissible during the entire operation. Twenty-four hours' notice must be given to these parties, save in the case of an accident, and if for such a reason the notification is dispensed with "no person or persons other than immediate friends or guardians, or the next friend of such female patient, shall be permitted to witness such operation or any part thereof." This clause would appear to exclude the operator and nurses. The third clause contains the penalties for infringement of the first two. The offender shall "be deemed guilty of a felony, the punishment thereof shall be by a fine of not less than one hundred dollars, or by confinement in a county jail or State prison for a term of not less than one year and not more than five years, or by both such fine and imprisonment." This Bill is worthy of a country whose cranks are fertile in the production of such curiosities, and deserves to take equal rank with the famous anti-kissing Bill of another State.

The Liability to Fatal Chloroform Narcosis.

IT is generally believed, not only by the public but probably also by many medical men, that the risk of fatal chloroform narcosis is greatly enhanced by a feeble action of the heart. According to Dr. Hewitt, this view is far from correct. The strength of the heart muscle is, he assumes, more or less proportional to the muscular system as a whole, and this being so, the greater the muscular strength the greater the rigidity during the stage preceding muscular resolution and the greater the embarrassment of respiration. It follows, according to Dr. Hewitt, that a patient with what is known as a weak heart is in reality, a better subject for chloroform than a robust subject. Expert anæsthetists long since discarded the bogey of weak heart in this

connection, and it is a matter of daily experience that the very persons whose appearance is calculated to inspire apprehension in the minds of comparatively inexperienced anæsthetists take the drug admirably, while young robust subjects succumb in the most unexpected and disconcerting fashion. The moral to be drawn from Dr. Hewitt's *obiter dictum* is that the risk attending the administration of an anæsthetic is by no means directly dependent upon the physical condition of the subject. He might have added that the really dangerous subjects are the victims of chronic intoxication whether autogenetic as in Bright's disease or diabetes, or heterogenetic as in alcoholism or nicotine poisoning.

The Sanatoria for Tuberculosis Question.

THE decision to erect a palatial building to be called the King's Sanatorium for the reception of a hundred phthisical patients raises anew the question whether the construction of such a building is calculated to afford the maximum benefit from the funds available. In view of the immense number of persons throughout the country suffering from incipient consumption for whom no accommodation is at present available we hold very strongly that it would in general be far preferable to construct light wooden, or even canvas, dwellings which could be removed or renewed as occasion may require in preference to more solidly-built constructions with a limited number of beds. To be of any material service it will be necessary for every county to provide sanatoria for the consumptive inhabitants of the locality and this is obviously impossible if extravagant sums are required for building purposes. Permanent buildings for the reception of persons suffering from pulmonary consumption are in many respects undesirable, for they, and the site on which they are erected, must sooner or later become contaminated.

Preservatives in Potted Shrimps.

THE question whether the use of preservatives in the preparation of potted shrimps constituted an offence under the Food and Drugs Act has been most thoroughly considered by the stipendiary magistrate for Manchester, and he has now given his decision. It is impossible to refuse our admiration for the extremely judicial and thorough way in which the magistrate discussed the subject as a whole. He had before him the evidence of a number of eminent experts, most of whom took the view that the use of large quantities of boracic acid is prejudicial to health, but, as the magistrate pointed out, they were not unanimous in their conclusions, and were unable to support their contentions by reference to instances of actual injury due to this cause. The fact that boracic acid has been extensively used for this purpose for upwards of ten years without any complaint of injury to health thereby is certainly a point to be borne in mind, although in view of the imperfect knowledge which we at present possess in regard to the physiological effects of the acid, it might very well be that the symptoms, if any, could not be referred to their cause. Upon the balance of

testimony the magistrate formulated the conclusion that a preservative is requisite for the preparation of potted shrimps as an article of commerce in a fit state for carriage, and he consequently dismissed the case. We cannot dissent from the verdict so carefully thought out, but in view of the importance of the interests involved, it is to be hoped that steps will be taken to ascertain more exactly the precise effects of the habitual ingestion of aliments treated with the various preservatives in general use. Obviously their use in respect of such an article as potted shrimps is less open to objection than, for instance, in milk, of which large quantities are consumed, but while the public health must be protected, it is highly undesirable to interfere with important industries without conclusive evidence of actual injury.

The Report on Cremation.

THE report of the Departmental Committee appointed by the Home Secretary to inquire into the conditions under which the practice of cremation can be carried out with safety has just been issued. The committee are of opinion that while no regulations that can be devised can possibly offer an effectual barrier against the possible concealment of crime, the regulations which they suggest will probably make cremation at least as safe as the existing method of disposing of the dead. The regulations which are suggested really do little more than embody those actually in force by private initiative. An independent medical certificate of the cause of death is recommended in addition to that delivered by the medical attendant of the deceased, failing which the certificate of a skilled pathologist after a post-mortem examination, or, in default of the preceding, a coroner's certificate. The report comprises draft regulations for the maintenance and inspection of crematoria and sundry incidental details.

Disease and de Quincey.

It has always been a point of much interest with biographers to allocate the directing force or modifying influence of physical disease and mental derangement on the character and work of their subjects, but few serious attempts have been made to study with anything like scientific precision the various morbid conditions which have handicapped or damaged the life of the world's workers. And yet the subject is one of peculiar fascination and rich in material which may serve for practical application in the present. Dr. Gould has recently, in his attractive "Biographic Clinics," attempted to throw light into this dark recess of human affairs. In his very ingenious study of the symptoms which darkened the life of Thomas de Quincey, he seeks to show that the great writer owed much of his suffering, and perhaps a great deal of his opium habit, to myopic astigmatism of some anomalous and anisometropic variety. The evidence suggestive of such a view may not be altogether convincing to the ordinary non-ophthalmic mind, but certainly the ingenuity and skill manifested in marshalling facts in favour

of such an interpretation is considerable, and the data presented affords much material for serious debate. Unfortunately, in the past, as still in the present, not a few among distinguished labourers are peculiarly reticent in admitting the limiting influence of physical defects, and often foolishly reluctant to take reasonable steps to compensate for bodily deficiencies, or even seek rectification of such minor ailments as are common to all flesh. And such is particularly the case in regard to ocular impairment. Many a public man will continue for years to suffer much discomfort, and even curtailment of usefulness, rather than rectify his failing or abnormal sight by wearing spectacles. Perhaps the foolish custom of prohibiting glasses in the army has done something to maintain this utterly foolish attitude. But, maybe, behind it all is that element met with at all ages and in all classes, the personal pride which, according to the most voracious of witnesses is never hurt.

The State Registration of Nurses.

THE feeling which must have prompted Mr. Gant to write the drastic criticisms of the nursing sisterhood which appeared, in part, in our columns under the title of "Mock Nurses," seems to be shared by the nurses themselves, or some of them. We note that a movement has been set on foot by Miss Helen Todd, matron of the Brompton Hospital for Consumption, to secure Parliamentary sanction to a scheme for the State registration of trained nurses. It is very generally felt that the public are entitled to protection against women who usurp the title of nurses on feeble credentials or none at all, and whose character may not be such as would commend them for employment. We cannot, of course, express approval of a scheme with the details of which we are as yet unacquainted, but the principle is one which will probably command acceptance. As we mention elsewhere, an attempt to enlist the support of the General Medical Council to the movement has proved futile, not, we may surmise, from any lack of sympathy with the object in view, but simply because the matter is not within the scope of the Council's functions.

The Treatment of Ophthalmia in Egypt.

THE recent generous gift of £40,000, entrusted to Lord Cromer and his successors in office by Sir Ernest Cassel for the relief of ophthalmia and eye diseases, and for the training of qualified men for such work in Egypt, was the direct outcome of the Khedive expressing interest in the subject, as contained in the proposal for an ophthalmic research hospital, which had been submitted by Mr. Kenneth Scott, ophthalmic surgeon, of London, in the hope that the funds required for starting it might be provided. The officials of the Sanitary Department, Egyptian Government, into whose hands the expenditure of the sum has virtually passed, have decided to employ it in establishing a tent in the form of a "travelling dispensary," to suffice for all purposes of operation and treatment,

and to work solely in the provinces. They will appoint an additional English inspector for a temporary period to travel with it, accompanied by a native Egyptian doctor, a post-graduate local medical student, two male hospital attendants, and two servants. Beyond the initial cost of about £250, its maintenance, inclusive of salaries, is estimated at £900 per annum.

Post-Graduate Instruction for Nurses.

IN many instances the period of training for nurses is all too short, and the opportunities for acquiring not only the art of attending the sick, but securing such technical knowledge as shall enable an intelligent woman to carry out the instructions of the medical practitioner are meagre and sadly inadequate. It must be remembered that rapid progress is being made in the elaboration of detail in many forms of nursing. Special methods of treatment, such, for instance, as sanatoria treatment of the consumptive, and new procedures in surgical and gynecological practice, and fresh developments in many of "the specialties" make it essential that a nurse should continue her training through life and not consider herself "finished" when turned out of her training school. The proposal to institute Post-Graduate teaching, as it is somewhat incorrectly styled, for the certificated nurse is therefore one to be commended, especially in the case of "private" nurses. Every movement having for its object to raise the status of the nurse and improve her professional efficiency cannot but meet with genuine approval.

The Professorship of Surgery in the Catholic University.

THE governing body of the School of Medicine have appointed Mr. J. S. M'Ardle, F.R.C.S.I., Professor of Surgery in the school in succession to Mr. P. J. Hayes, who has recently resigned the post. Mr. M'Ardle has been assistant to the Professor of Surgery in the school for some years, and also holds the post of Visiting Surgeon to St. Vincent's Hospital. He has made numerous contributions to medical literature, and is well known as a skilful operator. Mr. A. J. Blayney, F.R.C.S.I., Assistant-Surgeon to the Mater Misericordiae, has been appointed assistant to the Professor of Surgery in succession to Mr. M'Ardle. We are glad to learn that the governing body of the school have fitly recognised the long services of the retiring professor—Mr. P. J. Hayes, F.R.C.S.E., by appointing him to the honorary post of Emeritus Professor of Surgery.

DR. Q. B. DE FREITAS, who for some time past has been acting as an Assistant Surgeon of the Colonial Hospital, Georgetown, British Guiana, has been appointed a Government Medical Officer of that Colony.

DR. H. MEREDITH HARRISON, Principal Medical Officer of British North Borneo, has resigned his appointment in the Government Service, and is entering the service of the Sultan of Johore.

The Hygiene of the Alien.

MUCH discussion is now taking place regarding many of the features considered undesirable by the average Englishman in the foreigners' mode and manner of life and methods of conduct. To the sanitarian, however, the most conspicuous drawback, in the alien is his deep-rooted objection to adopt the most elementary of hygienic precautions, and his utter neglect of agencies for maintaining such a measure of cleanliness as shall prevent his becoming a nuisance, and at times, an actual danger to washing members of the community. We are, therefore, particularly rejoiced to see that the sanitary committee of the Jewish Board of Guardians have issued directions printed in English, German, and Yiddish to the East-end aliens in which considerable stress is laid on the importance of cleanliness for the person, the clothing, and the home, and the need for fresh air in securing health. In case of need it is recommended that communication should be made with the sanitary inspector of the Board, or with the Medical Officer of Health for the Borough of Stepney.

Research and Accuracy in Quotation.

EVERY medical man engaged in research work must have experienced the trouble and irritation which comes from error and laxity in quotation. It is remarkable how slipshod many earnest workers are in their presentation of references and use of quotations. Inaccuracy and incompleteness in these respects should be grouped as among the cardinal sins. To all such sinners either through omission or commission we recommend a consideration of the advice given in the current number of *Notes and Queries*:—"Be accurate. Even a comma may seriously modify the meaning of a phrase. Quote as fully as necessary to preserve the meaning of your author. Do not take out just sufficient for your purpose if by so doing you misrepresent what is meant by the writer. Take care—while being accurate and quoting as fully as necessary—to see that the sense in which the words were written is not mistaken. They might have been ironical or otherwise. Always give chapter and verse." Such advice is excellent and we could wish contributors to medical literature would seek to follow it. The recent issue of the first volumes of the new *International Catalogue of Scientific Literature* and the resurrection of *The Index Medicus* clearly indicate the world-wide necessity for accuracy and completeness in the cataloguing of the rapidly accumulating bibliographical material connected with medicine and the allied sciences.

SIR HENRY BURDETT will give an address at the annual meeting of the Mount Vernon Hospital at the Central Offices in Fitzroy Square, on Wednesday, March 4th, at 4 o'clock.

DR. JUDSON S. BURY has been appointed clinical lecturer on neurology in The Owens College, Manchester.

Pulmonary Tuberculosis in Syphilitic Subjects.

SYPHILITIC phthisis has long been recognised as a condition often very closely resembling in its clinical manifestations, course and general pathological characters, not a few forms of pulmonary tuberculosis. But it has not been so clearly recognised that syphilitic subjects were peculiarly prone to tuberculous infection of the lungs. Dr. Douty, of Davos, has recently expressed an opinion, based on five years' observation of patients in that well-known Alpine resort of the consumptive, that 30 per cent. of the males who have phthisis are syphilitic. Many directors of Continental sanatoria and hospitals for the tuberculous put the proportion of syphilitics among the phthisical men at from 30 to 50 per cent. At the Charité at Berlin fully half of the male consumptives are said to be syphilitic. The question is one needing thorough investigation. Certainly in this country not an inconsiderable number of phthisical cases, both men and women, present evidences of having suffered from syphilitic infection, but this of course, may be said of all classes of cases and much careful research will be necessary before it can be conclusively said that syphilis is more frequent in consumptives than in patients suffering with other chronic diseases. Dr. Douty is much impressed with the benefit which syphilitics receive, especially in the early stages of the affection, from "open-air" treatment. We imagine, however, that it will be long before public sympathy with "syphilitic sinners" rises to the elevation allowing of the establishment of sanatoria for such, at least in many cases, undesirable members of the State.

"The Academy" and the Treatment of Diphtheria.

MEDICAL matters seem to exert an irresistible fascination for many literary laymen, but when such seek to expound the methods of the healing art we might at least hope that they would endeavour to obtain some near approach to accuracy. There is surely sufficient ignorance and superstition without seriously encouraging error, and we are astonished to find *The Academy and Literature* admitting such a misleading essay as appears in its current number, where the preparation and use of diphtheria antitoxin is thus explained: "Cultivate from some unfortunate child's throat a colony of the bacilli of diphtheria. . . . These inject through a hollow needle under the horse's skin. . . . Open a vein, one of those beautiful sinuous veins on the horse's leg, remove a few drops of blood containing the antitoxin, inject them under the skin of, say, the wrist of the choking child. In a few hours it draws the grateful breath of convalescence. . . . The death-rate has fallen twenty, fifty, sometimes ninety-five per cent. . . . The doctor need not calculate the dose in proportion to the age, or rather the weight of the child. He is dosing the bacilli, not the patient. So he gives the same dose to every case." This might be permissible in the works of some lady

novelist, but appearing in a serious review, and under the title of "science," it is, to say the least, discouraging.

Mr. Mayo Robson has been elected an Honorary Fellow of the American Surgical Society.

The annual conversazione of the West London Hospital Post-Graduate College will be held at the Hospital on Wednesday, March 18th.

Professor J. W. Byers has been appointed to the staff of the Belfast Maternity Hospital to fill the vacancy caused by the resignation of Dr. Brice Smyth.

Mr. A. Pearce Gould will preside at the 130th Anniversary Dinner of the Medical Society of London which is to take place on March 7th at the Whitehall Rooms, Hotel Metropole.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

DR. GRANT AND THE BALLACHULISH DISPUTE.—This dispute has already assumed somewhat serious dimensions, as many of the former workers in the quarries have gone to other districts to work, and a large number are now employed on the railway. A good deal of correspondence has recently appeared in the newspapers on the subject, and the opinion held generally is that Dr. Grant has been badly treated by the manager and directors of the company over which Colonel Malcolm presides as chairman. It is said that Mr. Shaw, M.P., holds a considerable number of shares in the company, and the explanation which he thought fit to make at a meeting a short time ago has not been considered satisfactory, as the correspondence in the newspapers has shown. The following extract from a letter which appeared over the signature "Labour" the other day may be taken as a fair specimen of what has been written on the subject:—"Slavery, whether in South Africa or the Highlands, is highly objectionable, and it seems to many that to deny to a body of men the right to select their own medical man; to refuse to pay them their hard-earned money until six weeks have elapsed, and then to turn them out when they complain of these legitimate grievances is the very essence of slavery." With only a very few exceptions Dr. Grant has the entire sympathy of the people resident in the district where he lives, and seems to stand high in the estimation of those requiring his professional services. He is entitled to the support and sympathy of the medical profession in the trying and painful position in which he has been placed for a considerable time by the apparently most oppressive action of the manager and directors of the Ballachulish Quarries.

NATIONAL SYSTEM OF RE-VACCINATION.—Recently Councillor Steele submitted the following motion on the above subject which had been standing before the Glasgow Town Council for some considerable time in his name. The terms of the motion are:—"That, in view of the experience obtained during the late prevalence of small-pox in Glasgow of the complete protection against the disease which recent successful re-vaccination affords to adults, and of the insignificant number of cases occurring in persons who had been re-vaccinated in former years, the Corporation desires to record its conviction that a national system of re-vaccination, on the lines on which infantile vaccination at present proceeds, would render recurring, widespread, epidemic prevalence of the disease impossible, and resolves that a copy of this resolution be forwarded to the President of the Local Government Board." Councillor Steele gave statistical information to prove the necessity for his motion. Councillor

Dick, the late Convener of the Health Committee, seconded the motion, which was unanimously approved by the Council. Such commendable action on the part of the Corporation indicates the advanced, enlightened, and progressive position to which it has attained on a subject of the most vital moment to every citizen, old or young, of a very large and ever-growing city.

HONORARY DEGREES, GLASGOW UNIVERSITY.—Among others, the following members of the medical profession are to have the degree of LL.D. conferred on them at the April graduation ceremony. Sir William Tennant Gardner, K.C.B., M.D., Emeritus Professor of the Practice of Medicine in the University of Glasgow, and now resident in Edinburgh, and Thomas Oliver, M.A., M.D., Professor of Physiology in the University of Durham, and author of a recent book respecting the diseases of dangerous trades.

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

DEATH OF DR. ALEXANDER.—A well-known and respected practitioner, Dr. Samuel Alexander, died at his home in Belfast on February 25th. He was born at Templepatrick, co. Antrim, and educated at Queen's College, Belfast, graduating in the Royal University in 1885. He settled in practice in Belfast, and received a dispensary appointment, which he continued to hold while he lived. He enjoyed as well a large middle-class practice in a populous neighbourhood of the city. Rather shy and retiring by nature, he seldom took part in public affairs, though a regular attendant at the meetings of the Ulster Medical Society, of which he was a Fellow. In January he had a severe attack of influenza, followed by pleurisy, which, in spite of surgical interference, eventually proved fatal.

BELFAST WATER SUPPLY.—An important pronouncement on the water supply and the progress of the Mourne water scheme was made at a meeting of the Water Commissioners on February 26th. It appears that the Woodburn system, which supplies the centre and the north side of the city and the neighbouring country gives about eight million gallons a day. The Stoneyford system, coming in from the south-west, brings three and a half million gallons. The latter supply came under public suspicion a year or two ago, when typhoid was exceedingly prevalent, and the commissioners have acted wisely in buying and enclosing several farms, from the surface of which much of this water comes. For the past year the Mourne system, still incomplete, has afforded a daily supply of three to eleven million gallons, but this will be greatly increased in a few weeks, when the Kilkeel River will be tapped at a point forty miles from Belfast, and brought into the system. The main part of the system, the great reservoir in the Silent Valley, in the heart of the Mourne Mountains, is making very slow progress, but not much light was shed on it at the meeting here referred to.

BELFAST WORKHOUSE.—One of the local papers is doing excellent service by publishing a series of articles on the workhouse and its administration. In the second article, published on the 28th ult., special attention was paid to the infirmary and the treatment of consumptives. At the date of writing there were 1,466 people under medical and surgical treatment in the infirmary, and over 200 of these are consumptives. The lack of space and air is apparent to the most casual visitor; how far, then, must it fall short of the ideal for the treatment of tuberculosis? Though the patients are as well fed and cared for as far as the circumstances permit, it is plain that there is but little chance of the arrest of the disease in such crowded surroundings, and for these poor people, generally young, nothing remains but patient waiting for the inevitable end. Certainly there is a fine opening for some of the merchant princes of this prosperous city to build and endow a sanatorium for the free treatment of suitable cases of tuberculosis. The medical men of Belfast will have no difficulty in filling it.

Correspondence.

THE SEMI-TEETOTAL PLEDGE ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—You were good enough to publish a few remarks from me in your issue of February 18th in reference to this promising association, which I for one have joined. I have since procured the official papers bearing thereon, and must confess that I was somewhat disconcerted on reading the startling paragraph at the back of the declaration, which I had not previously read, and which runs thus:—"Foundation Principle.—The movement is to be kept free from all anti-teetotal bias. *Total abstinence is always the best policy* (the italics are mine); abstinence between meals is a step in the right direction." Now, Sir, it is obvious the association has no substantial numerical authority, as I pointed out in my last letter, for making any such assertion, and it is presumptuous for it to do so. It is equally obvious that medical men can only be, and this by virtue of their vocation, judges on a point of this kind, not only as regards the utility of alcohol as a medicine, but, moreover, as to its necessity or otherwise as a factor in the general régime of diet. It is still further obvious that the association is not called upon to express any lay opinion on total abstinence; indeed, they go out of their way by so doing, and as only a very small section of our profession believe in it, it would seem a thousand pities to nip the bud in its infant or early stage of germination, which the association will certainly do if they indulge in any reckless or frivolous statements such as I refer to; and I would take the liberty to counsel the association not to neglect the earliest opportunity of erasing the objectionable clause, otherwise we shall lose our influence as medical men in securing members on its behalf, and this because the vast majority of the public fight shy of medical men who hold extreme views such as the one embodied in the paragraph I have quoted. I offer these few remarks in no spirit of antagonism or hypercriticism, but as a gentle hint to the association and with an interest in the great cause it is supposed to represent, feeling that it will attain its end better by travelling on its own lines, leaving the total abstinence party to do the same.

I am, Sir, yours truly,

CLEMENT H. SERS.

Queen's Road, Peckham, S.E., Feb. 26th, 1903.

Obituary.

THOMAS PEREGRINE, M.D.

We have to record the death of Thomas Peregrine, M.D., of The Firs, Woking, one of the oldest members of the medical profession, who passed away on Wednesday, February 18th, in his ninety-third year. He took the degree of M.D. at Edinburgh University in 1833, and was awarded the silver medal for physiology. He was attached to St. George's Hospital, London, where he became house-surgeon, eventually completing his medical studies in Paris. In 1837 he became a member of the Royal College of Physicians, London. Dr. Peregrine succeeded his father as a physician in Half Moon Street, Mayfair W., in 1846. He was Senior Warden of the Society of Apothecaries of London, and for many years a member of the Court of Examiners.

Literature.

PSYCHASTHENIA. (a)

In this, as in former works, the author applies the combined psychological and mental method identified with the name of Professor Ribot. The conditions treated of are known to psychiatry under a suspicious variety of names, obsessions, impulses, mental manias,

tics, phobias, neurasthenias, &c. The patients which manifest these conditions have a similar variety of designations for which Janet proposes the older term "doubters"—*scrupuleux*, or more definitely, psychasthenics.

The present volume is the first part of the complete study of psychasthenia. The second part, to be published with the collaboration of Professor Raymond, will contain clinical histories and other data on which the present volume is founded.

The first part is devoted to a careful analysis of the symptoms of psychasthenia, and discusses in detail the form and mode of expression of the various obsessional ideas, such as those of sacrilege, crime, shame—personal or bodily—and hypochondriacal obsessions. The character common to all these ideas is that they refer to acts to be committed by the patient and not to objects of the external world, as in hallucinations and hysterical obsessions. The acts are always of the nature of crimes, at least, in the over-scrupulous eyes of the patient, and are always the most *extreme* of which he can conceive.

From considerations of this nature Janet concludes that the obsessions of doubters are essentially endogenous in character, their apparent exogenous character being a secondary connection engrafted on a pre-existing morbid basis.

In a chapter devoted to the stigmata of psychasthenia, Janet describes the peculiarities of the ordinary mental processes characteristic of this condition. The behaviour of psychasthenics under the hypnotic sleep is discussed in a very interesting chapter. The most noteworthy fact is that contrary to expectation and in contradistinction to hysterics, hypnotic sleep either cannot be induced at all or is very imperfect, especially the forgetfulness of what has occurred during it. As a result, suggestion can only be effected to a slight degree.

Digestive troubles are almost constant, the commonest symptom being loss of appetite; in some cases, however, excessive appetite is noted. Intestinal digestion is also interfered with, obstinate constipation is very common with glairy motions. Muco-membranous colitis is often associated with obsessions and may determine the form of the obsessional ideas. Janet believes that these disorders arise as a result of the nervous depression. After discussing the intellectual and emotional theories the author discusses the psychasthenic theories at great length. He considers the fundamental fact in the production of obsessions to be a lowering of the psychological tension. When this occurs suddenly a condition analogous to epilepsy arises, for which he proposes the term *psycholepsy*.

In the actual treatment of the condition an early and accurate diagnosis is essential, the patient believing that he is suffering from a condition unknown to and beyond the sphere of medicine. The treatment first of all must be directed to the nutrition and hygiene, many cases being cured quickly when these are attended to. Janet speaks highly of a largely vegetable diet and completely interdicts alcohol.

Medicinal treatment is of minor importance. Apart from the treatment of gastro-intestinal conditions it may be summed up in two words—sedative and tonic. Hydrotherapy often gives good results. Static electricity is also beneficial. High-frequency currents are still under trial.

The moral treatment is considered under the headings "Simplification of Life," "Suggestion," "Moral Direction," "Raising Psychological Tension," "Re-education of the Emotions," "The Attention." The place of psychasthenia among the psychoneuroses is discussed at length in the conclusion.

SCUDDER ON THE TREATMENT OF FRACTURES. (a)

The author is to be congratulated upon the fact that three editions have been required in three years.

(a) "Les Obsessions et la Psychasthenia." By Dr. Pierre Janet, Professeur de Psychologie au Collège de France. Paris: Felix Alcan, Pp. 738, avec gravures dans le texte. 1903.

(a) "The Treatment of Fractures." By Charles Locke Scudder, M.D. Third Edition, thoroughly revised, with 645 Illustrations. Philadelphia and London: W. Saunders & Co. 1902.

The object of the book is to serve as a practical guide in the treatment of fractures, therefore all other information is supposed to be treated briefly. There is nothing said about theories, methods of production, pathological anatomy, or histology, but signs and symptoms must, of course, receive recognition.

The first portion is devoted to fractures of the skull, the symptoms of which are poorly stated, operative treatment purposely ignored, and there are some inaccuracies such as: "If there is pressure upon the third nerve at the base of the skull, dilatation of the pupil on the side opposite to the pressure will be noticed." Fractures of the jaws and facial bones are better dealt with, and fractures of the vertebrae, although briefly, are well stated, and the illustrations are excellent. The treatment of fractures of the various long bones is practically put and should prove very useful. There are special chapters on X-ray, gunshot fractures, and the application of plaster dressings, &c., which are good. The volume throughout is profusely illustrated, most of the illustrations being decidedly well done, but some present a complete disregard for perspective.

On the whole the book is well worthy of careful study, and, to counterbalance the few faults we point out, is full of useful hints for any practitioner who requires a trustworthy method of treating the ordinary fractures without wading through wearisome details and rarities.

Literary Notes and Gossip.

DR. DABBS, in his monthly magazine, *Vectis*, gives much of peculiar interest concerning the relations of Tennyson and his doctor.

"MEN AND WOMEN," the new weekly edited by Mr. George R. Sims, in its first number contained an illustrated and sympathetically written article on "Nurses in London."

MR. C. B. KEETLEY, F.R.C.S., has just issued a convenient reprint of his well-known papers on "Gastric Ulcers and their Surgical Treatment."

INVALIDS and others who soon will be flocking southward in search of health and mental recreation with the coming of spring, should not omit to provide themselves with Mr. Edward Hutton's very charming "Italy and the Italians," recently published by Messrs. Blackwood and Sons.

MR. W. R. LETHABY, in his "London Before the Conquest," recently issued by Messrs. Macmillan and Co., furnishes a charming study which will prove of interest to many medical men who are ardent lovers of the ancient ways of our Metropolis.

"TRAVEL," edited by Henry C. Lunn, M.D., in its February issue contains an interesting article on "Where to Stay in Jamaica," which is likely to prove of service to medical men visiting or sending patients to the West Indies.

DR. LEWIS D. MASON in the current number of the *Quarterly Journal of Inebriety*, shows that the indiscriminate sale and use of patent medicines and so-called "cures" for the alcohol and opium habits are not infrequently the cause of the formation as well as continuance of these habits.

THE *Medical Temperance Review* edited by Dr. J. J. Ridge, is publishing a lengthy but very valuable study of "The Pathology of Alcoholism," by Professor G. Sims Woodhead, of Cambridge; and the February issue also contains the report of an interesting address by Sir William J. Collins, M.D., M.S., L.C.C., to the students of St. Bartholomew's Hospital.

WE have received the seventh volume of the second series of the "Index Catalogue of the Library of the Surgeon-General's Office, U.S.A." This stupendous work has now reached its twenty-fourth volume, which includes all titles from hernia to inquiry. To give our readers some idea of the work we may state the present volume includes 6,225 author-titles, representing 2,692 volumes and 8,157 pamphlets. It also contains 13,179 subject-titles of separate books and pamphlets, and 32,522 titles of articles in periodicals. As far as published the two series index 228,465 subjects titles of books; 728,978 subject-titles of journals; 247,821 author-titles; 118,421 author-titles of volumes; and 220,250 author-titles of pamphlets. It is an index to 142,454 bound volumes and 238,772 pamphlets.

DECISION REGARDING ST. BARTHOLOMEW'S HOSPITAL.

At a final sitting of the Lord Mayor's Committee of Inquiry into the affairs of St. Bartholomew's Hospital, held on Monday last, the Committee, after a careful consideration of the evidence taken at the four previous sittings, and after a prolonged discussion, passed the following resolution by fourteen votes to one:—"That, in the opinion of this committee, it is desirable in the public interest to retain St. Bartholomew's Hospital on its present site." It was then decided, on the proposition of the Lord Mayor, to form two sub-committees, the first to deal with buildings, and the second with administration and finance, in order to thoroughly investigate the best means of providing a hospital, perfect in every detail, and brought up to the latest requirements of modern scientific knowledge, on the present site of the hospital in Smithfield. These sub-committees will meet—the former on Mondays, and the latter on Fridays—until their investigations are complete.

Defrauding the Revenue.

A CITY merchant whose misguided ingenuity led him to evade the duty on saccharine by importing it mixed with aniline for subsequent separation, was last week fined £9,300 for his trouble.

Death Under Chloroform.

A WOMAN, age 35, died last week from the effects of chloroform at the Derby Infirmary under somewhat unusual circumstances. She was admitted for heart disease, and one evening she began screaming and struggling. A hypodermic injection of morphia affording no relief, a little chloroform was administered on a towel, but in a few seconds she died. At the inquest an exonerating verdict was returned. The post-mortem examination revealed the fact that she was suffering from nephritis with cardiac hypertrophy.

No Cause of Death Discoverable.

An inquest was held a few days ago on the body of a young man of 20, clerk to the superintendent of Guy's Hospital, who was seized with symptoms of illness after partaking of a sausage, and in spite of treatment died a few hours later. It was found impossible to arrive at a positive diagnosis of the cause of death even after a post-mortem examination, and the inquest was adjourned for the purpose of an analysis of the gastric contents.

The King's Sanatorium.

THE site selected for the King's Sanatorium for Consumption is close to Hindhead Common and about two miles from Haslemere. It is a fine stretch of well-wooded land at an elevation of six hundred feet, and comprises 125 acres. The building will have 100 beds, mostly allotted to necessitous patients. A few beds will, however, be set apart for paying patients at a cost of about £5 a week.

French and English Mortality.

PROFESSOR BROUARDEL, of the French Bureau de l'Hygiene states that the vital statistics of France that are available represent only about 13,000,000 out of a total of 39,000,000 of population, and that the death-rate in 1900 was 21.9 per 1,000 and the birth-rate 21.4. In England the death-rate for the same period

was 18.2 and the birth-rate 28.7, that is, France had 144,000 more deaths and 284,000 fewer births than would occur in the same number of English people. With regard to the causes of mortality, it was found impossible to obtain particulars for comparison, except from towns comprising only about one-third of the total population, but these supply noteworthy figures. London, with its population of 4,500,000 has nearly twice as many inhabitants as Paris, with its 2,500,000. The general death-rate of Paris in 1900 was 20.6, that of London was 18.8. London had 86,007 deaths, Paris had 51,725, or about 4,500 more than London in proportion to its population. The most conspicuous excess was in pulmonary tuberculosis, from which there were 10,072 deaths in Paris as against 7,748 in London, or 4.01 compared with 1.75 per 1,000. From fever there were 912 deaths in Paris against 765 in London, or proportionately rather more than twice as many, while from diarrhoea there were 3,178 deaths in Paris and 3,564 in London, or 1.27 compared with 0.78.

Small-Pox Hospital For Sale.

The Ormskirk Board of Guardians have been ill-advised enough to erect an isolation hospital at the rear of some industrial schools, but the Local Government Board has intervened to prevent its being used for the reception of infectious cases. It is therefore to be put up for sale. It is not often that an opportunity of becoming the owner of a small-pox hospital presents itself.

Coroners and Inquests.

In view of the commotion caused by Mr. Troutbeck's persistence in calling in Dr. Freyberger to make post-mortem examinations, the Public Control Committee of the Council suggest that the names of other skilled pathologists willing to attend to such work should be obtained, and also recommend that local practitioners who have attended persons on whose bodies inquests are held should be summoned to give evidence and paid the customary fee "whenever the coroner is satisfied that their evidence will be material."

St. Thomas's Hospital.—House Appointments.

The following gentlemen have been selected as house officers, their duties commencing yesterday :—

House Physicians.—C. N. Sears, L.R.C.P., M.R.C.S., A. E. Boycott, M.A., M.B., B.Ch.Oxon., B.Sc.Oxon.; W. H. Harwood Yarred, B.Sc.Lond., L.R.C.P., M.R.C.S. (Extension); A. Mavrogordato, B.A.Oxon., L.R.C.P., M.R.C.S. (Extension).

Assistant House Physicians.—O. Hildesheim, B.A., M.B., B.Ch.Oxon., L.R.C.P., M.R.C.S.; H. W. Sexton, L.R.C.P., M.R.C.S.

House Surgeons.—J. W. Rob, B.A., M.B., B.C. Cantab.; T. B. Henderson, M.A., M.B., B.Ch.Oxon.; J. P. Hedley, M.A., M.B., B.C. Cantab.; A. B. Bradford, M.B., B.S.Durh., L.R.C.P., M.R.C.S.

Assistant House Surgeons.—J. E. Adams, L.R.C.P., M.R.C.S.; H. Upcott, L.R.C.P., M.R.C.S.; C. Wheen, B.A.Oxon., L.R.C.P., M.R.C.S.; N. Carpmal, L.R.C.P., M.R.C.S.

Obstetric House Physicians.—(Senior) G. A. C. Shipman, M.A., M.B., B.C.Cantab., L.R.C.P., M.R.C.S.; (Junior) W. M. G. Glanville, B.A., M.B., B.Ch.Oxon.

Ophthalmic House-Surgeons.—(Senior) A. E. A. Iosely, B.A.Oxon., L.R.C.P., M.R.C.S.; (Junior) A. C. Hudson, M.A., M.B., B.C.Cantab.

Clinical Assistants in the Special Department for Diseases of the Throat.—H. S. D. Browne, B.A.Cantab., L.R.C.P., M.R.C.S. (Extension); R. E. H. Leach, B.A. Oxon., L.R.C.P., M.R.C.S. Skin.—T. Guthrie, B.A. Cantab., L.R.C.P., M.R.C.S.; W. M. Strong, M.A., B.C.Cantab., L.R.C.P., M.R.C.S. Ear.—B. S. Jones, L.R.C.P., M.R.C.S. (Extension); A. Bevan, M.B. Lond., L.R.C.P., M.R.C.S.

Clinical Assistants in the Electrical Department.—W. M. Strong, M.A., B.C.Cantab., L.R.C.P., M.R.C.S.; and in X-ray Department.—R. Small, L.R.C.P., M.R.C.S. (Extension).

Obstetrical Society of London.

THE following is the list of officers for 1903:—
President: *Edward Malins, M.D. Vice Presidents: *William Japp Sinclair, M.D. (Manchester); *A. H. Freeland Barbour, M.D. (Edinburgh); John Phillips, M.A., M.D.; Herbert R. Spencer, M.D. Treasurer *George Ernest Herman, M.D. Chairman of the Board for the Examination of Midwives: W. R. Dakin, M.D. Honorary Secretaries: Amand Routh, M.D.; Montagu Handfield-Jones, M.D.; Honorary Librarian: Robert Boxall, M.D. Other Members of Council: Comyns Berkeley, M.B., B.C., *John M. Biggs, Henry Briggs, M.B. (Liverpool), *Murdoch Cameron, M.D. (Glasgow), Charles Owen Fowler, M.D., Charles Arthus Goulet, Walter Spencer Anderson Griffith, M.D.; David Berry Hart, M.D. (Edinburgh), Arthur Corrie Keep, M.D., C.M.Edin., *Arnold W. W. Lea, M.D. (Manchester), Arthur H. N. Lewers, M.D., William Rivers Pollock, M.B., B.C., Harry Campbell Pope, M.D., Edward Reynolds Ray, Thomas George Stevens, M.D., *Walter C. Swayne, M.D. (Bristol), Francis T. Taylor, M.B., *Charles J. Wright (Leeds) Those gentlemen to whose name an asterisk is prefixed were not on the Council, or did not fill the same office last year.

Penny-Wise Economy at Farnborough.

Truth calls attention to the curious policy of the Farnborough District Council in resolving to reduce the salary of the medical officer of health by one-half. The Local Government Board has intimated that it will discontinue its contribution to the salary should the reduction be carried into effect. Our contemporary insinuates that it may possibly be a trick to get rid of the present officer in view of a "little job," but whatever the reason for the change it is obviously one to be deprecated.

The Tallerman Treatment Free Institutes.

A CONFERENCE of the clergy and others interested in the extension of the above charity took place in the Queen's Hall, Portland Place, W., at 2.30 p.m. yesterday March 3rd. The meeting was representative of the most populous of the London parishes, Dr. Sinclair, the Archdeacon of London, having promised to preside. One of the features of the Conference was the work done at this institute among the members of the Hearts of Oak Benefit Society and its further extension. It may be mentioned that here alone some 500 of the crippled poor have derived material benefit from the treatment.

Medical Students' Guide.

THE Royal College of Surgeons, Dublin, has just issued a medical students' guide, giving full particulars of how to become a doctor. Commencing with the preliminary entrance examinations, giving specimens of previous questions set, the fees payable for each term. The entrance examinations will be held this year on March 23rd and September 21st. The guide will be forwarded post free on written application to the Registrar, Royal College of Surgeons, Dublin.

PASS LISTS.

Trinity College, Dublin.

THE following candidates passed the final examination in midwifery, Hilary Term, 1903:—Robert J. Fleming, William G. Harvey, William R. P. McNeill, Charles E. Moore, Joseph Wallace, and Douglas B. Thomson.

Royal College of Surgeons in Ireland.—Fellowship Examination.

THE following candidates having passed the necessary examination have been admitted Fellows of the College: Mr. G. R. Boyce, Mr. J. M. M. Crawford, Mr. A. Harris, Mr. J. M. Keegan, Mr. R. McCombie, and Miss A. M. Thornell. The following passed the primary part of the examination: Mr. E. Sheridan and Mr. R. F. C. Talbot.

Notices to Correspondents, Short Letters, &c.

✍ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial* and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ACCEPTED PAPERS AND CASES.

The following have been received and will appear in due course:—
 Acute Inflammation of the Throat. By Philip R. W. de Santi, F.R.C.S.
 A note concerning the Pathology of Cancer. By J. Jackson Clarke, F.R.C.S.
 On Tuberculous Peritonitis in Children. By George Carpenter, M.D. Lond.
 Oral Sepsis as a Factor in the Causation of Disease. By Alfred Penny, F.R.C.P.I.
 Migraine: with Special Reference to its Treatment. By Jas. Burnet, M.A., M.R.C.P.Ed.
 The Etiology and Prevention of Enteric Fever. By H. V. M. Dillon, M.R.C.P.I.
 Some of the Peculiarities of Influenza. By the same author.
 Somniform as an Anæsthetic in Dental Practice. By T. Percy Fitzpatrick, M.D.
 Case of Primary Cancer of Liver in a Girl. By W. J. Thompson, M.D., F.R.C.P.I.
 W. C. G.—The charges are of such a grave nature that we do not feel justified in giving publicity to them, even over your name. If true, they should be the subject of criminal proceedings, which it lies with you to initiate.
 Mr. GASTON.—We are not acquainted with the formula of the medication in question, and it is not consistent with professional custom to prescribe a remedy, the composition whereof is a trade secret.

THE BEST FLOORING FOR HOSPITAL WARDS.

A CORRESPONDENT will be glad if any of our readers can inform him what is the best form of flooring to put down in wards devoted to the reception of tuberculous patients. Our own opinion is that a good quality of parquet flooring, well waxed and polished, is the most suitable.

NURSE LEVER (Liscard).—We have written a correspondent in Stockholm for the information.

A CANDIDATE.—We think you will find Gant's "Guide to the Examinations" of service. It contains a good many useful hints, copies of examination papers, &c.

PUZZLED.—The population of London, according to official statistics, is now put down at 4,613,812; that of Glasgow at 788,897; Liverpool, 716,810; Manchester, 553,486; Dublin, 378,994; Belfast, 358,680; and Edinburgh 327,441. It is on this basis the weekly statistics of mortality are made.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 4TH.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, London, W.).—8 p.m. Specimens will be shown by Dr. Blacker, Dr. H. Roberts, Dr. Lewers, Dr. Tate, Dr. A. Routh, Dr. Handfield-Jones, and Mr. Bland-Sutton. Inaugural Address:—Dr. Malins (President): Some Aspects of the Economic and of the Antenatal Waste of Life in Nature and Civilisation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. A. Keith: A Research into the manner in which the Abdominal Viscera are maintained in Position in Man and in Animals allied to Man with a view of elucidating the condition generally described as "Glenard's Disease."

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Mr. J. Smith: Clinic. (Surgical.) 5.15 p.m. Mr. A. Carless: The Systematic Examination of Joints in Disease and Injury.

THURSDAY, MARCH 5TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Papers:—Mr. P. L. Mumery: The Value of Arthroscopy in the Treatment of Certain Joint Lesions.—Dr. Sidney Phillips.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. Paper:—Dr. F. J. Tresilian: Some of the Vagaries of Syphilis.

ROENTGEN SOCIETY (20, Hanover Square, W.).—8.30 p.m. Paper:—Mr. F. H. Glew: Spark Phenomena.

FRIDAY, MARCH 6TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. A. Keith: A Research into the manner in which the Abdominal Viscera are maintained in Position in Man and in Animals allied to Man with a view of elucidating the condition usually described as "Glenard's Disease."

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenw'ood, S.E.).—8.45 p.m. Cases will be shown by Dr. M. Dockrell, Mr. C. Ryall, Dr. F. S. Toogood, Mr. C. Williams, and Dr. R. E. Schofield.

SOCIETY OF ANÆSTHETISTS (20, Hanover Square, W.).—8.30 p.m. Papers:—Mr. A. V. Harcourt: New Chloroform Regulating Inhaler by which the Percentage of Chloroform in the Vapour Inhaled can be Positively Controlled. (The Instrument will be shown.)

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—5 p.m. Cases, Specimens, and Instruments will be shown by Mr. F. J. Steward, Mr. C. Baber, Dr. Tilley, Dr. Kelson, Dr. Bronner, and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Dr. W. J. Horne. Clinique. (Throat.) 5.15 p.m. Mr. H. L. Barnard: Acute Appendicitis.

SATURDAY, MARCH 7TH.

MEDICAL SOCIETY OF LONDON (Whitehall Rooms, Hotel Metropole).—7.30 p.m. 130th Anniversary Dinner.

Appointments.

D'EWART, JOHN, M.R.C.S., L.R.C.P. Lond., Third Resident Assistant Medical Officer to Crumppall Workhouse, Manchester.
 DICK, GEORGE, M.B., B.S. Edin., Medical Officer of Health for the counties of Sutherland and Caithness.
 ELLIS, F. M., Medical Officer for the Black Torrington, Bradbury, and Cookbury Districts by the Holsworthy (Devon) Board of Guardians.
 FERGUSON, R. BRUCE, M.A., M.D., B.C. Cantab., M.R.C.S., L.R.C.P., Medical Officer and Public Vaccinator for the Seventh (New Southgate) District of the Barnet Union.
 GRAYSON, F. D., M.R.C.S., Medical Officer of Health for the Rural District of Rochford.
 HUTCHINSON, HENRY, L.R.C.P.I., L.F.P.S. Glas., L.S.A. Lond., Surgeon to the Metropolitan District Railway Provident Society for the suburbs of East Ham, Upton, and Manor Park.
 IRVINE, R. C., M.B., Ch.B. Edin., Senior House Surgeon to the David Lewis Northern Hospital, Liverpool.
 JOHNSON, J. A., M.B., Ch.B. Vict., House Physician to the David Lewis Northern Hospital, Liverpool.
 LINDSAY, CREIGHTON H., M.B., B.Ch. Edin., Resident Surgeon at the Birmingham General Dispensary.
 MURRAY, WILLIAM, M.D., C.M. Edin., Medical Officer of Health for the Warmley (Gloucestershire) Rural District Council.
 O'HARA, W. E., L.R.C.S., L.R.C.P. Edin., L.F.P. & S. Glasg., Junior House Surgeon to the David Lewis Northern Hospital, Liverpool.
 SPEIGGS, EDMUND IVENS, M.D. Lond., Physician to the Out-patients' Department in the City of London Hospital for Diseases of the Chest.
 TUBE, THOMAS SEYMOUR, M.B., B.Ch. Oxon., M.R.C.S. Eng., Lecturer on Insanity, St. George's Hospital, Hyde Park Corner.
 WALKER, TOM, M.R.C.S., L.R.C.P. Lond., Second Resident Assistant Medical Officer to Crumppall Workhouse, Manchester.
 WOOD, C. H., M.R.C.S. Eng., L.R.C.P. Lond., Second House Physician to the City of London Hospital for Diseases of the Chest.

Vacancies.

Durham County Asylum.—Second Assistant Medical Officer. Salary £180 per annum, with rooms, board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.
 Royal Hospital for Sick Children, Glasgow.—Assistant at Dispensary. Salary £100 per annum. Applications to Robert F. Barclay, Honorary Secretary, 91, West Regent Street, Glasgow.
 London Fever Hospital, Liverpool Road, N.—Assistant Resident Medical Officer. Salary £120 per annum, with board and lodging. Applications to the Secretary.
 Poplar and Stepney Sick Asylum District.—Second Assistant Medical Officer. Salary £100 per annum, with rations, furnished apartments, and washing. Applications to Robert Foskett, Clerk to the Managers, Bromley, London, E.
 National Maternity Hospital, Dublin.—Assistant Resident Medical Officer. Salary 50 guineas per annum. Applications to Honorary Secretary (see advt.).
 Bawnborg Union.—Medical Officer. Salary £90 per annum, together with vaccination fees. Immediate application to J. McGovern, Clerk of Union (see advt.).
 Belfast Maternity Hospital.—Matron. Must be a fully-trained and certificated nurse. Salary £80 per annum, with board, residence, &c. (see advt.).
 Trinity College, Dublin.—Professorship of Anatomy. Applications to Benjamin Williamson, Registrar. [See Advt.]

Births.

BRICE.—On February 26th, at Borstal Cottage, Rochester, Kent, the wife of Solomon J. Brice, junior, of a son.
 CÆSAR.—On February 20th, at Dancedale, Minster, Sheerness, the wife of Julius Cæsar, F.R.C.S.I., of a daughter (Eileen Gertrude).
 PRETTY.—On February 25th, at Gas Street, Kettering, the wife of Harold C. Pretty, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

HARNESSE—MACRAE.—On February 27th, at St. John's Church, Mentone, France, H. Nelson Harnesse, M.R.C.S. Eng., and L.R.C.P. Lond. to Florence F. Lucy MacRae, of Collingsbourne, Norbiton, Surrey.
 SOLTAU—WATTS.—On February 23rd, at St. Andrew's Church, Plymouth, Alfred Bertram Soltau, M.D., F.R.C.S., eldest son of George Soltau, of Lordship Park, London, to Edith Mary, elder daughter of the late W. Evans Watts, of Plymouth.
 TAZEWELL—AXFORD.—On February 18th, at St. John's, Bathwick, Bath, Frederick William, son of the late John Tazewell, of Haygrove, Bridgwater, Somerset, to Beatrice Eveline, youngest daughter of the late Richard Axford, J.P., M.R.C.S., L.R.C.P., also of Bridgwater, Somerset.

Deaths.

ANTHONISZ.—Killed by Lightning at Elandsfontein, South Africa, Alfred G. H. Anthonisz, Civil Surgeon, eldest son of Colonel Anthonisz R.A.M.C., Principal Medical Officer Secunderabad and Belgaum Districts. R.I.P.
 FOX.—On February 26th, at 9, Athenium Terrace, Plymouth, Jane wife of Francis Fox, M.R.C.S., and youngest daughter of the late Robert Fortescue, M.R.C.S., of Plymouth, aged 85.
 LONGSTAFF.—On February 26th, at Highlands, Putney Heath, a week after a severe operation, Sara Leam, the beloved wife of George Blundell Longstaff, M.D., aged 51 years.
 WILKIN.—On February 27th, at Hove, Brighton, Henry George Gastrell Wilkins, M.R.C.S., L.R.C.P., late of Bolingbroke, Ealing Common, only son of the late Henry Wilkins, Esq., Surgeon, of the Green, Ealing, W., aged 47.

Original Communications.

A NOTE CONCERNING THE PATHOLOGY OF CANCER, &c.

By J. JACKSON CLARKE, M.B.Lond., F.R.C.S.,
Senior Assistant-Surgeon at the North-West London Hospital, and
Assistant-Surgeon at the City Orthopaedic Hospital.

HAVING for the past ten years closely followed all that has been done towards the solution of the question whether or not cancer is a specific parasitic affection, I have written what follows in order to specify certain changes of opinion that I have elsewhere referred to in a general way and also to express my present views.

The accepted view of the pathology of cancer is based upon the doctrine of cellular pathology first enunciated by Virchow, but it does not involve any doubts of the validity of that doctrine to believe that a parasitic agency is the probable cause of cancer and other forms of malignant disease. In pathology the Darwinian doctrine of evolution has to be considered as well as the cellular doctrine.

To my mind the idea that cancer arises in a perverted habit of epithelial cells seems to contradict the teaching of Darwin in that there could hardly be stability in any species if characters acquired with infinite slowness by natural selection could be so completely lost during the short period of an individual's life. Such general considerations are of some use in directing lines of inquiry the aim of which is to establish facts by observation and experiment.

The area of observation includes biological and pathological data not only concerning cancer and sarcoma but also of other diseases of which only two capital ones, small-pox and syphilis, need be considered here.

To deal, first, with the biological aspect of the matter: When first I brought my observations to the notice of the profession in 1892 the term "psorosperm" was used to designate various sections of the sporozoa. Thus certain myxosporidia were termed fish-psorosperms, and some of the coccidia were often spoken of simply as psorosperms, but the term was never, as some writers appear to think, restricted to the coccidia. At the present time the term may, I think, with advantage be dropped and that of "sporozoa" be used alone for this class of the protozoa.

The most striking advance that has been made in the biology of the sporozoa concern the coccidia, to which subdivision of the sporozoa the malarial parasites belong. The life-cycle of coccidia has been found to include a sexual phase (a), and in the case of the malarial coccidia, an interchange of hosts first surmised by Manson has by Ross (1897) been proved to exist. Thus, in order to complete our knowledge of malaria, it has proved necessary for pathologists to effect a remarkable advance in biology seventeen years

(a) The first description and demonstration of the earlier microgamete stage of coccidium oviforme as a then "new stage" in the development of this parasite was made by myself in a communication to the Pathological Society in 1893. A Committee of the Society pronounced it to be neither new nor important.

after Laveran's discovery of the parasites in human blood.

It is in connection with the general relations of the protozoa that I made the most serious mistake that, in a careful re-examination of my work on malignant disease, I have as yet encountered. In 1893 I showed some sections of a tumour of a cat's lip. Among them was one that showed conjugating gregarines and pseudo-navicellæ—the typical spores of gregarines. This particular section I have since found to be one of an earthworm's seminal vesicle; the assistant who cut the sections for me had accidentally included it among those of the tumour. This discovery invalidates my conclusion that I had found gregarines in a warm-blooded animal, though the sections of the tumour itself show what I still believe to be sporozoa. As showing how little attention had been given at that time to the protozoa by even prominent pathologists it may be mentioned that the pseudo-navicellæ thus inadvertently put forward—the most commonplace of all forms of the sporozoa—were commented on at the meeting as having nothing to do with sporozoa. (a) One well-known pathologist said, "The bodies shown had nothing in common with psorosperms!" Another equally eminent pathologist pronounced the spores of these familiar gregarines to be the eggs of a nematoid! Other instances might be given to show that ten years ago the general body of pathologists had so little knowledge of the protozoa that their criticism made at that time must be taken with the greatest possible reserve.

Progress, in any science of observation like pathology must be from the known to the unknown. In 1891 the Pathological Society of London accepted as sporozoa certain structures that occur in a disease of the urinary tract of man. In 1892-3, when, on the strength of an exhaustive comparison of these bodies in cystic ureteritis with others in cancer and sarcoma, I ventured to express the opinion that the bodies in cancer and sarcoma were of the same nature as those in the cyst of the ureter, a committee representing the society (b) stated that the only basis for my view was my "bare assertion," thus ignoring the position of the Society with regard to the bodies in cystic ureteritis. And when the position of the Society in this matter is examined it is found to be a curious one. Apart from my own article (c), there is no record of any critical examination into the subject contained in the "Transactions" of the Society. They apparently relied solely on the opinion of the late T. S. Cobbold in this matter. Cobbold also expressed the opinion that certain bodies in a sarcoma referred to him by a committee of the same society were also psorosperms. The Society apparently accepted Cobbold's view with regard to the cysts of the ureter, but rejected it with regard to the sarcoma. It will be seen that my reliance upon the value of the floating traditions of the Society was misplaced and that "accepted by the Pathological Society of London" is not equivalent to proof, nor conversely. In 1896 I submitted some of my observations on cystic ureteritis, cancer, and sarcoma, to a distinguished

(a) See *Journal of Pathology*, October, 1893, p. 11.

(b) *Brit. Med. Jour.*, May 26th, 1893.

(c) Pathological Society's "Transactions," 1892.

biologist, and from his guarded manner of treating the subject I came to the conclusion that the Society had been premature in accepting the "psorosperms" of cystic ureteritis as being proved to be sporozoa, and I had been misled by their action to the extent of claiming my demonstration of similar bodies in cancer and sarcoma as proof, though on every point I retained my belief and I set to work to seek other modes of investigation. Bacteriological methods I had tried many times during many years with negative results, and I knew that the "Koch's postulates" method of proof was unlikely to yield results, where sporozoa were concerned. The direct attack having failed, it remained to approach the subject indirectly.

Some disease associated with protozoa was to be sought for and studied on the lines that have so successfully been followed in the case of malaria, where a close study of the varying phases of the disease in relation to the varying phases of the sporozoa in the blood had led to the understanding of the disease without any recourse to "pure cultures" or other methods so useful in bacteriology. The pathology of small-pox is in itself of the greatest interest, and I believe by analogy it throws a light on that of syphilis and of cancer. (a) I may now refer to some aspects of our knowledge of these three capital diseases.

Small-pox.—The earlier observations of protozoa in variola made by Van der Loeff and L. Pfeiffer, might have long remained ignored had not Guarnieri, by a simple experiment, brought them into prominence. The cell-changes that follow vaccination can be followed in the epithelium of the cornea with a clearness that is impossible in the stratified epithelium of the skin. About the end of the second day nearly all the epithelial cells about the seat of inoculation contain the now well-known bodies that are readily visible in both the fresh and the hardened cornea, and in both unstained and stained preparations. When unstained these bodies appear as bright homogeneous points which stand out from the rest of a section by reason of their high refracting power; in stained preparations they recall the bodies Russell (b) described in cancer in 1890. Towards the end of the second day some of the intra-cellular bodies stain more darkly at their centre than at their periphery. These features have been recognised by various authors, but if no further evidences of organisation in the bodies were afforded by careful histological examination I do not think anyone would be justified in claiming the bodies as protozoa. On the other hand, all attempts to explain the bodies as other than parasitic cells have failed; the elaborate explanation worked by Hückel having recently been found by v. Wasielewski (c) to be invalid. The bodies are so far specific that Guarnieri's experiment may be taken as a test of the activity of any specimen of vaccine lymph. The forms that led me to conclude that the bodies are protozoa are best seen in the vaccinated cornea of guinea pigs. After the second day leucocytes increasingly invade the corneal epithelium and swelling and other changes occur in the epithelial cells, but after a close and prolonged study of the bodies of cystic ureteritis and of the sporozoa I think it is possible to trace, in part at least, the after history of these vaccine bodies as is shown diagrammatically in Fig. 2. The destruction of the epithelium of the cornea is much more widespread than for convenience it is represented in the diagram. To Hückel my interpretation of some of these extra-cellular bodies appeared capricious, but the same view has since been taken by F. J. Bosc (d) in a comparative study of sheep-pox, vaccinia, and cancer. In conjunction with the observations of other authors my own investigations have convinced me that both the intra-cellular and the extra-cellular bodies are parasitic. If so, are they vegetable or animal—protophyta or protozoa? Granted their parasitic nature it may still be asked whether it is of

much moment which category they belong to? For my part I think it is of great moment. It is hard to understand how some authors who a few years ago ascribed certain bodies in cancer to the protozoa now describe them as yeast-cells without apparently realising the magnitude of their change of view. It is true that among the mycetozoa are some forms that botanists claim as protophyta, but with regard to the blasto- and sacharo-mycetes no such uncertainty exists. The aggressive, highly-specialised parasitism of some of the protozoa gives them a totally different import from the more passive bacteria and fungi. The pyogenic bacteria that are of prime importance in wounds where the protecting epithelia are broken are harmless on unbroken surfaces. No known yeast-fungus causes a definite and spreading infection of epithelium such as could give rise to appearances similar to those indicated in Figs. 1 and 2.

It has been stated (a) that the bodies seen in the vaccinated cornea differed essentially in their staining reaction and in their appearance from those described as protozoa in cancer. On the contrary, I found (b) that there was a close similarity between them, and that through a larger series of forms than was usually recognised.

My contention has quite recently received important confirmation. Monckton-Copeman and Mann (c) writing of vaccine lesions in skin, observe:—"Clarke rightly points out that many cells appear similar to those found in cancer." It has been objected by the late A. A. Kanthack that if similar parasites are alleged to cause diseases as dissimilar as small-pox and cancer the idea of specificity is lost. In answer to this it must be explained that I do not wish to infer that there is any closer connection between the parasites of variola and those of cancer than there is between the bacilli of glanders and those of tubercle or any other pathogenic bacilli. I do, however, feel that if we cannot determine the causal agent of vaccinia, the virus of which is almost an article of commerce, and can readily be made to reproduce the affection in animals, we are hardly likely to ascertain the cause of cancer. It has recently been suggested that the parasite in vaccinia may be so minute that our present microscopes are unable to render it visible. Before lending ourselves to such a vague leading it will be wise to come to a conclusion regarding the bodies indicated in Figs. 1 and 2 (see description of illustrations). The nature of these bodies is being seriously considered in all civilised countries.

Syphilis.—The question of the presence and the meaning of protozoa in syphilitic lesions has been less extensively worked out than is the case in vaccinia and cancer, but the documents relating thereto are of much the same kind. Doehle (d) found flagellates in the blood in the febrile period of the disease and three years later I described in primary, secondary, and tertiary skin lesions (e) bodies resembling those that occur in vaccine lymph and variolous lesions, and I also repeated, I think successfully, Guarnieri's experiment, using matter from a chancre in lieu of vaccine. This latter observation has been confirmed by E. Pfeiffer (f) who, however, was unable to decide whether the appearances were due to protozoa or to protophyta.

Malignant Growths.—Guiseppe Pianese has produced the clearest, fullest, and fairest adverse criticism (g) of the work of those who have described as parasites certain histological appearances met with in malignant growths, and his work may be regarded as a summation of conservative pathological opinion up to the date of its appearance.

Sarcoma.—One of the first descriptions of protozoa

in sarcoma was given by myself (a) in 1893. On re-examining the section from which the figures in this article were drawn, I have to confess that I was in

error with regard to what I described as amoeboid free psorosperms in Fig. 3. The larger intra-cellular bodies in Figs. 1 and 3, and the encapsuled reticulated bodies, I still regard as parasites. Also the bodies in different sarcomas that I put before the Committee of the Pathological Society (b) I still regard as protozoa. One of the most important contributions to this subject that has appeared since then is that by Bellingham Smith and the late Dr. Washbourn (c) on infective sarcoma in dogs. Dr. Washbourn kindly gave me two of his sections; after bleaching and re staining I have found in them bodies that I regard to be protozoa.

Cancer.—It is impossible to go into the mass of work that has appeared in relation to cancer during the past ten years. I may, however, refer to my first communication on the subject (d). Certain bodies that I then described were afterwards seen by Korotneff and described under the somewhat fanciful designation of "Rhopalocephalus carcinomatosus." Quite lately F. J. Bosc (e) has recognised similar

bodies in sheep - pox, and remarks:—"The Rhopalocephalus carcinomatosus, described by Korotneff, has not been favourably received. I think, however, that there is now reason to reconsider this matter." Gaylord refers to another of the bodies that I showed before the Committee of the Pathological Society, whose report (May, 1893) I have referred to above, as follows:—"In an article published by Jackson Clarke, *Centralblatt für Bakt.*, Vol. 16, Fig. 6 of Part III., is a most typical representation of these bodies"—i.e., the bodies most recently described by Plimmer (f) as the characteristic parasites of cancer. Gaylord (g) has very carefully re-examined the work of Sanfelice, Plimmer, and others who have accepted Sanfelice's view, and he has come to the conclusion that these authors are mistaken in their interpretation of certain "cancer - bodies" as yeast - cells. Gaylord's work, in several important particulars, that I need not here enumerate, confirms the conclusions that I arrived at ten years ago.

FIG. 1.

FIG. 2.

In the course of the laboured beginnings of any new way in science, premature expressions of finality are rarely wanting, and with regard to cancer it has already been said by two of those who have recently worked at the subject that the microscope has done all that it can do in relation to cancer. I do not hesitate to express the opinion that there is yet much to be done by means of the microscope; for instance, in comparing cancerous with sarcomatous, syphilitic, variolous and other lesions; and in the comparative study of all of these with known protozoan infections. Another wide field is the study of the blood in the infective fevers in the light of the clinical phases of these fevers in ways that the parasitology of malarial affections suggests. Evidences of vital activity among the elements of morbid tissues are to be carefully sought for. After keeping the familiar oval bodies that occur in molluscum contagiosum (a benign epithelioma) in a moist chamber for a few days I have observed changes that can only mean that these bodies are protozoa which break up into flagellated swarm-spores (a). Roughly, twenty years were required for bringing our knowledge of the parasites of malaria to its present degree of completeness, and the process involved the increase not only of pathological, but also of biological knowledge—a two-sided inertia which fully accounts for the length of time that, in the absence of a touchstone such as Koch's postulates, has been required for our enlightenment.

DESCRIPTION OF ILLUSTRATIONS.

FIG. 1.—Shows the ordinary appearance of a stained section of a rabbit's cornea twenty-four hours after vaccination. The seat of inoculation is in the middle of the section.

FIG. 2.—Shows a diagrammatic representation of a guinea-pig's cornea seventy-two hours after inoculation. At the margins of the section are small intra-cellular bodies similar to those of Fig. 1. Towards the middle of the section are in turn (1) larger intra-cellular bodies with a denser central part; (2) and (3) intra-cellular bodies with a vesicular nucleus within which are particles of chromatin; (4) an intra-cellular cluster of nucleated bodies, and various bodies lying free on the surface, viz., (5) an amœbiform body, (6) a round body with peripheral granules, (7) an oval body showing nuclear divisions, and, finally (8) a round body containing nucleated subdivisions.

HUMAN AND BOVINE TUBERCULOSIS; THE POSSIBILITY OF INFECTION FROM CATTLE. (b)

By NATHAN RAW, M.D., M.R.C.P.Lond., F.R.S.Edin.,

British Representative on the International Committee for the Prevention of Consumption; Physician, Mill Road Infirmary; Physician, Sanatorium for Consumption, Liverpool.

PROFESSOR KOCH, the greatest authority on tuberculosis, in an address at the International Congress in London in 1901, greatly disturbed the scientific world by announcing his now well-known theory that human and bovine tuberculosis were separate and distinct diseases, and that bovine tuberculosis could not be conveyed to man. Again, in 1902, in an address which I heard him deliver in Berlin, he reiterated all his statements and expressed himself as convinced on the point. The great majority of medical men in this country, however, have firmly believed that there was a

 (b) Abstract of paper read at the meeting of the Liverpool Medical Institution, February 26th, 1903.

probability of tuberculosis being conveyed in milk, especially to children, whilst they also were of opinion that the disease was identical in man and animals. Now it must be admitted that the great body of experimental evidence is in favour of Koch's first contention that the two diseases are distinct, and that it is almost impossible to produce a general tuberculous infection in cattle by inoculating them with human bacilli from sputum.

Out of 2,000 cases of phthisis pulmonalis, I have only seen the glands and the joints affected in six cases, and in the late stages one sees the intestine and peritoneum involved. Phthisis pulmonalis is essentially a disease of young adult life. It is rare to see it as a primary affection under the age of twelve, the great majority of deaths taking place between the ages of thirty and forty, as my tables will show.

On the other hand, strumous or tuberculous joints, enlarged joints, spinal disease, and abdominal tuberculosis with *tabes mesenterica* are essentially diseases of infancy and childhood, and are only rarely seen in adult life.

From these general clinical and pathological observations I am inclined to think that primary intestinal tuberculosis, *tabes mesenterica*, and other tuberculous affections of the serous membranes in children are probably bovine tuberculosis, conveyed by milk, and are not in any way related to human tuberculosis, although the bacillus of Koch is found in them all and is indistinguishable.

I will claim your indulgence when I attempt to lay before you all the evidence which I can, in support of my view that *tabes mesenterica* is caused by bovine tubercle bacilli in milk.

Veterinary authorities, such as Nocard, Bang, Dollar, and McFadyean, agree that about 30 per cent. of dairy cattle suffer from tuberculosis, and recent official figures from different parts of England show that in London dairies 25 per cent., in Edinburgh 40 per cent., Midlothian 23 per cent., Durham 19 per cent., and Yorkshire 25 per cent. of the cows are tuberculous. The point I wish to make is this: The infection commences in the mesenteric glands from the intestine, slowly spreads to the retro-peritoneal glands, then through the diaphragm to the glands in the posterior mediastinum, and finally to the lungs. If the child lives long enough the brain may be affected too. At the post-mortem this process has been corroborated again and again, and I will show you a case where there is extensive caseation of the mesenteric, retro-peritoneal, and portal glands, and only a few grey tubercles at the base of both lungs. Taking all these facts into consideration, and after a careful study of tuberculosis in all its forms during the last ten years, I am of opinion that bovine tuberculosis is very virulent for children, and is accountable for *tabes mesenterica* and other varieties of abdominal tuberculosis; in fact, I believe it to be more virulent to children than human tuberculosis. How many scores of strong, healthy, vigorous children and adults do we see who have suffered from tuberculous glands in the neck with never a symptom in after life!

Surely these people cannot be classed as tuberculous?—they have suffered from a mild infection of tubercle bacilli which was in all probability bovine in origin and absorbed from milk.

There is much evidence also to suggest that acute miliary tuberculosis, especially that of the typhoid

form, is in reality a bovine tuberculosis produced by food ingestion. Since the two diseases cannot exist together in cattle, may it not be that they cannot exist together in man? and that the serum of a cow affected with tuberculosis might have a curative effect in a case of pulmonary phthisis exactly on the same lines as small-pox and cow-pox? Who knows? It is only an idea, but in the treatment of such a fell disease anything is worth thinking about.

It has been pointed out before that the danger is greatest when cow's milk is used exclusively and tubercle bacilli introduced day by day, as it is only when large numbers of bacilli are used that infection is likely to become general. It would appear, therefore, that infants and young children with a feeble power of resistance are susceptible to bovine tuberculosis, more especially if fed for a prolonged period on infected milk, that as age advances the susceptibility is decreased, until at adult life there is little risk to more than a purely local affection of the glands of the neck, which, however, may occasionally extend directly to the lung and even a general miliary tuberculosis.

Legislation.—Considering that tuberculosis is so common, and is even increasing in this country among dairy cows, something ought to be done by the Legislature to prevent the wholesale distribution of tuberculous milk to the public. I do not advocate any harsh measures, as I am quite sure that every farmer and dairyman in the country would assist in every way to stamp out tuberculosis in cattle; but I certainly would make it a penal offence for any person who knowingly supplied milk to the public from a cow suffering from tuberculosis of the udder.

A more rigorous inspection of dairy cattle should be made by the health authorities, and as it is perfectly easy and certain by the tuberculin test to diagnose a tuberculous cow, there should be no difficulty in at least eradicating the disease from dairy cattle.

The onus of responsibility of supplying pure milk to the public should not rest on the health authority, but on the producer, and although the health authority can do a splendid and humane work by providing the community with sterilised milk at a cheap rate, still the real responsibility must lie with the man who actually delivers milk for sale to the public.

I conclude by expressing the opinion, based almost exclusively on clinical and pathological evidence, that human and bovine tuberculosis are separate and distinct diseases as shown by Professor Koch; *but*, that the human body is susceptible to both, and especially to bovine tuberculosis in the early periods of life. The two diseases are so rarely seen together in the human that there seems to be some ground for presuming that they are antagonistic to each other, and that bovine tuberculosis may possibly confer an immunity against human tuberculosis. If this opinion should prove correct, I venture to submit that it would entirely reconcile the conflicting opinions which have been so frequently expressed during the last two years on this most terrible of all diseases.

LORD STRATHCONA will take the chair at the Festival Dinner to be held in aid of the funds of University College Hospital, at the Hotel Metropole, on Wednesday March 18th.

A REPORT OF FOUR CASES
OF
ACUTE SEPTIC INFLAMMA-
TION OF THE THROAT,

WITH BACTERIOLOGICAL EXAMINATION OF EACH. (a)

By PHILIP R. W. DE SANTI, F.R.C.S.,

Surgeon to the Nose, Throat, and Ear Departments at the
Westminster Hospital.

In an extremely able and important paper, read by Sir Felix Semon before the Fellows of the Royal Medical and Chirurgical Society on April 23rd, 1895, and entitled "On the Probable Pathological Identity of the Various Forms of Acute Septic Inflammations of the Throat and Neck hitherto described as Acute Œdema of the Larynx, Œdematous Laryngitis, Erysipelas of the Pharynx and Larynx, Phlegmon of the Pharynx and Larynx, and Angina Ludovici," the author very clearly pointed out the extreme confusion that exists in the nomenclature and classification of these inflammations, and expresses his conviction "that the various forms of acute septic inflammations of the throat and neck, hitherto considered as so many essentially different diseases, are in reality pathologically identical; that they merely represent degrees varying in virulence of one and the same process; that the question of their primary localisation and subsequent development depends, in all probability, upon accidental breaches of the protecting surface through which the pathogenic micro-organism which causes the subsequent events finds an entrance; and that it is absolutely impossible to draw at any point a definite line of demarcation between the purely local and the more complicated, or between the œdematous and the suppurative forms.

To prove these convictions he gives clinical details in order of ascending severity of fourteen cases which had come under his own personal observation, but, at the same time, confesses that bacteriological evidence in the cases is unfortunately conspicuous by its absence. He also expresses a hope that subsequent observers will test the correctness of the views put forward by himself as to the probable identity of the various acute inflammations of the throat and neck.

Since the reading of Semon's paper I determined in any case of acute septic inflammation of the throat that might present itself to my notice to keep a careful record, and to test, if possible, the nature of each case bacteriologically, so that if I had a sufficiency of cases I might be enabled to come to some definite conclusions either for or against Semon's views, which views, at the discussion which followed his paper, were more or less fiercely attacked.

My experience since 1895 of these so-called acute septic inflammations of the throat and neck has been limited to four very distinct and definite cases, notes of which I herewith give, according to Semon's plan, in their order of ascending severity.

CASE I.—A male patient, æt. 48, admitted May 10th, 1899, with a deep-seated cervical abscess reaching from just below the right mastoid process to the level of the cricoid cartilage, and extending under the right sterno-mastoid muscle to near the mid-line of the neck. There was a history of old suppuration of the right middle ear, and pressure on the cervical abscess caused pus to well out of

the right external auditory meatus. An examination of the tympanum showed complete absence of the membrana tympani: there was some pain caused by pressure over the mastoid process, but there was an absence of any redness, swelling, or œdema over the process. I suspected a perforation of the mastoid process on its deeper digastric aspect (Bezold's perforation), and considered the deep-seated cervical abscess to be due to infection through this perforation.

I opened up the mastoid antrum and cells, evacuated pus and granulation tissue, and found a somewhat ragged aperture on the deeper aspect of the process communicating with the abscess in the neck. The mastoid and cervical abscesses were both thoroughly opened and drained, and the patient progressed favourably until June 2nd, on which day the temperature rose to 102° F., and there was general malaise and pain. Three days later cutaneous erysipelas commenced on the left cheek; later on the same day it had spread to the left side of the neck, the whole left side of the face and also across the middle line of the face and neck to the right side.

There were also patches of redness all over the back down to the lumbar region. In the evening the temperature was 103.4°, and the man was very ill. Soreness of the throat was complained of, and examination showed a bright red swollen condition of the posterior pharyngeal wall and of the whole of the soft palate, especially the uvula. Cultures from the mucus of the throat showed mainly *Streptococcus pyogenes* with some staphylococci.

Antistreptococcus serum, 10 c.c., was injected into the abdominal wall June 2nd. June 3rd.—Twelve noon, another 10 c.c. was injected. Swelling of the eyelids and throat less. 4th.—Face less swollen, also eyelids. Rash almost entirely gone from the back. Temperature in the evening 101.6°. Ten c.c. of serum injected. Temperature fell at midnight to 99.2°. Urine normal. 5th.—Cheeks still red but less swollen. Rash almost gone from the rest of the face and neck. Throat still red but not swollen. 7th.—Desquamation. Throat normal. From this date the patient made an uninterrupted recovery.

CASE II.—*Acute œdematous tonsillitis and pharyngitis*.—A man, æt. 32, came in 1898 complaining of swelling in the neck and sore throat. His illness had started with headache, shivering fits, and sickness three days before I saw him. These symptoms were soon followed by much pain and dryness in the throat, the pain, especially on swallowing, having greatly increased for the last twenty-four hours. For two days there had been weakness of the voice, and the patient could only just use his voice in a whisper. The man looked ill, his temperature was 104.6°, his pulse rapid (120) and compressible, and there were enlarged and tender glands on both sides of the neck. The urine was normal.

Examination of the throat showed intense redness and swelling of the right tonsil, of the whole of the soft palate and uvula, and a dark red glazed and swollen condition of the posterior pharyngeal wall. There was also slight œdema of the epiglottis, but the rest of the larynx, which could be fairly seen, was neither congested nor swollen. Swab cultures were taken from the tonsil and pharynx, and examination by the pathologist showed *Streptococcus pyogenes* infection. I advised the patient to come into the hospital at once, but although the

(a) Abstract of Paper read before the Royal Medical and Chirurgical Society, February 10th, 1903.

gravity of the case was clearly put before him he refused and left the hospital. I never saw him again, and the subsequent history of the case is therefore unknown to me.

CASE III.—*Acute gangrenous inflammation of the throat.*—A man, æt. 21, came to my throat clinic at Westminster Hospital, December 2nd, 1901, complaining of sore throat, pain and great difficulty in swallowing, loss of voice, and general malaise. His throat trouble had commenced two days previously, and he had rapidly got worse. He could not in any way account for his illness, there being no history of injury, old ulceration of the throat, or of any people in the house he lived in suffering from throat trouble. The patient worked in an oil shop and was indoors most of the day. He had had influenza six years previously, and had had slight sore throat once or twice since, but this had got well in a day or two after using chlorate of potash gargle.

He looked very ill and pale, and complained of aching pains all over. His temperature was 101.2° , pulse very frequent (120) and soft. Could only speak in a whisper and with difficulty; no dyspnoea present. Urine normal.

The uvula was enormously swollen, intensely red, and the lower half black and gangrenous. The inflammation at the base of the uvula had spread to the soft palate, which was red and œdematous, and to the tonsils, the latter being similarly affected, but to a less degree. The posterior pharyngeal wall was red and slightly swollen. Laryngoscopic examination showed the epiglottis to be slightly swollen, especially at its base, and there was very extensive œdematous swelling of the left ary-epiglottic fold, the latter looking like a large yellowish polypus; the right half of the larynx was unaffected.

The patient was at once admitted. On admission it was found that he could not swallow at all, not even liquids. A swab culture from the uvula revealed the presence of *Streptococcus pyogenes*, and some staphylococci; no diphtheria bacilli.

Immediately after admission, the house physician, Dr. Watson, injected into the right lumbar region 20 c.c. of antistreptococcal serum. The patient at once began to improve and left the hospital quite well on the 20th.

I subsequently saw him on three or four occasions and found the throat quite normal.

CASE IV.—*Acute pharyngitis due to Streptococcus pyogenes followed by septicæmia, deep lardular inflammation, and pericarditis.*—This case was under the care of my friend and colleague Mr. W. G. Spencer. A man, æt. 21, was first taken ill October 16th, 1898, with a sore throat, followed by swelling in the neck. He gradually got worse and was admitted under Mr. Spencer on October 24th. He was then partly unconscious, had great pain and difficulty in swallowing. The temperature was 101.4° , having been 103° during the night; the pulse was 120, small, and of low tension; respirations 30 and quiet. The mouth could only be partially opened; the tongue was swollen and brown, and the posterior pharyngeal wall was covered with brown sticky mucus, but no membrane. The left side of the neck was much swollen, red, brawny, and œdematous. An incision had been made by the house-surgeon at the posterior border of the sterno-mastoid muscle, from which a sanious fluid had escaped, but no pus. On auscultation a loud pericardial friction rub could be heard.

The mucus from the throat and the discharge from the wound in the neck were examined by Dr. Blaxall, the bacteriologist, and he found both in cover-glass specimens and upon cultivation mainly *Streptococcus pyogenes*. In the cultivation from the throat, a yeast, *Staphylococcus albus* and a few bacilli were also found.

At 9.30 p.m. on the 24th, eight days after the first signs of the illness, 10 c.c. of antistreptococcal serum were injected, a second dose at 6 a.m., and a third at 4.20 p.m. on the 25th, and a fourth on the 26th. The effect was remarkable, the patient beginning to rally at once.

On the 27th the temperature fell to 98° , and did not rise above 100.8° . The patient was conscious and had no pericardial pain. The tongue was less swollen and more moist, and the pharynx was in a cleaner condition. The incision in the neck was discharging pus from deep-seated glands.

The patient left the hospital on December 14th to go to a convalescent home, the pulse and temperature being then normal, and the wound in the neck healed.

These four cases, brief notes of which I have given, constitute the series of acute septic inflammations of the throat and neck that have come under my personal observation since 1895. They are a series smaller, of course, in number, but quite parallel with Semon's cases. They were all four very marked types, and therefore easy to diagnose. I have no experience of the very mild yet distinct cases related by Semon.

It is obvious that without any adequate and expert bacteriological examination of these milder cases—and Semon admits the absence of a bacteriological examination—it is open to any critic to deny the certainty of their septic origin, and to conclude that from the mildness of the symptoms the cases were clinically catarrhal inflammations pure and simple.

Of my four cases, two, in my opinion, were analogous to Semon's milder cases, namely, my first case, in which the patient suffered merely from swelling and redness of the uvula, soft palate, and pharynx, but in which the sore throat, such as it was, was undoubtedly of septic origin, being part of a definite extension of a well-marked case of cutaneous erysipelas to the throat, and in which a cultivation from the throat showed *Streptococcus pyogenes* infection; and my second case, exactly analogous to No. 4 in Semon's series as regards the parts attacked, namely, the tonsil, pharynx, and epiglottis, and in which a cultivation again showed streptococcal infection.

Now I consider these two cases, in which the bacteriological examination was made by an expert, and in both of which streptococcal infection was found, and in both of which the symptoms were, especially in the first case, of a more or less mild character locally, prove undoubtedly that Semon's milder cases were probably of a septic nature, as suggested by him; and this is further strengthened if we look at the cases from their clinical aspect. These milder cases, as well as the more severe types of acute septic inflammations of the throat, are characterised by their sudden onset, rapidity of progress, absence—as a rule—of any demonstrable cause, the limited distribution of the inflammation in contradistinction to the more general distribution in catarrhal conditions, the much greater amount of œdema and redness, and the well-marked and severe constitutional sym-

ptoms. In both my first and second cases these characteristics were well marked in every way, and I conclude, as regards Objection No. 1, that bacteriological investigation has proved that these milder cases can be of septic origin, and that the clinical symptoms are distinct from those of a catarrhal inflammation.

The objection that the different localisation in Semon's cases, namely, whether originating in the pharynx, larynx, or cellular tissue of the neck, spoke against their being identical cannot possibly hold good. The different localisation of these septic inflammations of the throat must surely depend on the resisting powers of the parts attacked, an accidental breach of surface, possibly quite minute, or a pre-existing condition of catarrh, rendering the part more susceptible to infection.

As pointed out by Semon, diphtheria remains diphtheria whether it primarily attacks the tonsils, pharynx, nose, conjunctiva or vulva; and it is the same with these acute septic inflammations of the throat.

In my four cases the posterior walls of the pharynx were primarily attacked in two, the tonsils in another, and the uvula in the fourth case, yet they were all identical diseases, as proved by their bacteriological results, and they only differed clinically in so far as the severity of the symptoms varied.

I am not dealing in this communication with the disease described as Ludwig's angina, or, as I prefer to call it, submaxillary cellulitis; but I would say incidentally that I have had under my care some six or more such cases, and in so far as my memory serves me, in three or four it was definitely made out that the infection started from a lesion in the floor of the mouth. There are no records of the bacteriological examination of these cases.

In respect of the argument "that the variations in the fever curve in Semon's individual cases also seemed to point in the direction that this fever was caused by different and not identical processes," I would point out that the temperature in my four cases varied between 101.4° and 104.6° , and although I consider that the temperature in this class of case is bound, as in other similar diseases, to vary, especially according to the resulting inflammation, whether œdematous, suppurative, or gangrenous, and according to the amount of the poison absorbed, yet I venture to think that further observations will prove that these acute septic inflammations of the throat are almost invariably accompanied by some degree of more or less severe fever.

At any rate, in the limited number of cases I have seen there has always been fever, although no fever curve that I could adjudge characteristic of the disease in question; yet I consider all my cases identical in nature.

Semon held that the fact of the exudation sometimes being of a serous and sometimes of a purulent character most powerfully combated the view that these inflammations were identical in nature. This objection has to be investigated entirely from a bacteriological point of view.

According to recent standard works on bacteriology, the present-day opinion of authorities best calculated to form competent conclusions on the matter is as follows:—

1. That the *Streptococcus pyogenes* and other pyogenic cocci can produce, apart from purulent inflammation, all other forms of inflammation, such

as serous, fibrinous, hæmorrhagic, and gangrenous inflammations.

2. That the variety of inflammation resulting depends (a) on the quantity, (b) the virulence of the organism introduced into the system, (c) the resisting power of the subject inoculated.

It seems to me, therefore, that these conclusions are amply sufficient to account for the differences in not only the fever curve of these various septic inflammations of the throat, but also for the differences in the kind of inflammation resulting, namely, œdematous, purulent, or gangrenous.

Treatment.—In all cases suspected to be of the nature of an acute septic inflammation of the throat it is absolutely essential to have a competent bacteriological examination made of the secretions, both cover-glass and culture preparations being made, and if possible inoculation experiments carried out. If bacteriological investigation prove the presence of the *Streptococcus pyogenes* there should be no delay in injecting the patient with the antistreptococcus serum. The marvellously good results that ensued in the almost hopeless case, No. IV. of my series, from the injection of this serum, together with the equally good results accruing from the same treatment in Cases I. and III., leave no doubt in my mind that in cases in which the streptococcus is found we have a most efficacious remedy in antistreptococcus serum; and I feel sure that in the fatal cases recorded by Semon the results might have been different if this treatment had been in vogue and carried out. It is, however, most necessary to emphasise the fact that unless the streptococcus is identified as the cause of the disease it would certainly be useless, and, indeed, extremely hazardous, to use the streptococcus antitoxin. For its success the *Streptococcus pyogenes* must be discovered in the secretions of the affected part or parts.

The dose to be injected depends on the age and condition of the patients: in an adult I consider 10 to 20 c.c. sufficient as an injection; in children the dose should be proportionately smaller.

In addition to streptococcal antitoxin injections I think the free administration of large doses of the liq. ferri perchloridi of service.

If œdema be very marked, and especially if the larynx be attacked, free scarification should early be resorted to, and tracheotomy performed as soon as the breathing becomes markedly embarrassed.

If the inflammation be gangrenous, the gangrenous parts other than the larynx itself should at once be thoroughly rubbed over with pure carbolic acid; this local treatment had excellent results in my Case III.

These are the main lines of treatment I would advocate. Among adjuncts are the administration of stimulants according to the state of the pulse, the use of disinfecting vapours, such as the vapor creosoti, and the spraying of the throat before the ingestion of food with cocaine or cocaine or menthol sprays.

The external application of cold by means of ice coils, &c., to the neck I deprecate, as I hold that these cold applications only tend to further devitalise already damaged tissues.

In similar diseases, especially of an erysipelatous nature, attacking other parts of the body, cold applications are contra-indicated, especially if suppurative or gangrenous inflammation threatens or has already ensued.

The Lettsomian Lectures
ON THE
CONDITIONS WHICH MODIFY THE
CHARACTERS OF
INFLAMMATIONS OF THE SKIN
AND THEIR
INFLUENCE ON TREATMENT.

DELIVERED BEFORE THE MEDICAL SOCIETY OF LONDON
By H. RADCLIFFE CROCKER, M.D., F.R.C.P.,
Physician to the Skin Department, University College Hospital.

ABSTRACT OF LECTURE II.

IN the previous lecture the influence of the microbe only was discussed, but in the majority of cases the state of the patient is equally important. Even age is often an important factor. Thus pus cocci easily infect children, and free suppurations are therefore often induced in them, and if they are not treated at an early stage the cocci may penetrate deeply and infect the general system. In a new-born infant a surface lesion usually takes the form of a bulla, with clear contents; but in older children the vesicular and pustular forms of impetigo contagiosa occur. Adults often resist it altogether, or the lesion may only appear as an excoriation. Ecthymatous sores, however, occur in severely itching diseases, like pediculosis corporis, but though deep they are seldom abundant. They are, however, vulnerable to both boils and carbuncles, and the latter may spread to a fatal extent. Suppuration in the aged is also liable to go on to gangrene, without previous suppuration, as seen in ophthalmic herpes zoster.

Gangrene is also frequent in infants in multiple patches, which may supervene upon any pustular eruption, such as a miliaria, but the most common cause is varicella, and it occasionally develops on recent vaccination lesions. This is supposed to be due to the *Bacillus pyocyaneus*, and the liability ceases after the age of three years. Formidable as these cases may be, and many are fatal if allowed to run their own course, the extension of the gangrene can be checked if at an early stage injections of carbolic acid solution are made in the neighbourhood of each lesion, as in the treatment for carbuncle. These latter are rare in the young, fairly common in middle-age, and still more so in the old. Boils, on the other hand, have no age restrictions.

Old age is of itself a strongly disposing factor for ordinary eczema, and it often spreads rapidly and extensively in a senile skin, partly from the defective nutrition of the skin itself, partly from the defective elimination of the tissue-worn viscera, especially the liver and kidneys. The indications for treatment, therefore, are to assist these worn-out organs as far as our means will permit. On the other hand, the seborrhœides are rarely seen in old age. Heredity plays an important part in this and other tissue proclivities to certain forms of inflammation, such as psoriasis.

Turning to other causes, experience indicates toxin absorption as one of the most powerful factors in the production of skin inflammations. While auto-intoxication from the intestines is the most frequent source of these toxins and ptomaines, it is possible, but more difficult to demonstrate, that absorption of injurious substances from other viscera may also occur, and some cases suggest

that where dermatitis appears to have been excited by sudden chills to the surface, the explanation is that these produced sudden contraction of the surface vessels followed by dilatation, and that during the latter toxins were absorbed from the intestines and other organs and were distributed peripherally and excited eruptions, the particular kind apparently depending more on the individual than on the toxin.

The influence of the nervous system is admitted in many of the examples, the toxins probably producing the eruptions in many cases through their action on the vasomotor nerves, both central and peripheral. Nerve shocks are also sometimes the immediate cause of eruptions, but while this influence is important it is in great part indirect, except in such a disease as herpes zoster, which may be the direct outcome of either central or peripheral nerve lesions, though those due to inflammation of the nerve ganglion of the posterior root are more common than those from lesions of other parts of the nervous system. Apart from these, the diversity of the skin lesions in apparently similar nerve lesions suggests that the nervous influence is indirect, and requires some other exciting factor. Further, in most cases of lesions of the nervous system there are no skin lesions at all. At the same time, if all innervation be abolished no inflammation can occur. If cerebral influence only be abolished, the eruption is violent and severe; in partial vasomotor injury the eruption is slight and perhaps fugacious, while in partial cerebral or spinal damage the eruption will probably develop at the defectively innervated part first and most severely. The protective influence of the nervous system is exemplified in the liability to bullæ, perforating ulcer, and other lesions in the late stage of the nerve form of leprosy.

The influence of the nervous system on the distribution of eruptions is much greater, and many examples of such influence are available where the eruption was in the domain of one or more nerves, both in congenital lesions, such as ichthyosis-hystrix, nævi, &c., as well as in dermatitis, as in zoster, and in some cases of eczema, lichen planus, &c.

Still more important is the distribution in vasomotor areas, of which the bust and arm distribution of xeroderma pigmentosa is a good example, whence the advantage of counter-irritation in recurrent inflammations over the governing centres such as the cervical or lumbar enlargement.

In respect of pregnancy as a cause of eruptions, chief stress must be laid on the variety of dermatitis herpetiformis known as "herpes gestationis"; in some cases it constitutes the earliest sign of pregnancy, and after parturition there is frequently an exacerbation of explosive violence, followed by a gradual decline in the severity of the successive outbreaks, and finally, complete subsidence in the majority of cases.

The influence of seasons is shown as regards erythema multiforme, psoriasis, urticaria, and prurigo, and we meet with recurring summer and winter eruptions which begin in early childhood and persist to adult age, and then usually subside. With regard to the type called by Hutchinson "summer prurigo," a precisely similar eruption may occur in winter, but much more rarely, and in these cases ointments always increase the irritation, while astringent lotions, especially those of the organic silver salts, give most relief. While the general behaviour as regards exciting

causes, evolution, duration, and eventual subsidence is very similar, the morphology of these eruptions varies considerably, and they may be papulo-erythematous, papulo-vesicular, and vesiculo-pustular, though pale red conical papules, with or without a little clear fluid at the apex, are the most common, while in hydroa aestivalis, with its sub-variety, vacciniformis, the lesions are scar-leaving bullæ, which lead to great disfigurement and even mutilation, which simulates lupus vulgaris. The whole class may be regarded as angioneuroses with a congenital vulnerability of the skin something like that of epidermolysis bullosa.

Drug eruptions need only be discussed as regards bromide and iodide eruptions, which are the only distinctive ones, other drug eruptions not being recognised as such unless it is known that one of the possibly eruption-exciting drugs has been given. Bromide and iodide agminated eruptions can always be recognised, and while in infants they may occur from very small doses, even through suckling when the mother is taking the drug, in adults if an eruption occurs from a moderate dose, it is an indication of defective elimination due to either heart or kidney disease or both. Both bromide and iodide eruptions often attack scar tissue, and their diagnosis is missed sometimes because they often do not come out one or two weeks or more after the drugs have been stopped. This is explained by their having a diuretic action which ceases soon after the drug is stopped, and then the salt which is left in the tissues produces the eruption.

The influence of gout has been left to the last because there is no need to emphasise a factor which in the past has been overrated both by the doctor and the public. While no one can doubt that gout is a strongly predisposing cause of inflammation of the skin, it is not possible to diagnose gout by the skin lesion alone; moreover, experience often shows that frequently when we have done our best to neutralise the supposed uric acid element by alkalies and other antigouty remedies, the eruption is still too often recalcitrant, and in a large proportion of cases it is probably only another example of toxin absorption from the intestine. The tendency of gouty persons to chronic intestinal catarrh, and the readiness with which intestinal fermentation is set up, being the real factors requiring attention, intestinal disinfectants of the salol class, and a dietary which is not likely to disagree and produce further intestinal fermentation constitute the real indications.

Clinical Records.

CASE OF PRIMARY CANCER OF LIVER IN A GIRL, ÆT. 21.

By W. J. THOMPSON, M.D. Dub., F.R.C.P.,
Physician to Jervis Street Hospital.

CANCER of the liver is not by any means an uncommon disease, but primary or secondary cancer of the liver, at the age of 21 years, is rarely ever met with, and so I considered this case of sufficient interest to bring before the Pathological Section. Murchison, in his historic record of cases, mentions only two of primary cancer, one Æt. 42 and the other Æt. 50. He also records a case in a patient, Æt. 24, who had well-marked pyrexia, but at the autopsy there was a cancerous mass found in the neighbourhood of the left kidney which extended down along the vessels to the testicle. He states that when cancer first commences in the liver, other parts, notably the mediastinal, inguinal and cervical glands and the lungs, are apt to

become secondarily affected. Coming to more recent times, Dr. Hale White, in the chapter on "Tumours of the Liver" in Professor Allbutt's "System of Medicine," deals with statistics relative to cancer of the liver very fully. He states that at Guy's Hospital during the nine years 1885 to 1893, out of about 4,200 post-mortems secondary cancer of the liver was found in 136 cases, 126 of which were carcinomatous. He further states that during twenty-four years, from 1870 to 1893, out of about 11,500 post-mortems made at the same hospital only eleven cases of primary cancer were discovered, or about 10 per cent. The proportion of primary to secondary cancer is about one to twenty-five. The age of the youngest case recorded was 23. He also states that out of seven cases recorded in the Pathological Society of London during a period of twenty sessions the youngest case reported was 33 years. He made a remarkably interesting statement when he said that in none of the recorded cases of primary cancer was there any family history of the disease, also that the greater number of cases occurred in men.

Mary R., Æt. 21, was admitted to Jervis Street Hospital on October 31st, 1902. Her family history, which was reliable, was good, none of her people having died from cancer or tuberculous disease, nor was there any history of lunacy in the family. She had always been strong and healthy and until admission was employed in a bottling store in a distillery. About four months previous to this she first commenced to complain of gastric disturbance, uncomfortable feeling after food, vague epigastric pains, vomiting, and on one or two occasions she stated she vomited blood. Her stomach trouble becoming worse, and feeling unable to follow her occupation—in which she had a good deal of stooping and leaning forward to do—she was sent into hospital as a case of probable gastric ulcer.

On admission the liver was found to be uniformly enlarged, smooth on the surface, no pain on deep pressure. It extended about one inch below the costal cartilage and almost filled the epigastric region. The abdomen was not distended, nor could any hard nodules, or tenderness, or fluid be detected in it. The patient could not point to any localised painful spot in the region of the stomach. The tongue was coated, pulse, heart sounds, and temperature normal. The amount of urine secreted each day averaged forty ounces. It was normal in colour, free from albumin or sugar, but contained urates. The uterine functions were normal. The bowels were not constipated, and the motions did not show any liver disturbances. Professor McWeeny examined the blood and found it practically normal, with very slight polynuclear leucocytosis. It was quite evident the gastric disturbance was due to pressure, and this remained her most distressing symptom all through her illness.

After admission the liver enlarged rapidly, but remained free from pain. She complained of a dragging sensation in her right side. She was unable to take and retain nourishment, and she lost flesh rapidly. Six weeks after admission ascites appeared and a couple of weeks after this slight jaundice supervened, which, however, never became well marked, except for the weight and pressure of the enormously enlarged liver. She never complained of actual pain in the liver, nor could it be detected on pressure. About the same time the ascites appeared slight nodules were first able to be felt, and these in a short time were well marked. Before death, which occurred on January 18th, 1903, the liver extended as far down as the umbilicus, and when removed from the body weighed 197 ounces. The temperature remained normal until ten days before death, when it fluctuated very much, sometimes going up as high as 103°. Her illness lasted altogether about seven months. At the autopsy the abdomen was filled with dark-coloured fluid; there were no glands enlarged, the lungs, kidneys and spleen appeared normal, the ovaries were slightly enlarged, the left one more so than the right. I greatly regret they were not kept for Professor McWeeny, as I had intended.

Looking at the case from a clinical standpoint, the prominent interesting facts are: (1) Age of patient, (2) absence of any family history, (3) painless character of the enlarged liver, (4) lateness at which the ascites, the nodules, and the jaundice appeared.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND
SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, FEBRUARY 27TH, 1903.

The President—E. J. McWEENEY, M.D., in the Chair.
CANCER OF OVARY.

DR. JELLETT showed with Professor O'SULLIVAN a specimen of double adeno-carcinoma of the ovary. He said that the specimen had been removed from a patient, aged about forty. She had been in comparatively good health until December 1901, then her menstruation ceased and she believed herself to be pregnant. In the following June she noticed a swelling in the left iliac fossa, and at the same time suffered from severe attacks of pain. The tumours were removed in September. At the operation there was no apparent involvement of the pedicle, nor noticeable enlarged glands. The subsequent history of the case was difficult to obtain. He saw the patient two months after the operation, and there was then a small irregular mass in the bottom of Douglas's pouch. This may have been a malignant extension or a faecal collection, but as the patient refused further treatment it was impossible to definitely determine.

Professor O'SULLIVAN described the solid ovarian tumours as being to the *naked eye* very much alike and about the size of a clenched fist, with surface smooth, uneven with large projections. The tumours were enclosed in what appeared to be a dense fibrous capsule, but proved to be condensed and flattened stroma of the ovary. On section the greater part of the growth was white, resembling ovarian tissue in its markings, but firmer. In one place there was a large blood extravasation. Through the white substance were minute cavities, pin-head and smaller, and occasionally much larger ones—cysts. The largest of these was filled with a papillary growth and contained a glairy fluid. On examination under the microscope the tumour was found to consist of a stroma resembling the ovarian stroma cells, with spindle and rod-shaped nuclei, and a very small quantity of intercellular substance. The blood vessels which ran in the stroma were well formed and fairly thick walled; both arteries and veins could be made out. Embedded in this stroma were epithelial structures varying in appearance in different parts. In some places were cysts lined with a high calcium epithelium, ranging in size from a pea down. They contained a granular material with a few swollen cells; these structures were found down to a size when the single layer of epithelium filled up the whole lumen. The largest of these cysts contained papillary growths. Through the rest of the tumour were solid masses of pleomorphic epithelium laying in the stroma and communicating with each other forming a network of epithelial strands about equal to the stroma in bulk, and traversing it in all directions. The only solid ovarian tumour which bears any resemblance to this of which I have seen an account is a tumour described by Von Kahliden (*Cent. f. Path.*). In this growth part was composed of small cysts, part of thick columns of cells. These two were separated by a fibrous partition. He distinguishes them as the cancerous changed portions and regards the growth as derived from the follicular epithelium. Here the two forms of growth appear to be intermixed. Both can be seen in the same microscopic field.

The PRESIDENT said that the case was undoubtedly one of true carcinoma of the ovary. The bilateral character of the affection was typical. The relatively slow development of metastatic infection was likewise often observed in ovarian cancer. He had himself

observed three cases in the last one of which the microscopic appearances were very similar to those seen in this case, save that the adenomatous element was less pronounced. Learning from the writers that recorded cases of ovarian cancer are few in English literature, he proposed to publish the notes of those he had observed.

DR. EARL said he had examined several cases of cancer of the ovary, probably some eight or more. Both ovaries were affected in each case. In two cases the cancer was in an early stage of mucoid degeneration, and in one case at least there were secondary growths in the peritoneum and liver.

DR. JELLETT said that he did not consider ovarian cancer to be very rare. He had operated on one other case, and had seen at least four in the Rotunda Hospital. As to the question of malignancy, one at least of these ran a most malignant course. Metastases occurred in the retro-peritoneal glands, and ate through the spinal column, death resulting within three months of the operation.

ABNORMAL DEPOSIT IN JOINTS.

Professor E. H. BENNETT showed a series of joints marked by the deposit of a white material closely resembling the urate of soda seen in true gout. The deposit was present in the hips, shoulders, sternoclavicular joints, and was absent from the more distal joints of the limbs. The deposit was shown to be calcium carbonate. He also exhibited a water colour drawing showing the appearance of the joints affected by this disease, while unaffected by this disease of formation and of spirit used to preserve the tissues.

The PRESIDENT asked what distinction Professor Bennett drew between the condition he now demonstrated and calcification, such as occurs in costal cartilages and many morbid tissues.

Drs. TRAVERS SMITH and KNOTT spoke.

Professor BENNETT, in reply, pointed out that in this case the calcium carbonate occurred in the form of small crystals.

DR. PARSONS and Professor O'SULLIVAN exhibited a sarcoma of the duodenum with microscopical sections.

The PRESIDENT considered it to be in all probability a round-cell sarcoma, but could not explain the hybrid matter referred to by Prof. O'Sullivan. He asked how it behaved to the Van Gilson triple stain? He thought the case ought to be submitted to the Committee of Reference.

FRACTURE OF THE ASTRAGALUS.

Professor E. H. BENNETT showed an united fracture of the astragalus. The fracture had united without deformity by bone. There was no other fracture either in the bones of the foot or of the leg or thigh. The specimen was found in dissection, and was without history.

Mr. THOMPSON read a case of

PRIMARY CANCER OF LIVER IN A GIRL, ÆT. 21.

which will be found under the head of "Clinical Records."

Professor McWEENEY said the liver is much enlarged. its surface is studded with secondary nodules, some of these umbilicated. The colour is dull red with a greenish tinge. The nodules, viewed from without, are white. On section, the primary mass was found occupying the centre of the right lobe. It was as large as the closed fist and harder than the secondary knots. On cutting into the specimen a most remarkable change took place in its colour, *most of the secondary knots assuming a brilliant grass-green hue on contact with the air.* This green hue subsequently extended to the liver parenchyma after the spectroscope had been placed in formation. Spectroscopic and other tests showed it to be due to oxidised bile-pigment. The cancer was composed of very large epithelial cells closely resembling liver-cells, but differently arranged. Many of them were crammed with globules of green pigment, and here and there presented an attempt at tubular arrangement, the lumen being filled with green matter. It was evident that the cancerous degeneration had not robbed the tumour-cells of their function, and that

they had continued to secrete bile, though several generations removed from normal liver cells. The bile-pigment so secreted, finding no outlet, was stored up in the cells, and revealed its presence by the green hue at once assumed on section by the cancer tissue.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.
MEETING HELD MARCH 4TH, 1903.

Dr. UNDERHILL, Vice-President, in the Chair.

DR. CHALMERS WATSON showed a case of *verrucae planae juveniles* (with photographs to illustrate treatment).

Dr. F. D. BOYD showed (1) a case of localised syphilitic meningo-myelitis, with anaesthesia of one-half of the scrotum and penis; and (2) a case of tabes with well-marked ataxia, in which there was, in addition, lesion of many of the cranial nerves, showing itself by ophthalmoplegia, defective movements of the tongue, alteration in speech, paralysis of the vocal cords, and laryngeal crises. The lesion at the base of the brain was either a syphilitic meningitis or a vascular change—probably the latter, since antisyphilitic treatment had not caused any amelioration of the symptoms.

Dr. GEORGE GILSON showed (1) a child with combined obstruction and incompetence of both aortic and pulmonary orifices. The pulmonary incompetence might be due either to a giving way of the valve from the increased pressure on the pulmonary artery, or, more probably, to endocarditis. (2) A man with Raynaud's disease showing some interesting features. The patient had a dilated stomach, and both kidneys were movable; a trace of scleroderma of the hands was present, and the ears showed signs of past attacks of local gangrene. The chief feature of interest, however, was the condition of the veins over the surface of the body, which passed into a condition of spasm, and stood out like whipcord (they could be felt in the dark when the hand was passed over the skin) on exposure to cold. Warmth relaxed the spasm, which he conjectured to be the cause of the Raynaud's disease in this case, as spasm of the arterioles was in others.

Dr. JOHN THOMSON showed a case of "spasmodic stricture of the oesophagus" in a boy, *æt.* 9. Ever since the child was a year old he had had difficulty in swallowing solids, and for about the same time he had been liable to attacks of vomiting lasting for several days at a time. He had just recovered from one of these attacks, which had taken place during his stay in hospital. While this lasted little or no food seemed to enter the stomach; a few ounces of milk could be swallowed, but after a short interval it was regurgitated with a quantity of mucus, and showing no sign of having passed beyond the oesophagus. The attack passed off suddenly, the patient saying that "he felt something go down." During the attack not even the smallest sized stomach tube could be passed into the stomach; after it a fairly large one entered without much difficulty. It was clear that a certain amount of dilatation of the oesophagus was present, and also that a condition of spasm existed. Whether or not there was an organic narrowing was not easily to be determined.

Mr. ALEXIS THOMSON showed (1) a case of "infantile paralysis of the lower extremity" treated by arthrodesis of the knee and Pirojoff's amputation at the ankle eight years ago, and (2) a case of Dupuytren's contraction of the palmar fascia for comparison of the result of excision of the fascia with that of Adam's operation. The latter seemed to have given the better result.

Mr. STILES showed (1) a child, *æt.* 2, who was undergoing the first stage (extreme abduction of the legs) of the treatment of double congenital dislocation of the hip. (2) An infant, after excision of a sub-occipital meningocele complicated by hydrocephalus. The meningocele was about the size of a lemon, and extended from the occipital protuberance to the foramen magnum. Fluctuation between it and the bulged anterior fontanelle could easily be made out.

Dr. R. A. LUNDIE showed a girl, *æt.* 10, with dwarfing of the metacarpal bone of the ring finger, due, as the

skigram showed, to premature synostosis of the growing end of the bone.

Dr. WILLIAM RUSSELL read a paper on

"HYPERCHLORHYDRIA, OR GASTRIC HYPERACIDITY: ITS NATURE AND RELATION TO DYSPEPSIA."

It was formerly thought, the speaker said, that most cases of indigestion were due to improper fermentation in the stomach, but it was now known that in many instances acid dyspepsia was caused by an excessive secretion of hydrochloric acid, and if this continued over long periods, the inevitable result was gastric catarrh and dilatation. Hyperchlorhydria was a common form of dyspepsia, about 25 per cent. of all hospital cases of that disease coming under this head. It was usually possible to make the diagnosis by the symptoms alone, but to do so the examination of the patient must proceed along orderly and systematic lines. The speaker then referred to the method of examination he employed, which amounted to beginning the questioning with inquiry as to how the patient felt on rising in the morning, of what his first meal consisted, when the dyspeptic symptoms began, what the effect of subsequent meals on them was, and so on. Patients with hyperchlorhydria feel well on waking in the morning, and the first symptoms appear in the forenoon, one, two, or two and a half hours after breakfast. These last for an hour or two, and then may pass off, or, if they continue till the midday meal, that relieves them temporarily. The pain is severe or slight, and is referred to the epigastrium, back, or shoulder-blade. There is sometimes a little superficial abdominal tenderness. Flatulence and eructations of acid fluid are common, the latter giving temporary relief. Constipation or imperfect evacuation of the bowels is common, and paroxysmal pyrosis (abortive vomiting, according to Roberts) is occasionally met with. There is often great physical and mental languor during an attack of hyperchlorhydria. The explanation of the symptoms was as follows:—The starchy foods are rendered more digestible by cooking, and the longer the heating is continued the more easily digested do they become. Part of their conversion is accomplished in the mouth by the saliva, and their further conversion in the stomach by the continued action of the swallower. Saliva is checked as soon as the gastric contents become acid, when the digestion of proteids begins. Whenever for any reason an excessive secretion of hydrochloric acid takes place, the digestion of the proteids goes on normally, but that of the starches does not; these, along with the fats, are retained in the stomach and keep up the hyperacid gastric secretion, which, however, they cannot neutralise. The stomach wash, or vomited matters, of sufferers from acid dyspepsia invariably shows excess of hydrochloric acid, the presence of undigested starch, and, which was not sufficiently recognised, much fat. The less stimulating and more easily digested the proteid taken, the less secretion of hyperacid gastric juice evoked, and hence the less discomfort caused. With regard to the etiology, the speaker did not believe that acid dyspepsia was of nervous origin, and thought that such terms as "gastralgia," "nervous dyspepsia," were entirely misleading. Some people were apparently liable to secrete too much gastric juice, especially those of a rheumatic or gouty diathesis—they had, indeed, to do with a faulty metabolism which might be described as an "acid dyscrasia." Against the idea that the condition was nervous were the relief got by emptying the stomach, by the administration of alkalies and by dilution. The treatment in slight cases with constipation often resolved itself into relieving that symptom; alkalies should be given an hour or two before food, or when the symptoms began, and acids should be avoided. During the attack starchy food should be dispensed with to a greater or less degree. In the worst cases the acid residuum should be removed by irrigation of the stomach. In dieting such cases, so as to avoid recurrence, the chief objects were to reduce the proteid taken to the physiological minimum, and to render the starch easy of digestion by thorough cooking, &c.

Considerable discussion followed Dr. Russell's paper, in which Drs. George Gilson, Affleck, Ritchie, Underhill, Boyd, Gulland, Hunter, and Stiles took part. Many of the speakers alluded to the undoubtedly nervous element often seen in these cases, as, for example, that sufferers were most liable to attack when worried or exhausted, while among other points raised were the importance of constitutional disorders and diseases of the blood as factors in the cause of the condition, the occurrence of acid dyspepsia, due not to pre-hydrochloric acid but to acid phosphates, the difficulty of diagnosis between hyperchlorhydria and gastric ulcer, and the possibility of the former, apart from the latter causing dilatation of the stomach, the importance of the muscular function of the stomach in dyspepsia, and, as regards the treatment, the great importance of rest in many cases.

Mr. ROBERT PURVES read a paper on
"HAND DISINFECTION."

He first pointed out the importance of protecting the hands at non-operating times from casual and general infection, and recalled the fact that this principle of endeavouring to keep the hands germ free had been repeatedly urged by Miculicz and Kocher. He considered that, although one might not be able to carry into effect Kocher's suggestion of always wearing gloves except when operating, a very considerable degree of "germ-poverty" could be attained by (1) protecting the hands from ordinary dirt, cuts, &c., by wearing gloves constantly when out of doors; (2) always washing the hands after examining cases; (3) keeping the nails very short; (4) never touching anything of an infective nature with the bare hand, using rubber gloves to operate on and dress septic wounds, and to examine pathological specimens, and employing finger stalls when making rectal, oral, or vaginal examinations. That it was possible to obtain a germ-free hand he considered evident, not only from Krönig and Reincke's observations, who found such to occur in time if the hands were not re-infected, but also from his own observations on the hands of washerwomen, from which, after five hours' washing, no cocci could be obtained. He emphasised the value of prolonged preliminary cleansing with soap and water, for at least ten minutes, and suggested a system for adoption in the use of the nail brush. He considered a time recorder an advantage, and pointed out the tendency for the thumbs and right hand to escape with a less thorough cleansing. In his series of sixty experiments on the hands of washerwomen he found that after one and a half hour's washing cocci were found in only 45 per cent., 36.4 per cent. of these being *aures*, and with longer washing a further reduction occurred until after five hours no cocci were found. He believed that the success met with by any subsequent disinfection process depended more on the thoroughness with which the details were carried out, particularly by nurses and assistants, than on the selection of any one particular method; and, further, that only under the most favourable circumstances could one adopt a technique in which active disinfectants were dispensed with. Mr. Purves had found that the substitution of methylated spirit for alcohol in Miculicz's spirit soap, to reduce the cost, yielded good results, but the mixture had had to be abandoned on account of its irritating effect on the skin. He strongly advocated the use of thread gloves, especially during the stage of ligaturing and suturing, to prevent infection of the ligature by the fingers, and discussed the details of the uses of gloves. Finally, he attached considerable importance to control cultures from the hands and operation area, and showed a tabulated series of his own observations.

The paper was discussed by Drs. Allan Jamieson, Lundie, and Haig Ferguson, and by Mr. Stiles, Mr. Cathcart, and Mr. Alexis Thomson.

The Annual Congress of the Royal Institute of Public Health will be held from July 15th to July 21st, 1903, in Liverpool.

[LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD FEBRUARY 26TH, 1903.

RUSHTON PARKER, Esq., B.S., F.R.C.S., President,
in the Chair.

DR. GORDON LITTLE read a paper upon "Moorish Spain."

Dr. NATHAN RAW read a paper upon—

HUMAN AND BOVINE TUBERCULOSIS,

an abstract of which will be found elsewhere.

The PRESIDENT said that opinions formed upon a question of this kind are based partly upon clinical impressions and partly upon scientific considerations. He thought that we were in need of pure science to control the impressions we were tempted to rely upon. He had himself not gone much into the intimate pathology of the question, having originally operated for the purpose of removing the local disease. An experience of thirty years had satisfied him as to the correctness of this point of view; he had only met with phthisis pulmonalis four times out of about three hundred patients.

Dr. CARTER recognised the ingenuity of Dr. Raw's suggestion of two different diseases, but considered the view that true human tuberculosis cannot be communicated by bovine tuberculosis was too absolute, and was disproved by recorded facts. If the words had been "is not generally communicated" he, like every one else, must have assented. It was too early to dogmatise. He thought the difference of results probably depended on difference of soil, the seeds being identical. Ravenel, in the very paper quoted by Dr. Raw, while admitting the general resistance in both directions, *i.e.*, from man to cattle, and from cattle to man, gives not a few examples of deviation. Thus he injected tuberculous sputum intraperitoneally into four calves, of which three soon presented evidence of infection with true general tuberculosis. Again, the same observer points out that bovine tubercle accidentally planted in human skin develops effects entirely indistinguishable from true human tuberculosis; and one case at least in the contrary direction has been related when a child was bitten on the lower eyelid by a dog which had just eaten the tuberculous placenta of a cow. All the after effects were those of a disease indistinguishable from true human tuberculosis. Then we are probably all familiar with the numerous successful inoculations by Arloing of human tubercle into cattle. These and many similar cases must make us cautious in too hastily accepting a theory, however fascinating—as this theory certainly is—till the proof has been made absolute.

Dr. CATON admitted that apparently two forms or types of tuberculosis occur in the human subject:—(1) Pulmonary phthisis, (2) tubercle of glands, bones, and nervous organs, and that usually the course and termination of the two types presented marked differences. This fact supported Dr. Raw's interesting generalisation. Dr. Caton narrated instances in which the second form of tuberculosis had followed the use by children of raw milk from tuberculous cows. He had been much impressed by the large proportion of cases of bovine tuberculosis which he had himself observed when visiting rural districts of England and Scotland, and by the disregard of the disease manifested by the dairy farmer. Dr. Raw's theory, if fully demonstrated, would have most important practical results.

Dr. ALEXANDER said he had had sixty-two cases in the last three years, and out of 885 babies in the Liverpool workhouse hospital eighty-two were diagnosed as marasmus or tabes mesenterica. A good many cases of tabes mesenterica recover completely, so that it is probable in many cases the disease is not tuberculous. The children who suffer from this disease belong to the lowest class of society, and their diet leaves much to be desired. They live on small quantities of milk bought from a low milkshop, which is used without being sterilised. Many of them suffer from attacks of intestinal and gastric catarrh through improper quantity

or quality of food, and these attacks produce enlargement of the glands just the same way as eruptions of the scalp and discharge from the ear produce enlarged glands in the neck. If the intestinal condition recovers, the glands lessen in size, but if the condition is prolonged for a sufficient time the tuberculous microbe gains admittance, and we have tuberculous disease just as happens in the neck or glands elsewhere. If what Dr. Raw says is true, we shall have to go back to the sterilisation of milk. He hoped that this whole subject would be rapidly investigated, as it cannot, without harm resulting, long remain in such a condition of doubt and indecision.

Dr. GRUNBAUM agreed with Dr. Raw that *tabes mesenterica* was due in many cases to milk carrying bovine tubercle bacilli. Experiments on anthropoid apes tended to confirm this view. Dr. Raw's isolation of the bovine bacillus from a mesenteric gland was the first published confirmation of Ravenel's results in the same direction. But that was no reason for considering the disease produced, separate and distinct. For the following reasons it seemed probable that the disease was one and the same, whatever the source of the bacillus, although undoubtedly more virulent when of bovine origin. The lesions produced by the inoculation of either form were practically the same, and Perlsucht could not be caused even by inoculating cattle with bovine bacilli; a bacillus with human morphology might have almost bovine virulence, as shown by Ravenel's second case, and cattle reacted to tuberculin of human origin.

Sir WM. BANKS said that if Dr. Raw's thesis were true, then persons dying of phthisis need not specially show any signs of having been afflicted during childhood in any marked degree with *tabes mesenterica*, diseased cervical glands, or articular troubles. This was what Dr. Raw had endeavoured to prove by statistics. It was the side to be approached by the physician, and the great workhouse hospitals would be able to supply most valuable evidence on this point. It was his conviction that children who suffered from glandular and articular diseases did not suffer in later life in any marked degree from phthisis. He therefore was opposed to the tremendous and sometimes dangerous dissections of the neck practised by some surgeons. These children died from exhaustion and waxy disease when they did succumb. For himself he found a difficulty in looking upon bovine and human tuberculosis as two absolutely distinct diseases. He would prefer to call them variants of the same disease affecting each their own localities. The seeds of the various kinds of cabbage did not show notable differences of appearance, but the wild progenitors of the vegetable flourished in the sea sand while the big cultivated cabbage would only grow on good land. Soil in this question probably had much to be reckoned with.

Dr. MACALISTER, while expressing his appreciation of Dr. Raw's interesting and suggestive paper, reminded the meeting that new ideas of the kind had to be received in a spirit of scepticism. On the occasion of Professor Koch's startling address in 1901, he had been much struck by the caution which had characterised the speeches of Lord Lister, Professor Nocard, and Professor Sims Woodhead, and the latter address of Professor John MacFadyean, all of which had indicated that further observations would be required before Professor Koch's pronouncement could be unreservedly accepted, and while regarding the edict of the great bacteriologist with every respect, he (Dr. Macalister) had preferred since then, if any mistake were made, to make it on the side of safety, and not to relax the precautions which had always been enforced in his own house respecting the sterilisation of milk, and this notwithstanding the fact that he has some scruples about boiling milk for children on account of its possible destructive action upon the anti-scorbutic properties of that food. He referred to 109 fatal cases of tuberculosis in children, in which careful post-mortem examinations had been made (Pendlebury Abstracts) and in no less than eighty-four of these there was involvement of the mesenteric glands, but it could not

be said of all of them that infection had taken place through the alimentary canal, because manifestly in a certain proportion the mesenteric infection was of later date than the pulmonary; in almost every case the tuberculosis was general. Dr. Macalister thought that it seemed highly probable that however introduced into the system, a large number of children evidently constituted a suitable soil for the growth of tubercle, but it appeared to him that to attempt to differentiate the tuberculosis of childhood into two different diseases was extremely difficult. He referred to the explanation which had been adduced concerning the relative immunity of cattle to human tuberculosis, being possibly due to the passing of the bovine organisms through the human subject. In the course of his remarks Dr. Macalister also referred to cases of pulmonary phthisis and to abdominal tuberculosis existing in the same house, and he considered also that careful investigation would require to be made concerning the feeding of infants, as to whether all cases of primary mesenteric diseases were hand-fed. He had an impression, although he could not specify an instance from memory, that he had seen tuberculosis arise in breast-fed infants. His general conclusion with reference to the origin of the disease in childhood as compared with the adult tuberculosis being that there was a distinction without a difference.

Dr. R. J. M. BUCHANAN stated that although Dr. Raw's communication was novel and startling at the outset, on careful consideration it offered nothing more than suggestion; it established nothing, and proved nothing. He contended that tubercle bacilli *per se* could not be classified by clinical methods, as so much depended not only on general "soil," but local "soil," in respect of different organs, this meaning a low potential, want of resistance or vulnerability. Further, that account must be taken of the accessibility of entrance of the organism to the body, such being influenced by a variety of circumstances; for instance, in children fed on cow's milk the alimentary canal offered distinct points of vantage to the invasion of bacilli. The lungs are peculiar, and subject to many dangers and vicissitudes from their complicated structure, their incessant movement, and their accessibility. Dr. Buchanan held that the clinical manifestations of tuberculosis depended upon the organ attacked, and offered no means of distinguishing between so-called bovine and human tubercle bacilli. He asked Dr. Raw what evidence he had to offer in proof of the tuberculous nature of his cases of *tabes mesenterica*, and especially of their being due solely to bovine tubercle. He emphasised as a significant and important factor in the identity of bovine and human tubercle that in cases of pulmonary and other local infection both responded in the same way to the tuberculin test. He regretted that Dr. Raw was unable to exhibit the cultivations he had made from *tabes mesenterica* and strumous knee-joint, and also phthisical sputum, upon which he had based such a large share of his conclusions.

Dr. J. HILL ABRAM said he had never been convinced of the soundness of Koch's position. He would like to draw attention to the following point: Koch's great dividing characteristic between bovine and human tubercle was the non-communicability of the two organisms to human and bovine respectively, *i.e.*, human to cow, bovine to man. Ravenel's, and now Dr. Raw's, cases shattered Koch's position, and restored the unity of tubercle.

Drs. Permewan, Gullan, Logan, Barr and Mr. E. G. Hamilton spoke, and Dr. RAW replied.

ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST,
THURSDAY, MARCH 5TH, 1903.

The President, Dr. JOHN CAMPBELL, F.R.C.S., in the
Chair.

Dr. CECIL SHAW showed a case for diagnosis, a woman, *æt.* 53, with marked proptosis of the left eye, slowly increasing for at least eighteen months. There

were no other symptoms, no pain, normal vision, and normal ophthalmoscopic appearances. There was no pulsation, and on pressure the eyes seemed to rest on a very firm bed. Lately there seemed to be slight general swelling of the whole temporal region on that side. The probability seems to be that it is a slow-growing tumour in the orbit.

Dr. J. R. DAVISON showed a patient with cancer of the breast, under treatment with the X-rays. There was distinct improvement in her condition since treatment began.

Dr. CECIL SHAW read notes on "Some Recent Advances in Ocular Therapeutics," which we hope to publish in our next issue.

Dr. R. W. LESLIE read notes on "The Use of Cacodylate of Sodium," giving the history of eight cases in which he had used it—seven of phthisis and one of pernicious anæmia. Though most of his cases were in the last stage of phthisis, and not very hopeful for treatment, he was satisfied that the drug had a decidedly beneficial effect, and he meant to persevere in its use.

Sir Wm. Whitla, Drs. McKisack, Stevenson, Austin, McQuitty, and Walton Browne discussed the subject.

Dr. W. D. DUNNAN read a paper on

TWO CASES OF ACUTE INTUSSUSCEPTION.

Both cases he had sent to the Belfast Children's Hospital, where Mr. Kirk had operated on them. In one in which the signs were clear and the diagnosis certain, the result was fatal; but in the other, which was operated on early, while diagnosis was still uncertain, the child recovered. Mr. Kirk described the operations, and emphasised the uselessness of attempts at reduction.

Dr. LESLIE described two cases in which he had operated in the Ulster Hospital for Children and Women, one successful and the other dying of bronchitis some days after operation. He agreed with Mr. Kirk on the necessity for early operation.

Dr. JOSEPH MARTIN read short notes on a case of pneumothorax.

Dr. J. R. DAVISON gave an account of a case of "Plastic Bronchitis" and its successful treatment. He had used anti-diphtheritic serum with complete success.

Sir Wm. Whitla and Dr. Thos. Houston discussed the case, the latter suggesting that the effect of the serum might be due to the blood changes which it often caused, as seen by the rash that sometimes follows its use.

On the motion of Dr. McQUITTY, a vote of sympathy with the widow of the late Dr. Samuel Alexander, a Fellow of the Society, was passed.

At this meeting Dr. C. K. Darnell (Bangor) and Dr. R. J. Munn (Belfast) were elected Fellows of the Society.

CORK MEDICAL AND SURGICAL SOCIETY MEETING HELD WEDNESDAY, FEBRUARY 25TH, 1903.

Dr. P. T. O'SULLIVAN, President, in the Chair.

DR. H. R. TOWNSEND showed a young woman, æt. 28, on whom he had performed

DOYEN'S OPERATION

of removal of uterus, ovaries, and Fallopian tubes for double pyosalpinx. The patient had been ill for nearly twelve months, complaining of abdominal pain and tenderness, night sweats, and intermittent pyrexia. A tumour could be felt in Douglas' pouch per rectum. The uterus was enlarged and was consequently removed with the other structures. The peritoneum was so much affected that it was impossible to stitch it, and the wound was drained per vaginam. Two days later the temperature rose, the wound was reopened, and a large quantity of pus washed out from the pelvic cavity. The same procedure had to be adopted five days afterwards, and a second gauze drain was inserted abdominally. The patient made a good recovery from this point, and had since been free from all pain and other symptoms.

Dr. C. YELVERTON PEARSON showed a skiagram of a halfpenny in the œsophagus of a child, æt. 5, which he

subsequently removed by a coin-catcher. He also showed a skiagram of a case of Brodie's abscess, which he had injected with iodoform wax. Dr. Pearson also showed a tumour of the pylorus which he had removed by pylorotomy from a man, æt. 60. He had not yet examined the specimen, but he had little doubt from its appearance, and from the symptoms of the case, that it was a cylindrical epithelioma. Unfortunately the patient died suddenly four days after the operation from cardiac failure.

Dr. J. COTTER read notes of a case of

HEMICHOREA COMPLICATING BURNS.

The patient was a girl, æt. 7, who had sustained rather extensive burns of the third degree on the right arm and right side of the chest and abdomen. About a week afterwards she suddenly developed chorea, affecting the left arm and leg. It yielded to the usual treatment, but the pathology of the affection in this case afforded much ground for speculation, and its occurrence seemed to favour the embolic theory of the disease.

Dr. E. MAGNER read notes of a case of

HEMIPLEGIA

occurring in a married woman, æt. 28, who was seven months advanced in her fourth pregnancy. It occurred suddenly without loss of consciousness, and was followed after a few days by normal but rather precipitate labour. No cardiac lesion could be discovered after repeated examinations. The patient had regained the use of the affected limbs with the exception of the fixed movements of the fingers. The left side was that affected.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, March 8th, 1903.

HEREDITARY OSSEOUS SYPHILIS.

AT the last meeting of the Académie de Médecine M. Lannelongue read a paper tending to prove that hereditary osseous syphilis presented characters which differed from those of acquired syphilis. In infants (Parrot's disease), as in children, hereditary osseous syphilis shows itself by deformities of the bones of the extremities and of the cranium, incurvations of the tibias and femurs forwards and outwards, incurvation of the bones of the arms backwards, &c. Those lesions were due to neo-formations of the osseous substance and not to softening as was generally supposed.

In adults, on the average æt. 50 (Paget's disease), the syphilis caused similar deformities in the same bones. In all the patients the affection commenced by pain and hyperostosis.

From the foregoing it would result that the disease of Parrot and that of Paget, of which the causes had been up to the present unknown, were due to hereditary syphilis. M. Lanenany said that many of the osseous lesions attributed formerly to leprosy were of heredito-syphilitic origin. As regarded the malady of Paget, the speaker believed that it had nothing in common with syphilis. M. Robin took the same view, saying that the chemical composition of the bones of persons suffering from Paget's disease differed totally from that of syphilitic bone. Besides, the specific treatment had no effect in the malady of Paget.

M. Lannelongue presented two children who suffered from that malady and who were greatly benefited by subcutaneous injections of mercury and the administration of iodide of potassium by the mouth.

CHILDREN AND INSURANCE.

Prof. Budin denounced in indignant terms the traffic of certain insurance companies in the north of France, which for a small sum insure the lives of children, thus encouraging carelessness, criminal neglect, or perhaps worse on the part of the parents. Some children were insured in several companies at the same time. Children

under five years could be insured for the sum of one half-penny, and for which was paid in case of death: under three months, 10frs.; under a year, 20frs.; from one to two years, 30frs.; and so on up to five years, 75frs.

The speaker thought it necessary to bring the matter under the notice of the Academy through which it might attract the attention of the Government. He considered that speedy measures should be taken against those companies, which were for the most part of Belgian origin.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 7th, 1903.

At the Society of the Charité Surgeons Hr. Graf spoke of the

PROGNOSIS OF FRACTURES OF THE SKULL.

The material of the address was furnished by ninety cases treated at the hospital. Seventy-seven of the cases were of men, thirteen being women. Concussion of the brain was present in nearly all the cases after the cessation of the original unconsciousness, there was usually a stage of hallucinations, and after this a subsidence of all symptoms. The total mortality was 28-31 per cent., whilst before this it had generally been somewhat higher. Meningitis was rare, and this the speaker thought due to modern treatment (avoidance of washing out, probing, &c.), or the meningitis might be very late after the injury. In fifteen cases there was mental disturbance, in which alcoholism played a considerable part. Symptoms of clot were rare, they showed themselves as aphasia, paraphasia, convulsions, in part of the Jacksonian type. Disturbance of taste was observed twice, flow of fluid from Steno's duct once associated with facial paralysis. Headache was an almost constant symptom, giddiness was also frequent, especially under certain conditions, as when the head was thrown back. In eleven patients there were labyrinthine symptoms, in seven vomiting, in three mental weakness, the "amnésie rétrograde" of the French. There was also occasionally change of character, partly of an irritable, partly of a melancholy type. In twenty cases there was deafness of a nervous kind. The pathological examinations of the brain had shown various changes, mostly of a diffuse kind.

Hr. König remarked that fractured skull among the working-classes had less serious consequences than formerly. He had had about six cases of fracture of the skull in officers who had been thrown off their horses; they all continued fit for service. Regarding the consequent symptoms on the state of the mind he distinguished two groups from the point of view of prognosis. If the mental weakness came on at once and improved after eight to nine days the prognosis was favourable, but it was bad when it first showed after some three weeks. Only a few of these cases recovered.

Hr. von Haselberg, who had observed the cases from an ophthalmological point of view, said that the late symptoms in the organ of vision were probably due to growth of callus around the optic nerve. Unilateral cataract arose either from direct injury to the lenticular capsule or from disturbance of nutrition in consequence of original papillary stasis, which set up clouding of the nucleus of the lens. Traumatic exophthalmos, numerous paralyses, &c., were also observed.

Hr. Voss, who had observed otologically, said that the most general ear symptoms were difficulty of hearing, noises in the head, headache, and giddiness. A remarkable case was that of a city female school teacher. She heard double sounds, higher in one ear than in the other, and as she was musical, she was naturally disturbed by this,

Hr. Weyner spoke of

TUMOUR-LIKE SYPHILIDE OF THE LIVER,

with special reference to difficulty of diagnosis. There were two cases. In the first there was a movable tumour under the right ribs, which at the operation gave the impression of being malignant. Under energetic treatment by pot. iod. and painting, improvement took place, and a similar improvement followed after a recurrence some time later. In the second case there was hereditary syphilis (keratitis, chorio-retinitis). Some liver nodules were removed which proved to be syphilitic. Here also improvement took place under pot iod. treatment.

Hr. Zim drew attention to Gerhardt's paper on the subject, and described two cases of his own treated in the Bethanien Hospital.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 7th, 1903.

PATERNAL SYPHILITIC TRANSMISSION.

MATZENAUER treated the Gesellschaft to a scientific treatise on the paternal transmission of syphilis which, briefly stated, is that the mother is the principal vehicle of transmission. This theory, he maintains, is proved by other diseases such as typhus, splenic fever, &c. The virus, he contends, is transmitted *intra graviditatem* through the vessels of the chorion, which may be proved by the presence of a local peri-endarteritis with increased epithelial growth. This, he considers, is due to an antecedent infection by the mother. The condition may be localised or diffused, as witnessed in the case of twins where one child and placenta may be found syphilitic, while the other is perfectly healthy. The intensity of the disease in the infant seems to depend upon the period of maternal infection, as the earlier is always the more severe; although the intensity may be less, the virulence of the contagion is in no way reduced. This alternating phenomenon of intensity is an important factor in the transmission of disease, and is met with in others, such as tuberculosis where two sisters of the same mother may be met with, the one being diseased and the other perfectly healthy. He thought he need hardly labour this point, as syphilologists were generally agreed that sound mothers produced sound children though the fathers may be infected, which is against the germinative theory. The proofs adduced were that syphilitic sperm was not infectious, as many syphilitic fathers produced non-syphilitic children if the mother were healthy. This could be demonstrated by widows who by the first husband had infected children while by the second husband, who was quite free from any taint of disease, had also infected children, and *vice versa*. We have also evidence that 30 or 40 per cent. of fathers suffering from tertiary syphilis have produced healthy children. Again, Colles' law favours this theory that a mother of a syphilitic child is immune against syphilis, and although the exceptions observed are that mothers apparently healthy have given birth to syphilitic children it can be proved that the latent force of the mother has produced the disease although herself quite healthy in appearance. Matzenauer's hypothesis is that the paternal transmission of syphilis is a fallacy, and his practical deductions are that a mother of a syphilitic child should be treated with specifics while the father need not. He also contends that a syphilitic father may prevent his wife from being infected or affecting the offspring by specific treatment for several years.

Paltauf, in the discussion that followed, could not understand how the germinative force of transmission could be opposed, as it was hardly possible to conceive an affected ovulum or an infected spermatozoon producing a healthy offspring. He has found by actual ex-

periments with dogs that injections of tuberculous bacilli into the uterus after cohabitation will produce a tuberculous offspring. Immunity of mother and child as a temporary condition is hardly tenable as no proof can be given of its resistance against the primary affection. The teaching of gumma being non-infectious is surely straining argument. It may be true that cheesy masses of tubercle taken from glands may have failed in infecting healthy persons, but it does not follow from this that the morbid mass is non-infectious.

Hochsinger thought that Matzenauer's theory was raised on a frail foundation. He had carefully recorded in conjunction with Kassowitz 250 families with hereditary syphilis, ninety-eight of whom were many years under observation. Seventy-two of the ninety-eight families were infected through the fathers, and in round numbers 276 syphilitic children were born, while none of the mothers, had any symptoms or even suspicion of syphilis. Again he had recorded twenty-six syphilitic mothers and in one of these cases the disease had occurred fourteen times after having been supposed to have been cured. This admitted of an alternating pregnancy, when some of the children, according to Matzenauer's theory, would have been free from the disease, but in no case was there a single exception as all were affected. The same may be said of the twenty-six cases, not one of the children was found to be free of syphilis, and he therefore thought that the alternating theory was a fallacy. Lang said it was true that the female was less in proportion than the male, but he was convinced that closer observation would prove that the virus was conveyed through the germ and not the mother alone.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

EMPHYÆMA OF THE FRONTAL SINUS.—MR. MAYO COLLIER operated on a man, æt. 56, the subject of a discharge of six months' duration proceeding from an opening in the centre and a little below the line of the right eyebrow. Some six months ago the patient had been seized with acute pain in the right frontal region extending into the right eye and root of the nose. The pain was so acute that medical assistance was obtained, and the parts treated with lead and opium and general treatment. The pain somewhat abated, but a considerable swelling took place involving the right eyelid, frontal bone and root of the nose. This was subsequently treated with iodine until, fluctuation being evident, it was incised. A considerable quantity of thick yellow pus was evacuated. On examining with a probe an opening was found in the bone below the margin of the orbit about its centre. The bony orbit was not protruded. The probe passed outwards and backwards for some distance. The case, not progressing satisfactorily, was sent to the hospital, and admitted under the care of Mr. Mayo Collier. Mr. Collier said on the first examination of the man he came to the conclusion that this was a case of emphyæma of the frontal sinus of an acute kind that had opened into the roof of the orbit by perforating the orbital plate of the frontal bone. He pointed out that in more chronic cases the roof of the orbit was thinned and bulged downwards and forwards, displacing the eyeball and the contents of the orbit. In this case no time was allowed for this to take place. The abscess formed rapidly, the process was acute, and perforation took place without the usual bulging. He considered that the unusual course of this case had rendered the diagnosis in the early stages somewhat obscure. The condition of things now, he said, was that a sinus existed in the centre of the right eyebrow involving the tissues of the lid and brow for some distance. He intended to so operate on this case as to get rid of the opening in the eyelid at once

and get the part to heal by first intention, and so avoid an ugly scar. An incision was made from the sinus inwards in the line of the eyebrow as far as the mid-line. The bone was denuded and the glabellum exposed to the extent of a shilling. A trephine of the size of a sixpence was introduced here and a button of bone removed. On this button of bone the mucous lining was found to be diseased and covered with polypoid granulations. The frontal sinus was full of pus. A curette was introduced and a mass of polypoid granulations removed from all directions. The opening into the nose was found and freely enlarged and curetted. The cavity was next swabbed out with chloride of lime, and after a thin drainage-tube had been passed into the nose from the trephine opening the parts were adjusted and the patient sent to bed.

Mr. Collier drew attention to the fact that before commencing the operation a sponge had been placed in the posterior nares to prevent blood and the contents of the frontal sinus passing into the larynx *via* the infundibulum. The neglect of this precaution in a previous case, he said, had nearly caused a fatal ending. The points to be observed in this case, he thought, were: the unusual site of the sinus, the absence of bulging of the orbit, the absence of previous symptoms of trouble in the frontal sinus. So far as the operation was concerned it was important, he said, to open the sinus above the infundibulum and in a position where every part of the cavity could be inspected and curetted; after the passage into the nose had been found it was important to widen this and to substantiate it by the passage of a thin rubber tube to assist in reforming the canal into the nose. All washing out, he remarked, was quite unnecessary; the tube should be removed in forty-eight hours and the opening in the forehead closed. The abscess was treated on simple surgical principles, and drained naturally in the best position, as any other collection of pus should be. Mr. Collier ventured to say that the case would be well inside a week.

CHELSEA HOSPITAL FOR WOMEN.

REMOVAL OF UTERUS AND APPENDAGES FOR EXTRA-UTERINE PREGNANCY AND DOUBLE PYOSALPINX.—DR. ARTHUR GILES operated on a married woman, æt. 28, who had been admitted with a history of symptoms of pelvic inflammation; she had been under the care of Dr. Mordaunt Wheler, of Battersea, who recommended her admission to the hospital. Menstruation had been irregular and somewhat profuse, and there had been no definite history of previous amenorrhœa; she complained of great abdominal pain which was referred especially to both iliac regions. On examination, the pelvis was occupied by a considerable mass rising into the lower part of the abdomen. It appeared to consist of a smaller medial and two larger lateral portions. On opening the abdomen there was evidence of pelvic peritonitis leading to numerous adhesions; after separation of these the uterus was seen pushed upwards and forwards by a large mass occupying the pouch of Douglas; on each side the tube was greatly enlarged and adherent to adjacent structures. With some difficulty the appendages were freed and removed, after which Dr. Giles proceeded to enucleate the mass behind the uterus; this proved to be a rather thick-walled cystic tumour the size of two closed fists; it contained old and recent blood-clots and some fluid blood; it had stripped up the peritoneum from the back of the uterus in such a way that this organ was considerably damaged, and the removal of the tumour left a ragged bleeding surface. As a means of securing complete control of the hæmorrhage it was deemed advisable to remove the uterus; this was done by supra-vaginal amputation, and the abdominal wound was closed by the usual three-layer method. Dr. Giles said that the presence of the large blood-clot introduced an element of difficulty into the diagnosis of the case even after the removal of the

diseased organs; it might be explained as a hæmatoma of the left broad ligament or as an extra-uterine gestation sac developing in the broad ligament and stripping up the peritoneum behind the uterus. In the latter case pregnancy must have started in the left tube, but in view of the somewhat disorganised condition of this tube, and the fact that it, like its fellow of the opposite side, contained pus, it would be difficult to understand the occurrence of tubal pregnancy. In the former case, that is, supposing the mass were a hæmatoma of the broad ligament, the association with pyosalpinx would be equally rare; he had, however, met with one or two instances of a hæmatoma independent of gestation associated with either tubal gestation or pyosalpinx of the opposite side; in such a case the hæmatoma was due to rupture of vessels in the broad ligament. It would, he pointed out, be necessary to submit the specimen to the pathologist for a report on its microscopic appearances. He considered that the removal of the uterus, although it slightly prolonged the operation, was the best course to adopt, because bleeding would be otherwise difficult to control, and the preservation of such a mutilated organ would serve no useful purpose after the removal of the appendages. The removal of the uterus in such a case, he pointed out, was not a matter of any difficulty; the chief difficulty in the operation, he said, was that which was incidental to nearly all operations for the removal of pus tubes, namely the separation of adhesions to bowel and other structures.

It is satisfactory to state that the patient left the hospital three weeks after operation having made an uneventful recovery. The pathologist's report was to the effect that the retro-uterine cyst was a gestation sac showing the presence of chorionic villi.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books &c.—Seven lines or under (70 words), 4s. 6d. per insertion 6d. per line beyond.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, MARCH 11, 1903.

THE USE AND ABUSE OF THE BROMIDES.

THE introduction of the numerous compounds belonging to the aromatic series has, to some extent, displaced the bromides from the preponderating position which they once occupied in the treatment of nervous and pseudo-nervous complaints.

Sir Samuel Wilks once devoted a humorous article to the subject of the indications for the administration of the bromides. With a praiseworthy spirit of self-immolation he feigned to have ascertained from his own note-books that in one case he had ordered the drug to relieve the anxiety caused by the loss of a favourite pug dog, in another the psychical disturbance was attributed to a love affair in which, as the Irishman observed, the reciprocity was all on one side, and it was prescribed as a matter of routine in affections differing as widely in their etiology as simple bad temper and overwork, over-feeding, and melancholia. Even now it can hardly be questioned that the bromides are administered far too generously and with a lamentable want of appreciation. In physiologically active doses the bromides are very apt to set up extremely disagreeable and even disastrous collateral effects, and it is to be feared that their toxic effects are not always clearly present in the mind of the prescriber. Cases of acute bromism are by no means rare in hospitals for the insane and much useful information might be gleaned in this direction from the experience of alienists if they were always on the look out for the characteristic manifestations and always gave us the benefit of their observations. The usual symptoms of bromism, as described by observers, consist of marked and persistent somnolence, mental depression, sluggishness of the mental processes, insensibility of the mucous membranes, abolition of the sexual functions and deep reflexes, a foetid odour of the breath, muscular weakness, dilated and irresponsive pupils, ptosis and general cachexia. In the more pronounced cases, usually the outcome of self-medication, the somnolence merges into stupor, the circulation becomes markedly impaired, and respiration is diminished in frequency. In certain cases, especially those in which the intoxication is moderate in degree but of long standing, the irritating effects of the drug are manifested on the skin, giving rise to troublesome pustulation. A factor which must never be overlooked is the extremely variable sensitiveness of the individual patient to the toxic influence of the drug. This variability is probably less a consequence of idiosyncrasy than of impairment of the eliminatory functions. Non-elimination, of course, implies accumulation, and the explosion of bromism which sometimes occurs several days after the administration has been abandoned is explained on the ground that the diuretic effect of the drug ceasing with its withdrawal the kidneys no longer carry on the excretion of the remainder. There is probably no drug so outrageously misused in the treatment of nervous disease as the bromides, although in reality their value in this field is very limited. The indications for their use may be found in mental disturbances characterised by nervous tension and excitability of the motor cerebral centres, but it is necessary to make a careful distinction in the type of nervous excitement, since there are many forms and but few of them present motor excitement as the primary feature.

THE DECENTRALISATION OF HOSPITALS.

THE question of the decentralisation of hospitals has an important bearing upon the future welfare of the medical charities of the United Kingdom. In the Metropolis the matter has recently been thrust into the forefront of discussion by the request of St. Bartholomew's Hospital for an enormous sum from the public in order to extend its site and to erect additional buildings. In response to a shower of hostile criticism a Committee of Investigation have resolved to proceed with the scheme. We are thus faced with the curious spectacle of the oldest and richest hospital in London going cap in hand to the charitable public and begging for a further vast endowment. The incident has naturally drawn a great and increasing attention to the relation of the great medical charities to the rest of the community. In endeavouring to lay before our readers the salient points of the case it should be clearly understood that we have no wish to select St. Bartholomew's Hospital for special criticism. At the same time that ancient institution forms so typical an example of the drawbacks as well as of the merits of the great central hospital that it may conveniently be taken as our concrete illustration. Within recent years London has undergone a great expansion, land has gone up in value by leaps and bounds, while there has been a steady exodus of resident citizens to the suburbs. The great hospitals which were founded to meet the needs of earlier days remain in their original position, so that we find within a central radius of about a square mile St. Bartholomew's, Guy's, King's College, Charing Cross, Westminster, the London, and St. Thomas's, with University College, the Royal Free, and St. Mary's, St. George's and others more or less closely adjoining. The hospitals remain, whereas the resident population of the central area has decreased on an average by 50 to 70 per cent., and in the City proper probably by 97 per cent. The migrating day population have their accidents and sudden sickness, but that alone would hardly justify the demands of the charities for vast and ever-increasing expansion. It is true that their wards are open for many provincial patients, but there is every reason to imagine that better accommodation could be provided for such persons in the suburbs than in the heart of a densely-populated town. It is a self-evident proposition that a large modern hospital, with ample inside and outside air-space, would be much more readily obtainable on cheap suburban than upon costly City land. The likelihood, indeed, might be roughly reduced to figures by taking the proportionate difference between ground that costs £500 and ground that costs £1,000,000 per acre. Do the public get value for their money when they subscribe to buy City land at the greater figure for the purpose of accommodating the sick? For our own part, we have little hesitation in stating our opinion that to enlarge central hospitals under such conditions is an unbusinesslike proceeding calculated on the whole to be injurious to the interests

alike of patients and of the charitable public. As to accompanying medical schools and honorary medical staff, there has never been any serious contention, so far as we are aware, that this part of the hospital organisation could not be readily transferred to the suburbs. Many medical students already live in outlying suburbs, and Peckham or Clapham Junction can be reached from Harley Street with no greater loss of time than would be entailed by a drive into the City. But in Peckham and Clapham and other suburban districts dwell millions of citizens who have to journey to the heart of Greater London to find hospital aid. The one great exception to that general statement, so far as the central area is concerned, is the London Hospital, which is still situated in the midst of a dense population. So far as accidents and emergencies are concerned, there would be no difficulty in case the main hospital were removed, in leaving behind an out-patient and casualty department, together with a sufficient number of beds for accidents and acute medical cases. From a common-sense point of view, to buy land at a million an acre in order to house sick patients from far and near in the midst of a city environment is to court ridicule. Yet that is the policy adopted by the authorities of St. Bartholomew's and of other central hospitals. It is easy to understand that City magnates and philanthropists interested in these charities find a central site more convenient to themselves, but it is hard to find other grounds for the maintenance of a system that furnishes no advantages commensurate with an enormous outlay.

SPORADIC SMALL-POX.

THE sporadic outbreak of small-pox in Dublin comes as an admonition to the sanitary authorities and the citizens generally that an epidemic of the disease is more than possible, it is probable, if the necessary steps are not taken to ward off such a terrible calamity. We will not enter on the consideration of the sanitary steps necessary to either avert or minimise the epidemic other than to recommend the best of preventives—vaccination and re-vaccination. The parent who neglects the duty of having his child vaccinated deserves to be punished. He is bound to protect his child against cold by clothing it, and against starvation by feeding it, and equally so against small-pox by having it vaccinated. So much for his duty to his child; but more than that there is a duty to the public. Every unvaccinated person not alone runs the risk of getting the disease, but he likewise becomes a distributing agent of the poison. This is well shown in the history of small-pox epidemics, which, as a rule, commence with a few cases, and then rapidly extend the area of distribution and enormously increase in number. The epidemic which started in London in 1901 did not assume formidable proportions until the beginning of 1902, when we find that during the week ending January 8th, there were 261 admissions into the hospitals of the Metropolitan Asylums Board.

The report of the same Board made on 1,027 cases under their care is a strong testimony to the value of vaccination and re-vaccination. Of the 1,027 cases in the Metropolitan Asylums Board hospitals during 1901, of 161 vaccinated cases, 3 died; of 101 unvaccinated cases 79 died; and of 12 doubtful cases, 7 died. All these patients were under twenty years of age, of those over that age, of vaccinated patients, 105 died; of 33 unvaccinated patients 19 died; and of 51 doubtful cases 34 died. But the value of the prophylactic power of vaccine is even better shown in the immunity it conferred on the attendants. Of 2,198 persons employed at the small-pox hospitals between 1884 and 1900 inclusive, in which period 17,900 small-pox cases were admitted into the hospitals, only 17 persons contracted smallpox, of whom 13 were not re-vaccinated until after they had joined the hospital, and 4 were workmen who escaped medical observation. To the above record we can add nothing that can enhance its value as an object lesson. We simply desire to draw attention to the facts, for since they were published in 1900 many things have occurred likely to displace the report from the memory of the man in the street.

Notes on Current Topics.

The Royal Orthopædic Hospital.

THE welfare of our medical charities is clearly a matter of first importance to the community at large. Upon that ground we venture to claim the attention of the public to the way in which the affairs of the Royal Orthopædic Hospital of London have been conducted of recent years. Some years ago the Committee desired to sell their valuable freehold site in Oxford Street for £32,000. They were thrown out, and the incoming Committee afterwards resolved to sell for £40,000. The sale has been all along strongly opposed by THE MEDICAL PRESS AND CIRCULAR and by other medical journals, inasmuch as no adequate grounds for that step were advanced. On October 8th, 1902, we criticised adversely a feeble attempt at justification of sale, published by Mr. Harry Marks (the Chairman), Mr. Ernest Flower (Deputy-Chairman), and Mr. Richard Martin (Treasurer). Their statement showed no compulsion to sell, and admitted that the hospital would not gain thereby from a financial point of view. From this brief summary it will be seen that the opponents of purchase advanced the selling price of the hospital by £8,000, and received outside support and sympathy. The senior surgeon, Mr. H. A. Reeves, led the opposition. It will hardly be believed that the Committee have now taken the extreme step of curtly dismissing him from his post as honorary surgeon to the institution. That course, we believe, is absolutely without precedent, and throws a sinister light upon the autocratic methods and the personal animosity that have been imported into the management of this charity. It is hard to believe that the President, Lord Denbigh, could have sanctioned a step of this high-handed nature upon an honourable opponent. We think

it due to the profession that the other surgeons connected with the hospital, namely, Mr. Henry Baker and Mr. Laming Evans, should at once dissociate themselves from the matter. Under the circumstances, moreover, any member of the profession will think twice before accepting a post that has been rendered vacant in the manner mentioned. We shall watch with some curiosity the future progress of the hospital under the present financial management.

Darwin and Vivisection.

THE rights of animals and the limitation of the power of man have for long been subjects which have furnished material for discussion, and it must be added, for dispute. And even still the principles underlying the practice of vivisection are by no means clear, and much of the differences of opinion in regard to the matter depend rather upon sentiment and emotion than sound scientific fact and clear logical inference. In the recently issued "More Letters of Charles Darwin" there is much that throws interesting light on the great scientist's relation to vivisection. Speaking of the practice of demonstrating on animals rendered insensible he says: "It is a most disagreeable and difficult one. I am not personally concerned, as I never tried an experiment on a living animal, nor am I a physiologist, but I know enough to see how ruinous it would be to stop all progress in so grand a science as physiology." Darwin also sympathised much with Dr. Ferrier in the vexatious prosecution to which he was subjected by the anti-vivisectionists, and was anxious to assist in meeting the heavy legal expenses incurred. It is a remarkable fact that although Darwin could not bear the sight of blood, and never engaged in experimental research on animals necessitating the use of anæsthetics, or associated with the production of pain, he nevertheless clearly recognised that man had a right to make use of lower organisms in his efforts to secure alleviation or removal of their and his sufferings.

A Curious Accident and its Sequel.

THE case with which a tooth can slip into the trachea during a series of extractions under an anæsthetic must have struck every medical man who has administered the anæsthetic in such cases. Fortunately, however, the accident is of extremely rare occurrence, as it is easy to understand that its results might be most unpleasant. A singular case has been recorded in a contemporary by Dr. Carnegie Dickson, of Edinburgh, where a swallowed tooth eventually produced symptoms almost identical with those of phthisis. In December, 1901, the patient had twelve stumps removed under an anæsthetic. The day after, he felt slight uneasiness behind the sternum, accompanied by a cough. This passed off, and he had no further trouble till the following January, when he had a severe attack of "influenza" accompanied by cough and muco-purulent expectoration. The "influenza" continued until March, when he got somewhat better, save that the cough and expectoration

toration continued, and he noticed a feeling of irritation behind the sternum. In July and August he went for a sea journey, during which time he improved, but some time after his return he again relapsed into the same condition, and, in January, 1903, he had a severe attack of hæmoptysis. A few days later, the hæmoptysis returned, and, feeling a "sort of obstruction in his chest," he coughed up a mouthful of red blood and an upper molar tooth with a cavity in it and ragged edges. Dr. Dickson and his father, who had both seen the case, never doubted but that the man was a victim of phthisis, of which he presented all the symptoms. Such a case could hardly be regarded as possible unless it had actually been observed. It conveys a strong lesson to dentists never to allow a tooth, or the fang of a tooth, which has dropped from the forceps to remain for a moment in the mouth, but to remove it before doing anything else.

Therapeutical Iconoclasts.

THERE are always a certain number of medical men imbued with an instinct which prompts them to tilt at accepted therapeutical dogmas. No sooner is it laid down that potatoes constitute an unsuitable article of dietary for diabetic subjects by reason of the starch they contain than up starts some enthusiast, not averse to notoriety *vice* fame, who declares on some more or less specious ground that they are not only not injurious but are positively curative. These are the people who prescribe an exclusively meat diet for gout, thyroid extract for Graves' disease, and so on; indeed, it would be easy to multiply examples of the eagerness with which anything partaking of the nature of a well-founded belief is challenged by individuals of heretical proclivities. It is, perhaps, well that it should be so. We are but too prone to crystallise our scraps of knowledge into dogmas and then complacently to consider that we have thereby added to the sum total of our acquirements. It is well that we should be constrained from time to time to defend our most cherished beliefs in the deadly breach, for if some then remain to comfort our advancing years others go by the board, demonstrating by their fall the fact that truth is relative and not absolute.

Compulsory Notification and Erroneous Diagnosis.

UNDER a system which compels the practitioner to attempt a diagnosis without waiting for any doubts to be removed a certain proportion of errors is inevitable, but it must be conceded that the proportion of errors which actually occurs is unduly large, and, moreover, it appears to be increasing. From a statement recently issued it appears that in 1889 no less than 1,583 persons, or 6.3 per cent. were sent to the hospitals of the Metropolitan Asylums Board who were not suffering from the disease cert fied. In 1900 the number was 1,706, or 7.9 per cent., while in 1901 the number reached 2,365, or 9.2 per cent. The percentage of errors was distributed as follows:—Scarlet fever, 5.6; diphtheria, 12.8; and typhoid

fever, 25.5. No less than 168 of the patients presented no symptoms of any obvious disease. Of the smallpox cases 13 per cent. turned out not to be suffering therefrom. In view of the facilities provided for the bacteriological and consultative confirmation of doubtful cases it is difficult to acquit the practitioners responsible for the erroneous diagnoses of a certain carelessness. The far too frequent occurrence of these errors points to the necessity for post-graduate instruction in the recognition of infectious diseases, and it behoves the Board to provide greater facilities for such instruction in their diagnosis and treatment. It must be remembered that a student may go through the whole curriculum without seeing more than one or two cases of infectious disease in an incipient stage, the only stage at which any difficulty in diagnosis is likely to be met with. He picks up a certain familiarity with them in practice, but this takes time and implies a proportion of errors inseparable from the process of self-instruction.

Bromine v. Chlorine.

EXPERIENCE has shown that the physiological effects of bromine are obtained with much smaller doses when chlorine salts are withdrawn from the dietary, moreover the gastric intolerance which so often imposes the abandonment of the treatment is less readily induced. Direct experimental observation proves that bromine can replace chlorine in the animal economy, so that by substituting the former for the latter an organic compound of bromine is formed which enables us to obtain the therapeutical effects of bromine in a more satisfactory manner. This fact renders it possible not only to administer the bromides in larger doses without producing inconvenient collateral effects, but allows of the drug being exhibited over long periods of time without the supervention of symptoms of intoxication. It is a good plan to give bromide of sodium instead of salt in the food, which should consist largely, if not exclusively, of cereals, milk and vegetables.

The Reliability of Morphia Tablets.

SOME short time ago, a medical man in Australia committed suicide by taking hydrocyanic acid. On his body were found several marks suggestive of a hypodermic needle, and empty tubes labelled morphia sulphate were found scattered about his room. There was also a statement signed by the deceased, in which he said that, although not addicted to the habit of taking morphia or any other drug, he had on the 9th September last taken within twelve hours no less than 43 grains of the sulphate of morphia "with little discomfort to himself." The morphia was taken hypodermically, Parke Davis tablets being used. This curious result led Dr. Reissmann, an Australian physician, to doubt the reliability of the tablets used, and he accordingly made a careful quantitative analysis in the laboratory of the University of Adelaide, not only of the tablets made by Parke Davis, but also of those made by Burroughs and Wellcome and

Mulford and Co. The results of his examination appear in the Australian *Medical Gazette*, and prove conclusively that the tablets contained the full specified dose, and were perfectly reliable. Accordingly, the case of the suicide must be regarded as one of an extraordinary, and, we fancy, record instance of toleration of morphia. The amount of that drug that morphia-maniacs are capable of absorbing is well known, but in this case that condition may be regarded as excluded, inasmuch as the statement written down by the deceased was apparently written with the genuine desire to communicate to his medical *confidés* the results of a unique experience.

The Ballachulish Quarry Dispute.

THE arbitrary attempt to displace the medical officer of the quarry workers has led to a deadlock, the issue of which cannot at present be foreseen. A large proportion of the men have already left the district rather than submit to dictation in a matter which so closely touches their well-being as the choice of a medical adviser, but the managers are "sitting firm," apparently in the fallacious hope that the affair will blow over. The men have now formed a committee to collect funds for the purpose of promoting an action, having for object to have the compulsory-leaving clause of the agreement declared null and void. As the men provide the medical officer's salary they claim the right to exercise a discretion in his selection all covenants to the contrary notwithstanding. We hope their appeal will prove successful, since it is of the highest importance to the profession and to the public that clauses having for object to prevent medical men exercising their calling in particular districts should be recognised as contrary to public policy. Dr. Grant's appeal against the recent decision affirming the validity of the contract will presumably stand over until this further action has been tried. We have every confidence that in equity the compulsory clause will be declared of no avail, and we cannot but admire the spirit of the men in suffering hardships rather than yield to what they very reasonably regard as a tyrannical exercise of managerial powers.

The Bacteriology of Acute Rheumatism.

As long ago as 1875 Klebs described micro-organisms present in rheumatic valvulitis, and in 1887 Popoff produced rheumatic lesions in animals by inoculating them with cultures obtained from the blood of rheumatic patients. Nevertheless, up to very recently there seemed to be but little unanimity among observers as to the appearance and reactions of the organism present. For instance, it has been described by some as a staphylococcus, by others as a streptococcus or diplococcus, and again as a large bacillus. Of late years, however, it has been fairly well established that the specific organism is a coccus, equally correctly described as diplo- or streptococcus. Dr. Ainley Walker, whose researches are the most recent (*Practitioner*, February, 1903), suggests the term *micrococcus rheumaticus* as the most convenient and accurate.

It is easily grown from the blood or urine of rheumatic patients during life, or from articular exudations or valvular vegetations *post mortem*. Inoculation in animals produces pericarditis, endocarditis, and arthritis—typically rheumatic conditions. Unfortunately, neither in appearance nor cultural reactions can the micrococcus be distinguished from the ordinary streptococcus of suppurative processes.

Modern Electrical Methods in Cancer.

THE general newspaper Press serves many useful purposes, but in our own country it is rarely made the arena of medical conflict. There are special circumstances, however, which render the subject of the modern electrical treatment of malignant disease an exception to that general rule. That certain superficial forms of cancer can be cured by exposure to the focus-tube is now confidently asserted. It is also claimed that a certain amount of control can thereby be exerted over post-operative recurrent nodules. Further, it is believed that in many cases of malignant diseases a beneficial effect is obtained by the use of the high frequency electrical current. The latter application has, indeed, in some instances been followed by apparent cure. The matter, however, has not yet been fully investigated, although it seems impossible to doubt that a potent weapon is being herein forged for the hand of the practical physician. The danger to the public arises from the fact that the medical profession has allowed Röntgen rays and other electrical work to drift largely into the hands of non-medical persons. The hospitals, even, have as often as not, given their X-ray apparatus to unqualified workers. Nemesis is now at hand in the springing up of a host of unqualified electrical specialists who will swell the horde of parasites hanging on the flanks of the medical army. The matter is now being disputed in the *Pall Mall Gazette*. Sir William Church, the late President of the Royal College of Physicians, has had the courage to send a signed letter to that journal pointing out the risks to the public arising from unqualified electrical treatment. Following his example, various other medical gentlemen, more or less qualified as electrical experts, have expressed their views in the same newspaper. The moral clearly is that medical men should entrust professional work whenever possible to properly trained and qualified men.

The Oyster Trade and the Ear Mark.

THE latest oyster scare, which began at Emsworth and finished at Southend, appears to have sounded the death-knell of a large and flourishing industry. At the best it will take years to restore the confidence of the public in oysters and cockles. In view of the large interests involved in the shell-fish trade it is curious that no decisive steps have been taken by owners and middlemen to reassure the public. If the companies are waiting for Government action in the purification of estuaries and sea coasts they are indeed leaning upon a broken reed. In the case of the Thames, for instance, the

necessary surveys and works for diversion of existing ways and means would take probably ten or twelve years. Where would the oyster trade be in half a score of years, especially as the Local Government Board is certain, sooner or later, to close all contaminated beds? The only practical step the companies appear to have taken is to secure certificates of purity from experts. That sort of document, however, obviously fails to reach the man in the street. What the consumer wants is some guarantee that every oyster he eats has come from a pure source. We have been favoured with the details of a plan which claims to be able to afford such a guarantee. It consists in the attachment, by an ingenious device, of a metallic disc to the flat shell of the oyster. The disc bears a date and the name of the guaranteeing company. The consumer, therefore, has only to turn over the shell of the oyster on his plate to see for himself the company's guarantee of freshness and purity. The mark appears to solve the problem in a simple and satisfactory fashion. The general desire for oysters is not lessened, although it has been reduced to vanishing point for the time being by the strongest of all possible human motives.

The Modern Sanitary Crusade.

THE aims of the sanitarian form on the whole one of the sanest and most practical of human ideals. He acts upon the Cromwellian principle of trusting in God while at the same time he keeps his powder dry. Before his steady strategy typhoid fever has been reduced to a tithe of its former virulence in the United Kingdom. That the disease still lingers here and there shows that the enemy's strongholds have not yet been thoroughly cleared out and his legions exterminated. But the sanitarian never loses heart, and he is even now taking steps to exclude many billions of typhoid bacilli hitherto scattered broadcast over the face of the land, securely stowed away within the shells of the costly oyster and the homely cockle. Then there is the great and difficult campaign against consumption. To prevent that malady, says the sanitarian, forbid spitting in public, isolate and disinfect cases as much as you can, exclude tuberculous cows from your dairies and farms, exclude tuberculous flesh from your meat supplies, insist on sanitary workshops and general housing environment and treat all tuberculous patients on the best modern lines. That is straightforward practical advice based on a scientific foundation. Another striking instance of a similar type is the killing of rats on board ship, because they carry the plague from one country to another. Fancy the scorn of our grandfathers if they were told that the lives of many thousands of their countrymen might be saved by attention to such matters as spitting in streets, the cleanliness of cowsheds and the wholesomeness of cows, the purity of water in oyster or cockle ponds, or the sickliness of the ordinary ship rat. So far is the attention to the rodent in question advanced nowadays that a steamer was promptly put into quarantine at Hamburg the other day because some bodies of

dead rats were found in the hold, although there had been no sickness among the sailors. It would be difficult to find a better example of the thoroughness that marks the methods of modern preventive medicine. *Sanitas, sanitas, omnia sanitas.*

Vaccination Legislation.

THE much-abused alternative for troublesome but urgent legislation, a Royal Commission, not being available in regard to vaccination, the Government have decided on another dilatory measure, in order, no doubt, to leave the burden of the fight to its successor, and the present Act is to be renewed for a year. This, of course, is what everyone anticipated when it was seen that no mention of impending legislation on this subject was made in the Royal speech. The incident reminds one of the answer of a celebrated statesman upon whom it was urged that war must break out sooner or later, to which he promptly exclaimed, "Then, for God's sake, let it be later!"

Post-mortem Examinations in Hospitals.

IT would be a good thing if it could be imposed as a condition of admission to the benefits of hospital treatment that a post-mortem examination on all patients dying in such institutions were an indispensable sequel. An absurd prejudice against these examinations is an article of faith with many, and much valuable pathological information is thus lost to science. Unless the circumstances are such as to justify an inquiry into the cause of death, we believe there is no legal impediment to the carrying out of such examinations, a dead body, according to law, not being vested in anyone. An action for trespass would only lie when the examination takes place in a private house against the will of the householder. At the same time it must be conceded that the prejudice is strong and, from a certain point of view, respectable, so that methods of persuasion are preferable to quasi-compulsion.

Damages for Mistaken Diagnosis.

SOME time since an action was brought against a practitioner in Holborn to recover damages for the removal to hospital of a child who was thought to be suffering from smallpox, a diagnosis which subsequent observation proved to be incorrect. The original action was dismissed on the ground that the claim disclosed no cause of action, and that the action not having been commenced within six months of the act complained of, the defendant was entitled to the benefit of the Public Authorities Protection Act, 1893. An appeal was entered against this decision, and this has been allowed, so that the case will come on for trial in due course.

WE are asked to state that the Annual Festival Dinner of the Irish Medical Schools' and Graduates' Association will take place in London at the Cafe Monico, Piccadilly, on St. Patrick's Day, March 17th, at 7.30 p.m. Tickets may be obtained from Mr. Charles Ryall, 51, Queen Anne Street, W.

Small-pox in the Provinces.

Small-pox continues to spread in the provinces, fresh cases being of daily occurrence over a very wide area, a fact of which the President of the Local Government Board professed ignorance when the subject of future legislation was brought before him. The most fertile source of infection is unquestionably the tramp, a very noteworthy proportion of the sufferers belonging to this class. Pretty well all the large towns of the north of England have found it necessary to take special precautions in view of the menace constituted by these constantly-recurring cases of infection. Since the beginning of the year no less than 2,397 cases of small-pox have been reported to the Local Government Board.

Chloretone in Sea-Sickness.

ON the principle that we should hasten to make use of a remedy while it cures, those of our readers who contemplate a sea voyage might do well to provide themselves with some tablets of chloretone. In five-grain doses this drug is claimed to afford marked relief from the distressing symptoms of this obscure disturbance. We must confess to a limited confidence in all methods hitherto suggested for the prevention or relief of sea-sickness, but it is our duty to register each new suggestion in the hope that one may ultimately make its way to the fore which will prove less disappointing than its predecessors.

PERSONAL.

PROFESSOR J. M. FINNY, M.D., has been elected King's Professor of Medicine in the School of Physic, Dublin, for a second period of seven years.

THE honorary degree of LL.D. will be conferred on Sir William F. Gairdner and Dr. Thomas Oliver at the graduation ceremony on April 21st.

MR. THOMAS WILSON, M.D. Lond., F.R.C.S., has been elected honorary obstetric officer to the Birmingham General Infirmary.

DR. C. W. DANIELS, of the Medical Department of British Guiana, has proceeded to the Federated Malay States for the purpose of taking over the office of Director of the Research Institute at Kuala Lumpur.

DR. MICHAEL CURRAN has been elected to the post of Surgeon to the throat department of St. Vincent's Hospital. Dr. Curran recently gained a Studentship of £400 in pathology and bacteriology in the Royal University of Ireland.

A DISCLAIMER.—Dr. Dundas Grant desires us to state that the report of an interview which appeared in the *Daily Telegraph* of March 3rd was published entirely without his authority or knowledge. Dr. Grant was quite unaware that the gentleman who engaged him in casual conversation in the office of the Secretary of the Hospital was a reporter.

A CONVERSAZIONE will be given at the West London Hospital by the Post-Graduate College, on Wednesday, the 18th instant, at 8.30 p.m.

THE annual general meeting of the Medical Graduates' College and Polyclinic will take place on March 31st, at 5.30 p.m.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

EDINBURGH.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH MORNINGSIDE ASYLUM.—Dr. T. S. Clouston's annual report on the Royal Asylum, of which he is medical superintendent, is always an interesting document, and the only regret is that this year he should have been prevented from presenting it in person on account of an illness, from which, however, he is now happily convalescing. Dr. Clouston alludes first to a slight increase in the numbers admitted, which with the high average of the last few years has led to chronic overcrowding, bad alike for the discipline and quietude of the wards and for the health of the inmates. The cause of disease which stood highest on the list for the year was intemperance, accounting for 28 per cent. of the admissions—the highest number yet recorded at Morningside. The standard of bodily health was particularly low, only 12 per cent. being an average condition on admission. The mean age of admissions steadily increases, having gone up from 40 to 43.3 this year. No fewer than fifty-six persons (13 per cent.) were cases of general paralysis, the largest number, except for last year, yet sent to Morningside, confirming Dr. Clouston's remarks in a previous report on the increase of the disease in the district. Of the 297 patients discharged, 134 were recoveries. So low a recovery rate as 31.6 per cent. is partly accounted for by the unfavourable nature of the admissions, many of whom suffered from senile decay and organic brain disease. The number of deaths, 138, has been the largest in the history of the institution, and is ascribed to the large number of bad cases admitted; to the overcrowding; to an outbreak of asylum dysentery, and to the inclement summer keeping the patients indoors. The most alarming event of the year was an epidemic of colitis, a disease first recorded by the writer in 1864-5. The present outbreak lasted from October 14th to January 8th, and affected twenty-seven female patients, of whom seven died. Only three could have been said to be in even fair health, and the condition of several was such that the disease could only be looked upon as a contributory cause of death. The epidemic was treated by the strictest isolation and disinfection. Some defective drains were found, and one new and important fact on the etiology of the disease was discovered in the fact that two cats in an affected area suffered from dysentery. Dr. Clouston thinks that the epidemic was predisposed to by the overcrowding; that it was actually introduced by defective sanitary arrangements, and that it was to some extent propagated in the house. The idea that incipient and transitory mental affections should be treated in a ward in the Royal Infirmary is again adverted to by Dr. Clouston, who is a strong upholder of the scheme. It is now taking root rapidly in America, and is carried out in several hospitals there.

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

MEMORIAL TO THE LATE PROFESSOR YOUNG.—It is very gratifying to be able to announce that the sum of £322 10s. has been readily contributed on behalf of the memorial to the late Professor Young, who so long occupied the chair of Zoology in Glasgow University. It has been decided by the committee in charge of the matter that the memorial shall take the form of, first, a medallion in bronze with marble frame, to be fixed in some suitable position in the Hunterian Museum, where the late Professor was in the habit of spending much of his time. Secondly, a volume containing a selection from his papers, as well as a biographical notice. Third, the catalogue of Hunterian MSS. to be printed. The expense of the latter part of the object will be met by one or two gentlemen. Only somewhere

about £60 is required to complete the scheme in full and there can be little or no doubt that, with the ready response already made, the remaining small sum will soon be forthcoming.

ACTION AGAINST A MEDICAL MAN.—An action is already raised in the Court of Sessions, or will be forthcoming at an early date, against an Ayrshire doctor for £1,000 damages for the death of a patient to whom he administered chloroform in order to break down adhesions in a stiff joint. The case is one the profession will look forward to with peculiar and painful interest. Pending Court proceedings it is, of course, undesirable to comment on the case in any way.

RESIGNATION OF SIR HECTOR CAMERON.—Sir Hector Cameron has tendered his resignation as representative of the Faculty of Physicians and Surgeons, Glasgow, on the General Medical Council. At the last meeting of the Fellows of the Faculty the following nominations were made for the much-coveted and responsible office. Dr. Lindsay Steven, Physician to the Royal Infirmary; Professor H. E. Clark, C.M.C., Surgeon, Royal Infirmary; and Dr. Bruce Goff, Bothwell. If the large body of Licentiates of the faculty had a voice in the election to this important office—which they have not—they would have no difficulty whatever in making a selection from the above list of names. Many of the Fellows know pretty well who is the favourite with the Licentiates, and therefore it would be a very gracious act on their part were they to recognise this fact on the day of election. Competition is sure to be keen, and if one candidate more than another is specially anxious to secure the office, that one is probably not an all-round favourite. It would not be at all out of place were the Licentiates, who are a numerous body, to use their influence with those Fellows with whom they are acquainted, in favour of the candidate best known to them.

SUPPURATION WITHIN THE TEMPORAL BONE AND ITS CONSEQUENCES.—At the fortnightly meeting of the Southern Medical Society, held on Thursday last, Dr. James Kerr Love gave a most interesting and peculiarly instructive demonstration on "Suppuration Within the Temporal Bone, and its Consequences." It was illustrated by means of beautiful lantern slides showing the normal anatomy of the temporal bone, and also the effects of suppuration in the tympanic cavity. Patients were present who had been successfully operated upon, and there was a splendid display of stereoscopic views. The various instruments used in operations on the ear were also exhibited. Dr. Love described very fully and clearly the various steps in the radical operation and the advisability of using Stacks' guide by way of protecting the facial nerve from injury in course of the operation. In the discussion which followed, Dr. James Erskine said that if such instructive demonstrations were given more frequently, the general practitioner might operate himself oftener than he does in cases of mastoid disease, &c. He urged the necessity in all cases of scarlet fever and diphtheria of having the ears carefully examined and where any disease was discovered, of having it immediately treated. Dr. Alfred Young and Dr. Walter Downie also took part in the discussion. It was generally recognised that Dr. Love's demonstration was one of the best of a very good series. There was a large attendance of members.

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

CONSUMPTION IN BELFAST.—At the weekly meeting of the Public Health Committee of the Belfast Corporation, held on March 5th, a letter was read from the Local Government Board asking what steps had been taken towards carrying out the Board's suggestion for preventing the spread of consumption in the city. These suggestions were contained in a circular, dated September, 1901, and included, it is reported, among other things, the establishment of municipal sanatoria. The Health Committee claim to have given serious consideration to the question, and profess to be willing to do anything in

their power, but they hesitate to impose the serious burden of municipal sanatoria on the rates. The Medical Superintendent Officer of Health (Dr. Whitaker) reported that he had carried out the suggestions of the Board as far as it lay in his province to do so. Literature has been distributed, and three female sanitary inspectors have paid large numbers of visits to houses in which cases of consumption have occurred, giving instruction to the people in hygienic matters. All cases of death from phthisis are to be notified to the Committee by the burial authorities, and efforts are being made to have consumption included in the list of notifiable diseases. The Health Committee decided to reply to the Local Government Board that they were doing all they could in the matter.

The chairman of the Health Committee made the somewhat astounding statement that Belfast is the healthiest part of the United Kingdom just now. But, as the *Northern Whig* remarks, it is hard to believe that statement when we find that nearly half the deaths in the city arise from "phthisis and diseases of the respiratory organs." In Dr. Whitaker's last monthly report he stated that 256 out of a total of 651 deaths in the period named were due to these causes, and this was not exceptional, for in the corresponding period of last year the death-rate from all causes was 20.8 per 1,000 per annum, and from chest affections 9.7 per 1,000 per annum. It looks, therefore, as if the statement referred to were due more to a leaning towards official whitewash for a dark stain on our city than to a desire to face the facts as they are.

Correspondence.

ROYAL ORTHOPÆDIC HOSPITAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I enclose copy of a letter which the secretary of this hospital was directed to address to me, and which sets forth that at a recent annual meeting of the Governors I was not re-elected. I was not present at this meeting, nor were any of the Governors who are opposed to the sale of the site, several of them having resigned, disapproving of that policy. I am not aware that any reason was given for my non-election, nor have I received any complaint about my work.

It remains to be seen if this unprecedented action will be in the interest of the hospital or to the credit of its management, but it is undoubtedly contrary to the laws of the hospital applying to the medical staff, and in that sense illegal. Law 40 provides "that no medical officer shall be removable except by the vote of a general or special court on the report of the Committee of management." But the Committee made no report that I have heard of or seen. Hence a serious step has been taken against me, and I have suffered injury unheard and without sufficient or any cause assigned. As this is a matter which affects the position of the medical and surgical staffs of all hospitals, it is one which, I venture to think, will attract the attention of medical journals, and, through them, of the profession at large.

I am, Sir, yours truly,

H. A. REEVES.

[COPY.]

Royal Orthopædic Hospital,

February 27th, 1903.

DEAR SIR,—I have to inform you that at the annual Court of Governors held yesterday you were not re-elected upon the Committee of Management, from which you some time ago gave notice of your intention to retire.

The Governors did not re-elect you either as one of the Honorary Surgeons, but thinking you would prefer to finish the treatment of certain of your patients no immediate steps have been taken regarding the appointment of a successor.

I am, dear Sir,

Yours faithfully,

TATE S. MANSFORD.

H. A. Reeves, Esq.

SEMI-TOTAL PLEDGE ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am much obliged to Dr. Sers for calling attention to the words printed on the back of some of our pledge forms, issued in the first week or two of our existence "Total abstinence is always the best policy," because it gives me opportunity to explain.

These words I took exception to myself as soon as they were in print, and suggested the word "often" for "always." This the committee agreed to, and, as you will see from the enclosed, the form has already been printed with the word "often" substituted, and is now in circulation to the number of some 15,000 or more.

I may add that these forms are now superseded by the pledge card, which, of course, contains no such clause nor any other for that matter touching the question of total abstinence.

Your obedient servant,

G. H. F. NYE, Hon. Secretary.

35, Chapel Street, Belgrave Square, S.W.

March 5th, 1903.

COLLECTIVE INVESTIGATION OF PUERPERAL ECLAMPSIA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The request of the Clinical Society of Manchester for reports of cases of eclampsia is meeting with a hearty response from medical men all over the country. The committee would like to point out that a diminution in the excretion of urea is coming to be regarded as an important physical sign of the pre-eclamptic state, more important, perhaps, than albuminuria.

The vital point is one on which they hope their investigation will throw much light, and reports which give quantitative estimations of urea, and daily quantity of urine, will be doubly valuable for this reason.

The use of the hypobromite process with Southall's Ureometer is very simple, and the apparatus is inexpensive (it can be obtained through any chemist for about 3s.) * It may perhaps be hoped that those who are favouring us with reports of cases will find time to furnish data, enabling us to correlate the output of urea with the gravity of the case.

We are, dear Sir

Yours faithfully,

T. ARTHUR HELME, President.

J. PRICE WILLIAMS, Swinton, Manchester,
Hon. Secretary for the Investigation.

J. HOWSON RAY,

Hon. Secretary Clinical Society.

22, St. John Street, Manchester,
March 4th, 1903.

Obituary.**DR. M. H. MACNAMARA.**

WE regret to announce the death of Surgeon-Major Macnamara, which event took place at his residence, 8, The Mall, Waterford. Dr. Macnamara belonged to an old Clare family who for centuries resided in the parish of Kilneboy, near Lake Inchiquin. The deceased gentleman in 1888 became a Fellow of the Royal College of Surgeons and a D.P.H. of the same College. Since he retired from the Army Medical Service he practised medicine in Waterford, where his kindly sympathetic nature won him hosts of friends, and his skill as a physician and his unremitting care of his patients secured respect and admiration from rich and poor.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Medical Sickness Annuity and Life Assurance Society was held at 429, Strand, London, W.C., on 27th ult. There were present Dr. de Havilland Hall, in the chair; Dr. J. B. Ball,

Mr. Wm. Thomas (Birmingham), Mr. J. Brindley James, Dr. J. F. Allan, Dr. St. Clair, B. Shaflwell, Dr. M. Greenwood, Dr. J. W. Hunt, Dr. A. J. Rice Oxley, Dr. W. Knowsley Sibley, Dr. Walter Smith, Dr. Fredk. S. Palmer, Mr. F. S. Edwards, and Dr. Alfred S. Gubb. As is usual at this time of the year the Society is receiving a large number of claims for sickness benefit, and the claim list has been somewhat abnormally swollen by the epidemic of influenza. However, although numerous, the claims are for the most part of short duration, and the large reserves of the society continue to grow. The accounts for 1902 show that the sickness branch of the society's business has largely grown during the year, having, in spite of a heavy claim account, considerably increased its reserves. The number of those members who are permanently disabled, and in consequence drawing pensions, usually one hundred guineas a year, is still growing, and the disbursements in respect of these cases form an important item in the accounts. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary Medical Sickness Society, 33, Chancery Lane, London, W.C.

Congress of the Sanitary Institute.

THE twenty-first Congress of the Sanitary Institute will be held at Bradford, from July 7th to July 11th, 1903. President: The Right Hon. the Earl of Stamford. Section I.—Sanitary Science and Preventive Medicine—will be presided over by Professor Clifford Allbutt, M.A., M.D., F.R.C.P., D.Sc., F.R.S., J.P., D.L. Section II.—Engineering and Architecture—will be presided over by Maurice Fitzmaurice, C.M.G., M.Inst. C.E. Section III.—Physics, Chemistry, and Biology—will be presided over by Professor C. Hunter Stewart, D.Sc., M.B., C.M., F.R.S.E. The lecture to the Congress will be given by J. Slater, B.A., F.R.I.B.A. Eight Technical Conferences will also be held in connection with the Congress, presided over by Councillor W. C. Lupton, Professor Thomas Oliver, M.A., M.D., F.R.C.P., J. Spottiswoode Cameron, M.D., B.Sc., T. H. Yabbicom, M.Inst.C.E., C. Drabble, M.R.C.V.S., Mrs. Moser, James Kerr, M.A., M.D., D.P.H., and Mr. Isaac Young.

An Agile Nurse.

IN view of the recent outbreak of smallpox in Barnsley, certain precautionary measures were decided upon, *inter alia*, all leave of absence to the staff being withheld. However reasonable this measure may have been it was hardly to be expected that the nursing staff would acquiesce therein and consent without a murmur to cancel all engagements. One of them promptly gave notice and rather than miss her appointment she climbed over a ten-foot gate and regained her freedom which, as far as the guardians are concerned, she is likely to retain. It appeared that the Board had agreed to grant the nurse a testimonial, but in view of her escapade this decision was revoked.

The Medical Congress at Madrid.

THE Fourteenth International Medical Congress, which meets at Madrid in April, promises to be a success if the number of foreign delegates and members may be taken as an index. Upwards of 1,200 medical men from all parts of the world have intimated their intention of joining, and notice of close upon 250 papers has been given. Accommodation has been arranged for the reception of the members and their families, and extensive arrangements have been made in view of the social side of the meeting.

Trichinosis in Spain.

THE Duke and Duchess of Tarifa and a number of their friends are stated to be suffering from trichinosis consequent upon the consumption of some sausages which were partaken of on the occasion of a visit to the ducal estates in Andalusia. According to the text-books the disease is invariably fatal, but possibly the Spanish trichina may prove less lethal than its German colleague.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE ACQUISITION OF SWEDISH GYMNASTICS.

In reply to the enquiry of "Nurse Lever," an esteemed medical correspondent in Sweden has sent us the following information:—"The best address for her to go to will be Dr. A. Wide, Brunkebergstorg 13, Stockholm. The course will take two months, either April and May, or October and November. The fees to be paid are about £11. English is spoken, and the doctor has written a little book in English on Medical Gymnastics. He would be willing to give any further information, if the nurse wishes to apply to him."

Q. R.—The mortality from operation for the radical cure of hernia is under 5 per cent., in fact, it ought not to exceed 1 per cent. in uncomplicated cases. The ultimate success, that is to say the permanency, of the result is not a matter upon which one can dogmatise, but, on the whole, it may be regarded as promising.

ADRENALIN.—The application of solutions of Adrenalin, in the treatment of so-called "colds," cannot be more than palliative, but the relief, ephemeral though it be, is often very marked. Of course, the so-called "colds" are, in the majority of instances, nothing but microbial catarrh of the nasal mucosa, and are predisposed to by living in too confined an atmosphere.

V. G. S.—You have obviously rendered yourself amenable to disciplinary measures, and you would do well to disarm the authorities by an expression of regret, coupled, if it can be done conscientiously, with the assurance that your conduct was due to inadvertence, and will not be repeated.

"SPIRIT OF HUMANE BLOOD."

In 1684, as in 1903, there were many scientists bent on curing consumption, and in a Medical Journal of that date, with "Communications from diverse Learned Physicians," one of them writes a long and detailed article on the "Vertues of Humane Blood" for this disease. "A young lady, in whose Family the consumption was an hereditary disease, was not to be eased but by a reasonable remove from London into the French air, but she was so weak it was feared she would dye before she could go. Whereupon the author sent her some spirit of Humane Blood very carefully prepared, upon which she manifestly amended, and went in February to Montpellier, whence she brought home good Looks and Recovery." Perhaps Montpellier was a more powerful factor than the "humane blood" in bringing this about: "Hypophosphopathy" is the name given by a Boston paper to a cure for consumption.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 11TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. W. MacAdam Eccles: The Vermiform Appendix—Some Points in its Anatomy and Pathology.

SOUTH-WEST LONDON MEDICAL SOCIETY (Bolingbroke Hospital, Wandsworth Common).—8.45 p.m. Paper:—Mr. M. Shield: Some Recent Experiences in Diseases of the Breast.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

THURSDAY, MARCH 12TH.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. I. Parsons and others. Paper:—Mr. S. Bishop: Procidencia Uteri, with Special Reference to an Operation upon the Sacro-Uterine Ligaments. Discussion continued.

FRIDAY, MARCH 13TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. W. MacAdam Eccles: The Vermiform Appendix.—Some Points in its Anatomy and Pathology.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, W.).—8 p.m. Card Specimens:—Mr. C. B. James, Dr. L. Buchanan, Mr. S. Mayou, Mr. A. Lawson, and Dr. W. E. Thomson. 8.30 p.m. Papers:—Mr. E. T. Collins and Mr. J. H. Parsons: Anophthalmos in a Chick. Mr. S. Mayou: Treatment of Trachoma by X Rays. Dr. W. E. Thomson and Dr. L. Buchanan: An Account of Certain Cases of Injury to the Eye of the Child during Labour. Mr. J. B. Lawford: Notes of a Case of Dislocation of the Eyeball.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11 Chandos Street, Cavendish Square, W.). 4 p.m. Papers will be read and Cases shown by Dr. J. Horne, Dr. J. E. McDougall, Dr. Lodge, Mr. M. Collier, and Dr. D. Grant. 8 p.m. Annual Dinner at the Imperial Restaurant.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers:—Mr. T. S. Ellis, Skin Sliding. Dr. W. H. B. Brook: Spinal Curves with Total Paraplegia, Costotransversectomy with Complete Recovery. Mr. S. Paget: Successful Treatment of Prolapse of Bowel with Incontinence by Injection of Paraffin under the Mucous Membrane.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi Terrace, Strand, W.C.).—8 p.m. Paper:—Dr. J. M. Wilson: Regulations under the Dairies, Cowsheds, and Milkshops Orders.

Appointments.

Adams, J. E., L.R.C.P.Lond., M.R.C.S., Assistant House Surgeon to St. Thomas's Hospital.

Barbour, J. M., M.B., C.M.Glasg., Medical Officer of Health for Ramsey, Isle of Man.

Bevan, A., M.B., L.R.C.P.Lond., M.R.C.S., Clinical Assistant in the Ear Department at St. Thomas's Hospital.

Boycott, A. E., M.A., M.B., B.Ch., B.Sc.Oxon., House Physician to St. Thomas's Hospital.

Bradford, A. B., M.B., B.S.Durh., House Surgeon to St. Thomas's Hospital.

Carpmael, N., L.R.C.P.Lond., M.R.C.S., Assistant House Surgeon to St. Thomas's Hospital.

Flower, Frederick J., M.R.C.S., M.S.A.Lond., Medical Officer of Health for the Warminster Rural District.

Fox, Ida E., M.B., B.S.Durh., House Surgeon to the East End Branch of the Children's Hospital, Sheffield.

Glenville, W. M. G., B.A., M.B., B.Ch.Oxon., Junior Obstetric House Physician to St. Thomas's Hospital.

Guthrie, T., B.A.Cantab., L.R.C.P.Lond., M.R.C.S., Clinical Assistant in the Skin Department at St. Thomas's Hospital.

Hedley, J. P., M.A., M.B., B.C.Cantab., House Surgeon to St. Thomas's Hospital.

Henderson, T. B., M.A., M.B., B.Ch.Oxon., House Surgeon to St. Thomas's Hospital.

Hudson, A. C., M.A., M.B., B.C.Cantab., Junior Ophthalmic House Surgeon to St. Thomas's Hospital.

Leach, R. E. H., B.A.Oxon., L.R.C.P.Lond., M.R.C.S., Clinical Assistant in the Throat Department at St. Thomas's Hospital.

Loosely, A. E. A., B.A.Oxon., L.R.C.P.Lond., M.R.C.S., Senior Ophthalmic House Surgeon to St. Thomas's Hospital.

Nolan, W., L.R.C.S.Irel., L.R.C.P. & L.M., Clinical Assistant to the Chelsea Hospital for Women.

Rob. J. W., B.A., M.B., B.C.Cantab., House Surgeon to St. Thomas's Hospital.

Sears, C. N., L.R.C.P.Lond., M.R.C.S., House Physician to St. Thomas's Hospital.

Shipman, G. A. C., M.A., M.B., B.C.Cantab., Senior Obstetric House Physician to St. Thomas's Hospital.

Spriggs, E. J., M.D., M.R.C.P., Physician to Out-patients to the Victoria Hospital for Children, Chelsea.

Upcott, H., L.R.C.P.Lond., M.R.C.S., Assistant House Surgeon to St. Thomas's Hospital.

Vacancies.

Durham County Asylum.—Second Assistant Medical Officer. Salary £180 per annum, with rooms, board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

London Fever Hospital, Liverpool Road, N.—Assistant Resident Medical Officer. Salary £120 per annum, with board and lodging. Applications to the Secretary.

Derby Borough Asylum.—Assistant Medical Officer. Salary £120 per annum, with board and washing. Applications to Dr. Macphail, Rowditch Derby.

The Royal National Hospital for Consumption and Diseases of the Chest, Ventnor.—Assistant Resident Medical Officer. Salary £100 per annum, with board and lodging in the hospital. Applications at once to the Secretary, 34, Craven Street, Charing Cross, London.

Bracebridge Asylum, near Lincoln.—Junior Assistant Medical Officer. Salary £125 per annum, with furnished apartments, board, attendance, &c. Ladies only are eligible candidates. Applications to W. T. Page, Junior, Solicitor and Clerk to the Visiting Committee, 5 and 6, Bank Street, Lincoln.

St. Peter's Hospital for Stone, &c., Henrietta Street, Covent Garden, W.C.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to Irwin H. Beattie, Secretary.

North-Eastern Hospital for Children, Hackney Road, N.E.—Resident Medical Officer. Salary £120 per annum, with board, residence, and washing allowance. Applications to T. Glenton-Kerr, Secretary.

West Riding Asylum, Wakefield.—Assistant Medical Officer. Salary £140 per annum, with apartments, board, washing, and attendance. Applications to the Medical Director at the Asylum.

Births.

BROCK.—On March 4th, at 77, Fellows Road, S. Hampstead, the wife of J. H. E. Brock, M.D., F.R.C.S., of a son.

DIHEL.—On March 5th, at Royal Palace Hotel, Kensington, W., the wife of Dr. Ludwig Diehl, of a daughter.

GOWLAND.—On March 3rd, at Newton Lodge, Faversham, Kent, the wife of Edward Lake Gowland, M.B. Lond., &c. of twin sons.

JOY.—On March 4th, at Bradford, near Reading, the wife of Norman H. Joy, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

CRONIN—TOWNSEND.—On February 28th, at Otway Station, Punta Arenas, Chili, Eugene Amyatt Cronin only son of Eugene Francis Cronin, M.D., of Old Manor House, Clapham Common, to Muriel, third daughter of Meredith Townsend, M.R.C.S.E., of Upper Phillimore Place Kensington.

EARLE—YEOMAN.—On the 5th March, at all Saints' Church, Northallerton, Walter George Earle, M.R.C.S., L.R.C.P., son of the late Frederick Earle of Burton-on-Trent, to Annie, younger daughter of the late John Yeoman of Rueberry, Osmotherley.

WYNNE—TICKELL.—On March 3rd, at Padstow Parish Church, John Kendrick Wynne, M.D., of St. Ives, Cornwall, to Gwen, youngest daughter of the late John Arscott Tickell, 3, Mutley Park Terrace, Mannamead, Plymouth.

Deaths.

CORNISH.—On March 7th, at 102, Shaftesbury Road, Brighton, of apoplexy, George Bishop Cornish, M.D., late of Taunton, aged 68.

EVANS.—On March 5th, at 57, Harley Street, W., the residence of her son-in-law, Dr. Heron Harriet Ursula Evans, widow of the late Charles Evans, M.R.C.S., and daughter of the late Francis William Cobb, of Margate, aged 88.

Original Communications.

TUBERCULOUS PERITONITIS.^(a)

By GEORGE CARPENTER, M.D. Lond.,
Physician at the Evelina Hospital for Sick Children.

TUBERCULOUS peritonitis is met with in practice under several fairly well-defined clinical conditions, and it is therefore possible to arrange these cases with some method. These clinical conditions are:—

1. A matted condition of the bowel which is often, but by no means necessarily, associated with tuberculous intestinal ulceration and caseous disease of the mesenteric glands; a disease called *tabes mesenterica*, which has the well-known clinical features of a tumid abdomen, abdominal pain, diarrhoea, wasting, and sometimes faecal fistula at the umbilicus.

2. A condition in which a child is out of health, has a full stomach, and complains of griping pains there. Under examination, hard and fixed lumps are felt in one part or another of the abdomen usually close under the parietes, but not always so. The disease is due to the luxuriant growth of miliary tubercles in large masses. This will often occur in the omentum, which becomes much thickened and contracted into a thick band, and stretches horizontally across the upper part of the abdomen. Sometimes a large mass, or plate, forms between the liver and the diaphragm, but here, of course, not recognisable clinically. At other times the omentum forms a thick apron, which lies in front of the intestines, and is adherent to them, and to the liver, spleen, and abdominal parietes. Such a thickened mass often has areas of varying density and induration, which may be felt as isolated nodules of superficial-lying thickening underneath the abdominal wall. Or, a mass may form in Douglas's pouch which can be detected on making a rectal examination. Again, tuberculous masses may be felt in any part of the abdominal cavity, and these are mostly intestinal coils matted together with tuberculous deposit outside the bowel, a fact which explains a clinical feature that is often puzzling, viz., that the tumours are constantly varying in size and definition. There is also another practical point of some interest and that is, the bowel may be obstructed by the tuberculous deposit enveloping it inducing tormina, borborygmi, and obvious peristaltic movements of the greatly distended gut which terminate at the seat of obstruction, and perhaps occasions thereby a group of symptoms which may lead to the suspicion of chronic intussusception. The tuberculous tumour, the most common variety of tuberculous peritonitis, is not often associated with much ascites. In the course of the complaint a certain amount of fluid may come and go, but the quantity is not often great, though it may be so large as to mask the underlying mischief.

Fixed lumps may be due to caseation of the mesenteric glands alone. Such glandular masses may be so matted together as to form a large fixed tumour,

or they may retain their original isolated positions and be felt through the abdominal wall and bimanually per rectum, as a characteristic grape-like mass. Such cases often find their way into the wards of a hospital, not for this complaint, but as instances of tuberculous meningitis, or of broncho-pneumonia, or of a child wasted to a skeleton and in a state of collapse from diarrhoea. Sometimes their abdominal condition is recognised during life, but intestinal ulceration and caseous mesenteric glands often escape detection, and are found in the post-mortem room. In a girl, æt. 10, a fixed tumour was due to the following condition:—The morbid changes were limited to the small intestine, commencing about two feet above the ileo-cæcal valve. Here, and for some little distance down to within six inches of the valve, there was extensive intestinal ulceration together with caseation and matting of neighbouring glands, the whole being knotted together by dense adhesions. Some of the ulcers were of cartilaginous hardness. The rest of the abdominal cavity was quite free from disease. There was secondary tuberculous lung disease. The limited extent of the disease suggests the idea that it might have started in a mild attack of enteric fever. In some instances, when an opportunity has presented itself of making a post-mortem examination of cases occurring in this group, I have also found caseation of the mesenteric glands and intestinal ulceration, and such are clinically allied to the group of cases occurring under heading No. 1.

The amount of febrile disturbance is not great, although exceptions do arise, and well-marked instances of remittent and intermittent types of fever are seen. A fairly constant feature is the large proportion of subnormal temperatures encountered in this disease. Day after day the temperature may be found ranging between 98° F. or 97° F., or even lower, with occasional rises to 99° F., or thereabouts. These cases often linger on week after week and month after month without any marked alteration either way, and frequently leave the hospital improved in regard to their general health, though the tuberculous tumour remains much as before.

Under heading 3 are cases that come under observation as examples of ascites. Throughout their illness the condition may begin and end as one of ascites. Perhaps a rectal examination may reveal some slight thickening in the abdominal cavity which would have escaped detection by the ordinary methods of examination. Ascites may mask the condition of tuberculous tumour just mentioned, and it is not until a paracentesis abdominis has been performed, or the fluid has become absorbed, that the underlying mischief is detected. The converse may also happen, but this is not so common. As an uncommon sub-variety may be mentioned that condition in which fluid is encysted among the intestinal coils, and under this variety may be grouped cases which come under notice as *localised tuberculous abscesses*. Variations are sometimes noticed in the character and behaviour of the abdominal contents. Thus in a case of abdominal distension, sometimes there may seem to be a large quantity of fluid, and at other times the contents appear to be chiefly gaseous. Such variations succeed one another quickly. When fluid

(a) Paper read before the Society for the Study of Disease in Children at the Discussion on Tuberculous Peritonitis, on December 13th, 1902.

seems to be present in the abdomen, and behaves in the manner described it is probable that fluid is really there, and that instead of being definitely encysted in one particular locality or free in the peritoneal cavity it is held by the intestinal coils, and that as these alter in position and distension so the evidences of the fluid alter and alternately appear and disappear.

The febrile symptoms and fever encountered in ascites are not marked. The temperature may be raised for a day or two to 100° F. or to 100° F., and usually quickly subsides. On the other hand remittent or intermittent types of temperature may be found in those who ultimately recover.

4. There is a type of tuberculous peritonitis in which the abdomen is greatly distended, tense, and drum-like, and offers great resistance to manipulation. It may happen that nothing abnormal can be felt by a bimanual examination, but, on the other hand, there may be a suspicion of peritoneal thickening, and sometimes dull areas may be mapped out on percussion of the abdominal walls, quite apart from obvious thickening. Given fever of a remittent type, pea-soup-like motions, possibly some splenic enlargement, moist sounds in the chest, drowsiness, and some delirium, all of which may happen in combination in such a case, and it is not difficult to mistake the condition for that of enteric fever. Subsequently there may be effusion of fluid, or definite lumps may make their appearance, or the bowels may be found to move under the hand *en masse*. On the other hand, the primary condition may clear up without any further developments. In infants and young children, the condition which is most likely to be mistaken for it is that of chronic gastrointestinal catarrh from improper feeding; a bimanual examination in such a case may prove decidedly helpful.

The foregoing remarks are the outcome of a study of ninety-one cases of tuberculous peritonitis which have been under the writer's care during past years. Of these cases fifty-five were males and thirty-six were females.

Phthisical History.—In thirty-two of these cases there was a family history of phthisis or other tuberculous affection; in twenty-nine cases there was no history of such; and in thirty cases the notes were not sufficiently precise on the subject to make them of value. About half the number of cases, where an inquiry had been made, gave a history of tuberculous affections.

Age Incident.—Their ages were as follows:—

| Months. | Years. |
|-----------------|-----------------------------|
| 3 6 9 12 18 | 2 3 4 5 6 7 8 9 10 11 12 13 |
| Cases:— | |
| 2 0 2 8 4 | 15 19 4 12 3 5 5 3 5 3 0 1 |
| Total—91 cases. | |

A little more than one-sixth of the total number of cases arose within the first 18 months of life. From this period to within six years of age there were no less than fifty cases—or close on five-ninths of the total number of cases; the disease appears, therefore, to be more common about this period of childhood than at other times.

Enlargement of the Liver.—During and within the first two years of life four cases, or two-sevenths of the number were associated with an enlarged liver; one child died, and its liver was found to be "nutmeg." From two years to within six years of age there were five cases, or one-tenth of the number; one died, and its liver was found to be fatty. Of these cases, in every instance but one, the spleen was also enlarged.

Enlargement of the Spleen.—During and within the first two years of life there were five cases with enlarged spleens, or in five-sixteenths of the cases; one of them died. From two years to within six years of age there were eight cases of splenic enlargement, or eight-fiftieths of the cases, and three of these died. Of the deaths one was that of a child just over two years old; its spleen, though enlarged, was free from tubercles. In the other instances the enlarged spleens contained miliary tubercles. The most prolific periods for splenic enlargements from all causes are first, during the first eighteen months of life, and secondly, and to

a less extent from then up to the fourth year. (a) A. these stages splenic enlargements are quite common. Splenic enlargements associated with tuberculous peritonitis have been, in my experience, infrequent and uncommon, in comparison.

Phthisis.—This occurred in sixteen cases, and in four of them within the first two years of life. Of the four cases three died, and in one there was caseous pneumonia, and in another miliary tuberculosis of the lungs. In my experience obvious phthisis has not been a common clinical complication.

Pleurisy.—Of this complication I possess but one clinical record, viz., that of a child, æt. 3, previously mentioned, who succumbed to empyema.

Tuberculous Disease of the Male Genitalia.—Five of the cases of tuberculous peritonitis were associated with the above complications. In a boy, æt. 11, the vesiculæ seminales were tuberculous. In a boy, æt. 5, there was tuberculous of the seminal vesicles, the prostate, and the body and epididymis of one testicle. A boy, æt. 6, had caseous epididymitis with a corresponding caseous seminal vesicle. In a boy, æt. 2½, the seminal vesicles and the prostate were tuberculous. In a child, æt. 18 months, both seminal vesicles were tuberculous, and the epididymis on one side.

Tuberculous Disease of the Female Genitalia.—My records of this complication have been gained by the use of combined rectal and bimanual examinations during life and also in the post-mortem room. In a child, æt. 9, the Fallopian tubes were enlarged and caseous; tuberculous extension had taken place from the perineum, and they had been invaded at the fimbriated extremities. In a girl, æt. 4, the ovaries were matted to the Fallopian tubes, the extremities of which showed cavities filled with caseating material; she had tuberculous intestinal ulceration, together with tuberculous brain tumours, but no peritonitis. In a girl, æt. 7, I found an enlarged uterus, the right Fallopian tube was the diameter of a lead pencil, and there was a tuberculous lump the size of a pigeon's egg just above the top of the sacrum. I subsequently lost sight of her. A girl, æt. 7, who had tuberculous ascites, had a rounded tumour the thickness of the index finger and three inches in length, attached to the top of her uterus. This tumour subsequently disappeared. She is a healthy woman now. In a child, æt. 2 years and 2 months, there was considerable peritoneal thickening in the hypogastric region and its neighbourhood, and the left ovary, which I found to be enlarged, was attached to this. This child had tuberculous glands in the neck and an enlarged spleen also. In a child, æt. 2½, there was a tuberculous lump involving the right lumbar, iliac, and the hypogastric regions. The left ovary and Fallopian tube were healthy, but the mass had invaded the tube and ovary on the corresponding side. In a child, æt. 14 months, there was a hard lump occupying the umbilical and the hypogastric regions, and the right ovary was connected with it. In a girl, æt. 6, there was a tuberculous lump in the right inguinal, lumbar and umbilical regions, together with a typical omental thickening. The uterus was normal. Passing from it to the right was a curly tube, the size of the little finger, which could be looked down, when an oval lump was felt which was undoubtedly an enlarged ovary. The left Fallopian tube was not so enlarged, and it did not curl; its corresponding ovary was not enlarged. In a girl, æt. 3, the abdomen was lumpish, and this lumpishness extended on the right side to the inguinal region. The uterus was normal. The right Fallopian tube was the size of a penholder, and it could be traced into a thickened and hardened mass, which was possibly the tube and ovary combined, and the whole was finally lost in the abdominal lumpishness previously mentioned. In a girl, æt. 14 months, there was lumpishness in the epigastric, umbilical, hypogastric, left iliac and lumbar regions. The uterus and right ovary were enlarged. The left ovary and tube merged into the abdominal lumpishness. In a girl, æt. 1, there was lumpishness

(a) Vide Syphilis of Children. By George Carpenter, M.D. Pp. 48-49. Diagram 19.

in the umbilical, lumbar, iliac, and hypogastric regions. The right Fallopian tube was rounded and the size of a cedar pencil; it ended in the abdominal lumpishness. The corresponding ovary could not be detected. The left Fallopian tube was much larger, but not quite so distinct as that on the other side. It ended in a smooth lump the size of a walnut kernel, which was probably the ovary. The uterus was not enlarged.

I have had no experience, clinical or pathological, of primary tuberculous infection of the uterus and the adnexa in children.

Tubercle of the Choroid.—My examinations of the eyes in these cases has not been systematic, but I have made a considerable number of negative observations, and in three cases I found tubercles in the choroid. One, a female child, *æt.* 4, with caseous Fallopian tubes and tuberculous brain tumours, previously mentioned, had bright tubercles at the yellow-spot regions. Another, a male, *æt.* 2½, with intestinal ulceration and caseous mesenteric glands and miliary tuberculosis, had double optic papillitis and a large tubercle at the yellow-spot region (*vide* "Reports of the Society for the Study of Disease in Children," vol. I, plate 8, fig. 4, article "Tuberculosis of the Choroid," by George Carpenter, M.D., and Sydney Stephenson, C.M.). A third, *æt.* 4½, with intestinal ulceration, caseous mesenteric glands, tuberculous peritonitis, and tuberculous meningitis, had double papillitis and a choroidal tubercle in the right fundus oculi.

Tuberculous Meningitis.—This has not been a common complication in my experience, but two of the fatal cases developed it. In one of the cases in which it occurred the abdomen became retracted.

Unclassified.—Occasionally acute peritonitis supervenes on the chronic; this happened in one case of omental tuberculosis. Protrusion of the umbilicus is seen in some cases, as also a red blush or pink halo round it. Fæcal fistula is not a common occurrence. Enlarged abdominal veins are the rule, and occasionally there is some slight œdema of the abdominal walls.

Diagnosis.—Next arises the question of diagnosis, and, before all things, I would strongly urge the importance of *rectal exploration* associated with bimanual examination, either with or without an anæsthetic. A full account of the method will be found in "Pediatrics" ("On the Value of Rectal Exploration as an Aid to Diagnosis in Diseases of Children," by George Carpenter, M.D., June 1st, 1896, pp. 481 to 507) in "The Scalpel" (July and August, 1896), and in the *British Gynecological Journal* (May, 1896). By means of an examination conducted in this way not only can the whole of the true and false pelvis be explored with its contained organs, but in young children, from birth to 4 or 5 years of age, it is possible to examine a considerable area of the abdominal cavity outside the pelvis. Not only can abdominal lumps and tumours generally be explored with great ease by such an examination, but it is also possible to detect an amount of peritoneal thickening which would escape the most careful abdominal examination conducted in the ordinary way. In the healthy abdomen, the finger in the rectum and those on the abdominal wall should be separated by what appears to be the thickness of the abdominal wall merely, but when there is peritoneal exudation the separation of the examining fingers is often found to be more than that; thus, in the same case, one part of the abdomen may be found normal and another appreciably thickened. Comparison here comes in useful. Before such an examination is undertaken an enema should be given, the bowel cleared of its contents, and the bladder emptied; this will facilitate examination and prevent errors in diagnosis. Difficulties not infrequently occur in differentiating tuberculous conditions from other abdominal diseases. Thus a boy, *æt.* 14, was suddenly seized with pain in the abdomen, seventeen days previously, thought to be due to eating a holly-berry. For seven days and nights he suffered from pain and vomiting, and on the third day he passed a "pint of dark blood" by the bowel, and blood appeared in his stools for two succeeding days. He had a daily evacuation of the bowels until within two days of his attendance at the

hospital. He was losing flesh very rapidly. When seen he was pale, emaciated and evidently ill. The abdomen was easily manipulated. About two fingers' breadth above the umbilicus a resistant sausage-like tumour, a trifle tender on pressure, extended transversely across the abdomen. A simple soap enema was administered, and this brought away formed fæcal masses, but no blood. A rectal examination revealed nothing abnormal. His organs were healthy. For a fortnight he passed natural motions, and was for the most part free from pain. The tumour was then not so hard, or so distinctly rounded. He was emaciating. For another period of fourteen days he was occasionally sick and abdominal pains were a variable feature. His bowels acted regularly after enemata. In two or three days from then acute symptoms supervened, and it was thought necessary to perform laparotomy. An ileo-colic intussusception was found, which was reduced, but he died within a few hours. Intussusception was suspected at the time he first came under notice, but this was negated on the following grounds:—(1) the emaciation, (2) the flaccidness of the abdomen; (3) the passage of formed fæces; (4) the situation of the tumour; and the absence in it of contractions, which were carefully sought. The suspicious feature of the case was the passage of such a quantity of blood; blood in the stools is not common with tuberculous intestinal ulceration.

A girl, *æt.* 3½, who was suffering from whooping-cough and broncho-pneumonia, made satisfactory progress in regard to her illness during a period of three weeks. Then she complained of abdominal pain; she was slightly sick at times, and retched continually. Her legs were drawn up, and her face was pale. She had not passed a motion for two days, but on the day following the attack she had a slight action of the bowels attended by abdominal pain. An abdominal examination revealed a collection of several rounded masses in the abdomen, manipulation of which caused a little pain. The abdomen was perfectly flaccid. The mass was chiefly centred round the umbilical region, its lower limit being the last lumbar vertebra, and its upper was bounded by the top of the umbilical region. The tumour was semi-elastic and gave the impression of enlarged mesenteric glands. She suffered greatly from abdominal pain, and frequently vomited, but passed neither blood nor mucus by the bowel. The tumour was free from intestinal contractions. She was collapsed and lay on her back with her legs drawn up. After a rectal examination she passed a loose motion associated with some formed material. Abdominal section was performed. She had an intussusception which was limited to the small intestine. She died half an hour after the operation. In this case the acuteness of the onset, the sickness, the great abdominal pain, and the collapse were unlike tuberculous peritonitis, though the physical signs were in favour of it. Take another illustration. An infant boy, *æt.* 11 weeks, was sent to me with the following history: Since three weeks of age he had not passed anything solid from the rectum, only black fluid which was very offensive, and there had been frequent vomiting of what was stated to be fæcal matter. A fortnight before I saw him he had three fits. He was a pale-faced, poorly-nourished, weakly-looking infant, with a distended abdomen over which the cutaneous veins were very pronounced. Abdominal palpation did not afford any information so I made a rectal exploration. Situated in the right inguinal, hypogastric, and umbilical regions was a freely-movable, smooth, oval tumour, from three to four inches long and from one and a half to two inches broad, and roughly estimated about the size of a kidney—indeed, there was some suspicion as to the presence of a hiium, though I could not be certain about that. The kidneys could be felt in their normal positions. A sense of fluctuation in the tumour could not be appreciated with absolute certainty. Several enlarged glands varying in size from a pea to an almond, were felt about it, and one was behind it. Attached to it were some small nodules. To the right of the tumour the intestines felt contracted and empty rather than infiltrated with inflammatory material. Was it a tuberculous abscess? The enlarged glands were certainly sus-

picuous. An abdominal section was performed, and the tumour was found to be a mesenteric cyst firmly attached to the intestine. Two ounces of fluid were drawn from it, which contained white and red blood-corpuscles and one-twenty-fourth of albumin. Several supposed tuberculous glands were also found in the mesentery at the time of operation; but the child died, and, on post-mortem examination, the glands were found not to be tuberculous. Here is another interesting case: A boy, *æ*t. 2, who was brought to the Evelina Hospital for whooping-cough was found to have broncho-pneumonia and an abdominal tumour. A combined rectal and bimanual examination led me to form the opinion that the abdominal tumour was a horse-shoe kidney, and the child was admitted into the wards with that diagnosis. There, those in charge were equally positive it was a case of tuberculous peritonitis. The child subsequently died, and the original diagnosis was then proved to be correct. Abdominal malignant disease offers considerable difficulties to diagnosis. In malignant disease there is the same rolling-up of the omentum when this part is attacked, and tumours, similar to the touch to those met with in abdominal tuberculosis, may be felt through the abdominal walls. A girl, *æ*t. 3½, had been ailing for three months, and three weeks before she was examined her abdomen began to swell. On examination it was enlarged, measured twenty-one inches at the umbilicus, and was dull in the flanks. This dullness did not shift on change of posture. Large blue veins coursed over its parietes, which were flaccid. Lumps were detected chiefly on the right side, and here and there was a rounded and nodular mass which was situated in the right inguinal region. In the right nipple line, some little distance below the costal margin, was another rounded mass. These rounded tumours were united by ill-defined thickening. In the left iliac fossa there was a tumour the size of a walnut, which was thought to be the ovary. Behind, half an inch below the twelfth rib on either side, could be felt smooth rounded masses which were considered to be the lower ends of the kidneys. Her feet and legs were œdematous; the urine was normal. She was under treatment sixty-two days, and finally died of exhaustion. At the necropsy a tumour was detected as described arising from the right iliac fossa. The intestines were turned aside. The lower mass was found to involve the cæcum; it formed a distinct tumour there, and at the same time diffused into the adjoining mesentery. It bound down several coils of intestine, and one especially thick deposit passed towards the rectum. The upper swelling was a round, well-defined growth of the size of a small orange, situated in the mesentery adjoining the intestinal growth. The left ovary was replaced by new growth. A new growth the size of a broad bean was found in the wall of the right ventricle. The tumours were small, round-celled sarcomata. Recto-peritoneal sarcomata may also occasion difficulties, and I recently published in the "Reports" a case of suprarenal sarcoma ("A Case of Suprarenal Sarcoma," by George Carpenter, M.D., vol. II., pp. 69-73), with implication of the mesenteric glands, which could not be distinguished clinically from tuberculous peritonitis, save that it did not react to tuberculin. Further vaginal polypi (sarcomata), of which there are some few cases on record, with secondary implication of the pelvic organs and their neighbourhood, must be borne in mind.

There are cases of simple effusion into the peritoneum, no doubt, allied to the similar conditions which occur in the pleural cavities, though I cannot call to mind, in a very large acquaintance with simple pleural effusions an instance of ascites which was associated with pleural effusion. I have seen purulent peritonitis, associated with empyema, which was non-tuberculous and also simple purulent inflammation of the peritoneum, apart from empyema, of which the following case is an example:—A male infant, *æ*t. 11 months, attended at Evelina Hospital with the following history. He had suffered for fourteen days from severe abdominal pains accompanied by nausea and vomiting, and he had lost flesh. There was a remote history of consumption on the maternal side. When seen he was pale, but fairly

nourished. The abdomen was distended and prominent. Around the umbilicus was a well marked local projection which was reddened, tender to the touch, and considerably indurated. There was dullness in the umbilical, left inguinal and lumbar regions, but no fluid thrill could be obtained. The following week there was no material change, though if anything the abdomen was not quite so swollen. About a fortnight later pus appeared at the navel, and he then developed a faecal fistula, large loose yellow motions mixed with pus passing from it. He subsequently died. On opening the abdomen a large abscess cavity was seen, mostly situated to the left of the umbilicus, and stretching across the middle line to the right iliac fossa. Beneath this lay many coils of intestine, which were not matted together. On slitting up the intestines, the mucous membrane immediately surrounding a perforation which led into the abscess cavity from the upper part of the ileum was found to be perfectly healthy. The abscess evidently opened into the bowel. The organs were healthy.

I have also notes of a case of non-tuberculous peritonitis in a boy, *æ*t. 7, who, after many months of illness, associated with abdominal abscesses, which cropped up in various situations, finally made a good recovery, and has now reached a healthy adolescence.

There are other abdominal conditions which may occasionally give rise to a mistaken diagnosis. In young children the urachus and obliterated umbilical vein may be felt through the abdominal wall as indurated cords—a knowledge of this will prevent error. Ovarian tumours, cystic, malignant, and dermoids, may also prove puzzling, and rectal exploration should here prove of value. I have diagnosed an ovarian cyst with tubal implication in a child, *æ*t. 22 months, and this was verified by a surgical operation.

The full abdomen seen in infants and young children, suffering from gastro-intestinal catarrh may, on inspection, suggest the idea of tuberculous peritonitis, but a rectal exploration should here render valuable assistance and prevent any error in diagnosis. Appendicitis, which is comparatively infrequent in children has to be borne in mind to prevent mistakes; and abdominal hydatids, of which I have seen several examples in children, may occasion difficulties, but the use of the exploring needle should prevent any confusion in that direction.

Treatment.—In all the cases the usual line of treatment was adopted, and cod-liver oil, maltine, careful dieting, and rest in bed, formed the chief measures, and when the child could undertake the journey it was sent to a convalescent home in the country. Many drugs were used, chiefly arsenic, chloride of calcium, and the hypophosphites of sodium, but in several of the cases hypodermic injections of perchloride of mercury (one-thirtieth of a grain) were administered once a day, and some benefit did appear to be derived from these administrations. This treatment produced cutaneous indurations, but suppuration did not occur. Local mercurial applications, in one form or another, to the abdomen were adopted in nearly all cases. The bowels were kept relieved by enemata. Abdominal pains were treated by Dover's powder in doses of four grains or so three or more times daily for a child of five years, and so on in proportion, according to the amount of pain and the effect produced. My experience of abdominal section for this complaint has not been large, but from what I have seen I do not think it has any advantage over milder measures, and I have not been favourably impressed by it. Three cases of mine treated in this way developed a faecal fistula at the cicatrices, and faecal fistula at the umbilical cicatrix in my experience has been a rarity in children that I have medically treated. Abdominal section for the free drainage of a tuberculous abdominal abscess is, I take it, good practice; but abdominal section for tuberculous ascites is another matter. Tuberculous ascites recovers by the older-fashioned methods of rest in bed, mercurial inunction, and so forth, and inasmuch as it is not easy to see in what respect such extensive surgical treatment differs materially from the much milder form

of it in the shape of paracentesis abdominis, I prefer, when the belly is distended with fluid, to use Southey's trocar and cannula, and repeat the application when necessary.

Of fifty-four cases into whose subsequent history I made inquiries, nineteen died, ten are recorded as having recovered, sixteen improved while under treatment, and the fate of nine of them was not known. From this it would appear that tuberculous peritonitis is not infrequently cured, and perhaps more often resolves than any other form of tuberculosis; nevertheless, it must be looked upon as a very fatal disease. Treatment should rather be directed to preventive measures than to therapeutic, for at present there is more hope to be derived from the exercise of the former than by the use of the latter. In this respect the separation of the young from phthisical and tuberculous patients, a more efficient control of the milk and food supply, and the provision of a more healthy environment will occur to the minds of all.

A PERFECTED METHOD OF CHLOROFORM ADMINISTRATION. (a)

By MR. A. VERNON HARCOURT, F.R.S.

DURING many years past I have been concerned with the measurement of light, and to provide a standard light for this purpose I have used a volatile hydrocarbon, which is called pentane, as being the fifth member of the series of paraffins. In dealing with this liquid I have accidentally inhaled some of its vapour, and observed that it produced sensations similar to those caused by the inhalation of small quantities of chloroform. Since the substance is readily obtained in a nearly pure condition, it is little liable to chemical change, and is almost insoluble in water, it occurred to me that it might be serviceable as an anæsthetic. With the co-operation of Professor Gotch, the trial of its physiological properties was made by giving white rats a mixture of air and pentane to breathe. Anæsthesia was readily produced, but it was preceded by a period of excitement; the proportion of vapour to air required was rather large, involving a course of corresponding diminution in the proportion of oxygen, and recovery was slow and uncertain. The results of our inquiry formed the subject of a paper read by Professor Gotch in the Physiological Society in 1895. To form a judgment of the effects of pentane upon rats as compared with those of another anæsthetic, chloroform was administered in the same manner, and I may confess to having been a little disappointed when it appeared that chloroform was the better anæsthetic of the two.

In making these experiments it seemed desirable to find some means of regulating the proportion of air and anæsthetising gas, and of determining what the proportion was. Confining myself now to the case of chloroform, I tried a method of determination depending upon the action of a hot alcoholic solution of potash. The results were approximately right—about 95 per cent. of the chloroform, of which a weighed quantity had been brought into a flask filled with air, was represented by potassium chloride in the solution. But whatever care was taken the result was always a little too low, and I therefore sought and succeeded in finding a better method.

When a platinum wire is heated to bright redness by the passage of an electric current in a mixture of air, chloroform and steam, the chloroform is burnt on the surface of the platinum by the oxygen in the air, and the chlorine, which is probably formed in the first instance, reacts, also under the influence of the heated wire, with the steam forming hydrochloric acid and oxygen.

(a) Read at the meeting of the Society of Anæsthetists, March, 1903.

A small quantity of water placed in the flask containing the mixture of air and chloroform serves both to supply steam when the bottom of the glass is heated, and to dissolve the hydrochloric acid which is formed. After twenty minutes the operation is completed, and it remains only to determine the amount of hydrochloric acid in the flask, which may be done by means of a standard solution either of silver nitrate or of alkali. A full account of this method, and the record of the testings with weighed amounts of chloroform, by which its trustworthiness was established, is given in the "Transactions of the Chemical Society for 1899."

In the same paper there is also described a method for charging a current of air with a proportion of chloroform vapour, which might be fixed at any desired limit. This method consisted in sending a stream of air through a mixture of alcohol and chloroform and then through water. If the mixture contains only a small proportion of chloroform, then but little chloroform evaporates into and mixes with the air if the proportion of chloroform in the liquid is larger the amount that evaporates is larger also. By passing the mixture of air with the vapours of alcohol and chloroform through or over water the alcohol is removed, and only air and chloroform pass on in a proportion determined by that of chloroform and alcohol in the liquid mixture. That the liquid used for diluting chloroform in order to diminish its rate of evaporation should be itself volatile is advantageous, since, when the quantity of both liquids diminishes as evaporation proceeds, the composition of the mixture remains more nearly constant than if only one was evaporating.

After writing this paper it occurred to me that a method might be made on the same principle for the administration of chloroform as an anæsthetic. In order to provide for its administration in sufficient quantity, and with a minimum respiratory effort, I changed the form of the apparatus.

If air travels over a liquid for a sufficient distance saturation is complete, and the resistance is far less than if the air bubbles through. I had found by trial of various proportions that a mixture of eighty parts of alcohol by weight with twenty of chloroform yields, when air is passed over it, a mixture of ninety-eight volumes of air with two of chloroform vapour. I had found, and subsequent experience has confirmed the conclusion, that 2 per cent. of chloroform is the maximum amount ever required in producing anæsthesia. To reduce this proportion to any smaller proportion that may be desired I made an arrangement of stop-cock and valves, by which the 2 per cent. mixture may be diluted to any amount with pure air, a pointer moving on a scale indicating the percentage thus produced.

This apparatus was tried at the Oxford Infirmary by Mr. Parker, a surgeon who had had large experience of anæsthetics during the South African War. The tank filled with water, which holds the two boxes containing respectively alcohol mixed with chloroform and water, was supported on a staging beneath the trolley on which the patient lay, and the face-piece was connected with the outlet of the apparatus by caoutchouc tubing.

The management of the amount of chloroform administered presented no difficulty, and the result was satisfactory, but Mr. Parker represented to me that for ordinary medical use a portable apparatus was necessary. For this purpose the limitation of chloroform by dilution had to be given up, and I substituted for it a limitation of the surface of chloroform from which evaporation takes place. After trying vessels of various size, I found that air passed at the ordinary rate of human respiration through the upper part of the bottle containing chloroform, whose diameter was about $1\frac{1}{2}$ in., took up 2 per cent. of chloroform. This proportion does not vary as might be expected with the rate at which air is drawn through. When the air enters the bottle slowly it passes from inlet to outlet without complete admixture with the air and chloroform lying over the surface of the liquid, and thus a

smaller quantity of air is mixed with a smaller quantity of chloroform. On the other hand, when air enters more rapidly it blows upon the surface of the liquid and causes more rapid evaporation, and thus a larger quantity of chloroform.

▶ The original instrument had the form of a straight stem to which the face-piece was attached, with branches connecting through a stop-cock with this stem, and at their other end with two valve-chambers, one opening into the air, the other attached to a small Woolfe's bottle holding chloroform. The handle of the stop-cock terminated in a pointer moving on a divided arc. According to the position the stem was connected either with one branch or the other, or partly with both. A prolongation of the stem upwards ended in another valve-chamber which allowed passage to expired, but not to inspired air.

Since the amount of evaporation depends not only on the area of liquid from which evaporation is taking place, but also upon the temperature of the liquid, the operator must be provided with some ready way of observing temperature. A thermometer cannot be read very quickly, and its insertion would require the provision of a third tubule. Specific gravity bulbs are easily seen and answer the purpose well, since the density of chloroform changes rapidly with its temperature.

By providing two bulbs, one of which is between floating and sinking when the temperature of the chloroform is 15° C. (59° F.), and the other when the temperature is 12.5° C. (54.5° F.), and placing these in the bottle with the chloroform, it can be seen whether the temperature is above 15°, for then both bulbs sink, or below 12.5°, for then both bulbs float. The temperature should be maintained, so far as is possible, between those temperatures, and when this is so, one bulb is floating and the other sunk.

Since anaesthetising and operating rooms are kept at much higher temperatures than 59° F., I used at first bulbs which were adjusted for several degrees higher; but the cooling of the chloroform by evaporation is so great that frequent applications of the hand to the bottle were needed to maintain the higher temperature. Also the proportion of chloroform with a bottle of the size I used was, at a higher temperature, rather more than 2 per cent.

I have made several other changes in this inhaler, to which I propose to give the name of chloroform regulator, since I read a paper on the subject to the Royal Society.

To enable the face-piece to be placed in any position, I have divided the stem into two parts by a cross-branch, and have provided each part, as well as the cross-branch, with swivel-joints. The longer piece of caoutchouc tubing connecting the chloroform bottle with one of the valve-chambers, which allowed the bottle to retain a vertical position when the stem was inclined, is now shortened, since the stem can be held upright. The upper valve-chamber has been removed and the valve transferred to the face-piece. This has the advantage of making expiration easier, and limiting it to the face-piece, so that none of the patient's breath passes into the body of the instrument. The bottle has been made slightly conical, enlarging downwards. As the chloroform evaporates the interval between the surface and the air-inlet necessarily increases, and this is balanced by an increase of area.

The valve consists of discs of celluloid held in position by a short neck or continuous strip of the same material, the end of which is fastened down. By cutting this neck of a suitable width, the spring, which holds down the disc against the tube which it covers, may be made just sufficiently strong to support the weight of the disc in an inverted position.

The movement of these valves gives useful information. That on the face-piece shows clearly whether respiration is full or regular, those connected with the two branches show, by the height to which they are raised, how much of the 2 per cent. mixture is being inhaled, and with how much air it is being diluted. The proportion is also shown by the position of the

pointer on the divided arc. For example, if it is in the middle, equal quantities are being inhaled of air mixed with 2 per cent. of chloroform and of pure air, that is to say, the mixture being inhaled contains 1 per cent. of chloroform. From any other position of the pointer upon the scale the percentage of chloroform which is being administered can be read off.

I have been present at four or five operations at University College Hospital, and, so far as I could judge or learn afterwards, the assistant to whom the management of the regulator was committed found no difficulty in maintaining the desired degree of anaesthesia. The proportion of chloroform required to produce anaesthesia in from five to ten minutes was, with adults, between 1 and 1.5 per cent., and for its maintenance subsequently between 0.5 and 1 per cent. I think it possible that the actual figures should be lower than these, some uncertainty arising from imperfect fitting or occasional displacement of the mask. But here I am on unfamiliar ground, and I hope an account which will be much more trustworthy of the use of the regulator and its advantages, as compared with other apparatus or methods for administering chloroform, will be given to the Society by its President, to whose encouragement during the past two months I am greatly indebted.

THE VALUE OF ARTHROTOMY IN THE TREATMENT OF CERTAIN JOINT LESIONS. (a)

By P. LOCKHART MUMMERY, F.R.C.S.Eng.

MANY cases of what may be called subacute septic joint lesions follow or occur contemporaneously with septic infections—*e.g.*, influenza, scarlet fever, measles, or pneumonia. Other cases occur after some septic lesion, such as a whitlow, or oral sepsis; and the organism has been demonstrated in the joint fluid. Certain cases known as chronic rheumatism, or rheumatoid arthritis, may be really pyæmic in origin, and comparable with gonorrhœal arthritis. The fineness of the capillaries in the synovial membrane, or some antecedent trauma, may determine the localisation in the joint of organisms circulating in the blood. Drs. Poynton and Paine have produced in rabbits a subacute or chronic arthritis by the intravenous injection of a diplococcus. There are two types of septic arthritis following infection of the blood—the acute and the subacute—sometimes called pyæmic arthritis, but not part of a general pyæmia. The primary focus from which the blood is infected is often insignificant.

Acute septic arthritis is generally the result of direct infection from a wound, and is not common from blood infection, except as part of a general pyæmia. It does occur, however, as in the following case: In one patient, *æt.* 21, who was out of health, a slight abrasion of the finger caused a pustule. Five days later he felt a sudden pain in the left ankle. Four days later he was admitted to hospital, very ill, with a temperature of 102°, and the left ankle much swollen and inflamed, and evidently containing pus. The finger had nearly healed. Incisions were made into the ankle, which was treated with a continuous water-bath. The incisions had to be opened again a week later, and ultimately septicæmia rendered it necessary to amputate. After this the patient recovered. There was no history of traumatism, no previous joint disease, and no general pyæmia. The infection seemed to come from the finger; and

(a) Read before the Harveian Society of London, March 5th, 1903.

earlier opening of the joint would probably have saved the limb. In such cases the occurrence of pus should not be waited for. For although many patients may recover without opening the joint, the risk of delay is infinitely greater than that of early incision. All that is said in favour of early operation in septic lesion of the peritoneum applies with equal, if not greater force to septic joint lesions. It seems to be thought that the best that can be expected in septic joint lesions is a stiff joint. But with early opening, irrigation and draining, the results would be much better.

Subacute septic arthritis may follow sepsis after pregnancy or the acute fevers or gonorrhœa. Treated by rest and lotions these cases show frequent formation of adhesions, or recurring attacks of synovitis; whereas opening the joint and washing it out gives excellent results. The joint lesions are often mistaken for acute rheumatism, but the condition does not react to salicylates. The joints should be opened, adherent lymph removed, the cavity washed out, and the wound closed. The process greatly reduces the time during which the patient is incapacitated, and prevents further damage to the synovial membrane. The patient is usually able to use the joint freely in ten days or a fortnight after the operation.

In gonorrhœal arthritis there is a marked tendency to the formation of adhesions, and recovery is very slow. But, with opening and washing out the joints, especially if done early, the disease usually rapidly subsides.

In the more chronic cases of septic joint, massage and movement should first be tried. If unsuccessful, arthrotomy should be performed, and the joint irrigated. In many cases in which firm fibrous adhesions have formed, opening the joint and dividing the toughest bands is often better treatment than attempting to break down the adhesions by force. Arthrotomy again is the best treatment where hæmorrhage has occurred into a joint as the result of injury.

It is only fair to mention the use of arthrotomy by Dr. O'Connor, of Buenos Ayres, in cases of acute rheumatism. It is claimed that this treatment lessens the duration of the disease, and the liability to cardiac lesions. Dr. O'Connor believes that the joints form the infected foci from which the heart is affected. In this country, where rheumatic fever seems to react to the use of salicylates, it seems difficult to believe that arthrotomy is needed.

With regard to the operation, in the case of the knee-joint, the best incision is a vertical one on the outer side of the joint one and a-half to two inches in length. In this way the scar is less likely to become adherent to the bone. In the ankle-joint a vertical incision should be made just behind the external malleolus. Through the incision the joint fluid is evacuated, some being kept for bacteriological examination. The joint is then thoroughly washed out with sterilised hot water, or saline solution, any adherent lymph being carefully removed. Antiseptic solutions are probably useless, and may injure the synovial membrane. The joint should next be dried with aseptic sponges, and the edges of the wound closed, the edges of the synovial membrane being well approximated. It is often unnecessary to put in a drain, except in acute cases. If drainage is necessary, gauze wicks are best. Tubes are apt to be nipped between the bones, while gauze can be more easily placed in the part of the joint where drainage

is required, and a depressed scar is less likely to result. The gauze can be removed in from twenty-four to forty-eight hours. To drain the knee-joint efficiently the patient should be placed in the prone or the lateral position, so that the incision is at the lowest point. In bad cases of septic arthritis of the knee, where drainage is difficult or the symptoms are not relieved, it is well to expose the joint by dividing the patella transversely. After dealing with the synovial membrane, proper drainage is provided and the patella wired. No splint should be applied, as a slight amount of movement assists drainage. After the wound is dressed firm pressure should be applied by cotton wool to prevent the accumulation of fluid. The joint should be moved daily from the day succeeding the operation, voluntary movement being preferable. Massage may be necessary in the more chronic cases when the muscles have become wasted.

I regard the operation as simple and practically free from risk, the open method being infinitely superior to aspiration. Before closing the wound it is important that all bleeding should be stopped.

The Out-Patient Departments.

TABES DORSALIS WITHOUT ATAXIA.

BY C. H. CATTLE, M.D., M.R.C.P.,

Assistant Physician to the Nottingham General Hospital.

A MAN, *æt.* 49, came with neuralgia in the head and stabbing "lightning pains," not only in the legs but in other parts of the body. He had influenza five years ago. His worst trouble, which has been persistent for the last two years, is a fixed dull pain running round the right half of the body at the level of the twelfth rib, occupying pretty correctly Head's twelfth dorsal area. This is in all probability a "root-pain" due to sclerosis involving the posterior columns in the lumbar enlargement which is, of course, in close proximity with the dorsal portion of the cord. So this symptom, apparently isolated, becomes of importance in diagnosis when taken in connection with some other signs I am just about to mention. It is noticed, for instance, that the left eyelid droops a little and that the eye is not so well opened as the right. Indeed, the patient says that a week or two ago the left eye was still more closed than it now is. Here then is another sign of early tabes, *viz.*, temporary paralysis of one or more of the ocular muscles. Another symptom he mentions, apparently of a casual nature:—Three months ago while at work he was seized with a sudden sharp pain in the abdomen, which culminated in an attack of diarrhœa, the effects of which caused him to lie up for a fortnight. Very likely an "intestinal crisis," we say to ourselves! And indeed the diagnosis is no longer in doubt, for we see the pupils are small (spinal myosis), and do not contract to light, but contract consensually when the patient converges to look at a near object. Finally no amount or degree of tapping avails to procure the knee-jerk.

The patient can, however, stand quite steadily with toes and heels apposed and eyes shut (absence of Romberg's sign); also he walks quite steadily across a room with closed eyes, does not bring his feet down with a slam, or feel as if walking on wool. He made no complaint of vision, but I was particular to notice that the optic discs were quite normal, for I was reminded by a medical man who spoke when the patient was shown at a medical meeting that cases which develop early optic atrophy are late in developing ataxia. Now ataxia depends, to a great extent, upon degeneration of the sensory fibres of the posterior columns of the spinal cord, which chiefly convey impressions of muscular sense, such as position, weight, tension, &c. Absence of ataxia in such a case as this would not negative the opinion that the posterior columns are diseased; it only shows that the sensory path is not, as yet, sufficiently involved to produce the symptom. Cases of tabes are occasionally arrested at any stage, but there is every probability that this man will

eventually become ataxic. He denied ever having had syphilis. There is a strong disposition on the part of our best modern authorities to attribute both tabes and general paralysis to syphilis. Undoubtedly syphilis can be proved in the case of a large majority.

Treatment.—The patient had heard wonderful accounts of the effects of the X-rays and requested to have them. I consented, knowing the obstinate character of the pain (for which he chiefly sought relief), and being aware also that the pain of cancer even, although the disease may not have been otherwise influenced, has been eased by this treatment. The first effect of the X-rays was to give great relief, perhaps partly owing to mental influence, just as a few years ago we used to read glowing reports of improvement after "suspension." But within a month the pain was as bad as ever. A second month of treatment was advised, during which an X-ray burn or "reaction" occurred. By this is meant an inflamed, reddened and discharging surface, in this case as large as the hand, on the patient's flank. The effect is very similar to that caused by blistering, and the man said it had given him more relief than anything. I have not seen him since, but have heard that he still has the pain, though it is not so severe.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MARCH 13, 1903.

MR. HOWARD MARSH, F.R.C.S., President, in the Chair.

MR. T. S. ELLIS (Gloucester) read a paper
ON SKIN-SLIDING

as a means for preventing and for removing cicatricial deformity.

The process of skin-sliding or stretching was devised by the author in the belief that when the skin in the neighbourhood of a cicatrizing wound is made to slide freely and all adhesion of the cicatrix at the margin of the wound to the tissues beneath is prevented, the contraction of the cicatrix, acting on the skin, will draw it towards and over the area of the wound, interstitial growth in the extended skin compensating for the extension it has undergone. Lantern slides were shown of a case of severe burns involving destruction of both ears and of the whole of the integuments from a line across both cheeks and above the chin down to one just above the clavicles. Here the principle had been applied, but only to the lower margin of the neck wound. At the daily dressing the skin was picked up at and below the margin of the wound with the finger and thumb and gently drawn outwards. The wound healed along the line of the lower jaw, the neck being covered with normal skin, having a very sharply defined margin, while above, on the upper side of the same wound, where healing had been allowed to proceed without disturbance, large masses of keloid extended up the cheeks. Keloid also formed on the other wounds. A tattoo-mark is now at a much greater distance from the margin of the skin than when it was first made. This and a similar change sometimes seen in the position of stitch-marks is suggestive of growth at and from the margin of the skin towards the wound, even if there be also interstitial growth in the skin at a distance. Moreover, if an attempt be made to cover a granulating wound with skin derived from the margin, and this margin consists of skin mixed up with old cicatrix tissue the result is a failure. If the supply of new skin were entirely due to the traction influence of the cicatrix with interstitial growth in the skin at a distance, then presumably the traction influence would be the same whether the marginal skin were free from cicatrix tissue or not. On the other hand it is easy to imagine that the difference would be material if there be really growth at the margin. The keloid on the face has been partially removed by excision, and when the skin has been persistently stretched by the use of cicatrix calipers and by drawing it outwards with the hand, compelling it to freely slide, any remaining scar tissue can, if necessary, be excised. Then even in an extended

position, there will be no tension on the cicatrix which, being in a line of folding when the skin is relaxed, will have the full benefit of complete coaptation in the position of rest. Thus a minimum of scar may be predicted. For the effacement of a cicatrix of any kind not only is the attainment of freedom from attachment indicated, but also such mobility and such redundancy of skin around it as shall, for a time, give freedom from even the small degree of tension to which, under ordinary conditions of skin, the cicatrix would be liable. This indication may often be completely fulfilled by persistently sliding the adjacent skin towards the cicatrix and using the skin (made redundant) as a handle wherewith to lift the cicatrix from its attachment.

Mr. BARKER referred to a valuable report which had been published in their "Transactions" on the behaviour of keloid, in which it was pointed out that keloid sometimes underwent spontaneous cure. He mentioned a case of his own in which skin grafts had been followed by such rapid growth of keloid that it was thought to be sarcoma, though the subsequent history showed that this was not the case. Obviously, however, they required to know more about the natural history of keloid before they could safely accept any alleged curative action thereon.

Dr. W. H. B. BROOK asked what was the exact manner of picking up the skin and for what period of time daily it had to be picked up.

Mr. ELLIS, in reply, said that in the interval that elapsed before keloid disappeared the skin around it had time to develop. In his mind the whole question was whether the skin around had become freely movable. All that was required was to pick up the skin with the finger and thumb for a minute or two daily.

Dr. W. H. B. BROOK, Surgeon to the Lincoln County Hospital, showed a case of

TOTAL PARAPLEGIA DUE TO CARIES OF THE MID-DORSAL VERTEBRÆ, FOR WHICH THE OPERATION OF COSTO-TRANSVERSECTOMY WAS PERFORMED WITH COMPLETE RECOVERY.

Arthur A—, a clerk, æt. 17, was admitted into the Lincoln County Hospital on September 22nd, 1902, suffering from angular curvature of the spine of one year's duration, for which he had worn a plaster jacket. During the previous four weeks he had gradually increasing loss of power in his legs, with incontinence of urine. When admitted he presented well-marked angular curvature, the sixth and seventh spinous processes being the most prominent. There was no tenderness, nor were there any signs of any collection of pus. There was well-marked girdle sensation at the level of the epigastrium, with great impairment of sensation below this level. The legs could be moved but not well; the knee-jerks were exaggerated, and there was incontinence of urine. For six weeks he was treated by extension applied to each leg, but his condition became steadily worse, the paraplegia becoming complete, with incontinence of urine and feces, and the appearance of bedsores in spite of the greatest care. A skiagraph showed blurring in the region of the seventh and eighth dorsal vertebrae, confirming the diagnosis that tuberculous matter was present. On November 8th, the operation of costo-transversectomy was performed, the right transverse process of the eighth dorsal vertebra being cut down upon and removed together with the head and neck of the eighth rib, so that access was obtained to the seat of the disease, and the broken down bodies of the vertebrae were carefully scraped away with a specially designed curved sharp spoon, care being taken not to wound the dura mater or the pleura. The wound was drained, injected with iodoform emulsion containing 1.40 carbolic acid, and tightly packed with iodoform gauze. The extension was continued. Sensation began to return on the following day, and movement on the day after. At the end of three weeks sensation was perfect and movement good, but it was seven weeks before the patient regained perfect control over the bladder and rectum. The drainage-tube was discontinued on January 8th, the wound was healed by January 25th, and on February 15th the patient was able to sit up, after having been fitted with a steel spinal support. He is now able to walk quite well.

Mr. JACKSON CLARKE showed the skiagram of a lady, *æt.* 47, seen in consultation eighteen months ago, when she complained of girdle pain followed by paraplegia and sensory and motor paralysis. They decided to perform laminectomy, but after doing so, in passing the aneurysm needle backwards, he opened up an abscess cavity, which he evacuated and washed out. Muscular power subsequently gradually returned. Six months later an abscess formed under the lateral scar, which was opened and left an aseptic sinus. He thought an abscess in this situation could best be opened by a lateral incision, and he admitted that they might have dispensed with the laminectomy. He also referred to several other cases in which he had operated in this way. Keetley's method of trephining was, he thought, dangerous, in that it exposed the cord to serious risk of damage.

Dr. BROOK, in reply, said that on the whole he preferred straight spoons to curved ones.

Mr. STEPHEN PAGET read a paper on TWO CASES OF PROLAPSE OF THE BOWEL, AND A CASE OF PROLAPSE OF THE UTERUS TREATED BY THE INJECTION OF PARAFFIN UNDER THE MUCOUS MEMBRANE.

The first case was that of a man, *æt.* 65, who in 1897 had undergone excision of the rectum for cancer. Ever since the operation he had suffered from prolapse of the bowel with loss of control, and had been compelled to wear a rectal plug. On January 15th paraffin was injected into the prolapse, forming two hard round nodules under the mucous membrane, so that the opening into the bowel was closed by a sort of valve. Since then there has been no prolapse; the patient had left off his plug and had kept perfectly clean. The second case was that of a patient of Dr. E. Lycett Burd, of Shrewsbury. She was *æt.* 70, and had suffered prolapse of the bowel for twenty-two years, and had undergone five operations. Prolapse occurred on the very least effort, and if the motions were loose she had no control over them. On February 15th paraffin was injected under the mucous membrane, forming a hard collar round more than half of the bowel: this produced a great improvement, but there was still a very slight prolapse at times. On March 1st a second injection was made, and the opening into the bowel was also narrowed by Mayo Robson's incision and suture. This second operation was followed by some severe pain, but no prolapse has occurred since it was done. The third case was that of a woman, *æt.* 63, who for twenty-eight years had suffered prolapse of the uterus. An operation (? Alexander's operation) had been performed fourteen years ago. The prolapse now occurred even when she was in bed, if she only coughed or turned over. By day she supported it with a napkin. The vagina was so greatly dilated that it would not retain a pessary, and there was complete prolapse of both walls and of the cervix, which was greatly enlarged. On February 25th paraffin was injected in various directions under the mucous membrane of the vagina, mostly in the posterior wall, and under the mucous membrane of the cervix. Since this injection she has had no prolapse, not even when she has strained at the closet, or has borne down forcibly in the erect posture. The cervix is high up, both walls of the vagina are indurated, and the recto-vaginal septum is about half an inch in thickness. Mr. Paget said that he brought these cases thus early before the Society because he felt sure, from his experience of the use of paraffin in forty cases of sunken nose, that the good results in these cases of prolapse would be well maintained. If it were at any time necessary to add a little more paraffin this could easily be done.

Mr. BARKER mentioned one case of prolapse in which he had adopted this method for incontinence with complete success. He used a mixture of soft paraffin and olive oil.

Dr. ROBINSON confirmed the excellent result obtained in the author's third case, but suggested that the operation would hardly be suitable in a woman who was still capable of child-bearing, and in view of the narrowing of the vagina it might conceivably interfere with coitus.

Mr. PAGET, in reply, said it would be necessary for him to go thoroughly into the history of the operation in

order to find out exactly what the risks were in regard to embolism. Two cases had been reported, but under circumstances which obviated any surprise at the occurrence. He protested that his experience of the method in this connection had been very small and the results were necessarily very uncertain although so far in favour of the operation.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, MARCH 5TH, 1903.

The President, DR. W. WINSLOW HALL in the Chair.

MR. P. LOCKHART MUMMERY read a paper on "Arthrotomy in the Treatment of Certain Joint Lesions," an abstract of which will be found on page 266.

Mr. PHELPS, having worked for the last three years with Dr. O'Connor, was able to speak very favourably of arthrotomy and irrigation in septic and gonorrhœal arthritis. As regards the treatment of acute rheumatism by arthrotomy, doubt has been thrown on the nature of Dr. O'Connor's cases; but Mr. Phelps could only say that those he saw presented all the clinical features of the disease. They appeared, however, to be less influenced by salicylates than cases in England. The amelioration of constitutional symptoms following the disease was very marked, and the patient was usually able to leave the hospital within fourteen days. In no case had a recrudescence of the disease or endocarditis occurred. Of course, it would be absurd to treat every patient, especially children, by arthrotomy; but there occur cases in which the disease for a time is localised in a few joints, especially those of the lower limbs. In these cases the treatment is well worth consideration.

Dr. SYDNEY PHILLIPS said that it was never claimed that salicylates absolutely prevented cardiac disease; Arthrotomy might; but he had no experience, and therefore no opinion in the matter. As regards septic joints, he thought they were now very rare as a sequel to the infectious diseases. There was, in fact, very little evidence of actual arthritis after the exanthemata. Scarlet fever occurring in patients with joint disease does not affect the course of that disease.

Dr. JOHN BROADBENT inquired what was the age of the patients on whom arthrotomy for acute rheumatism was performed. In adults the joints are usually attacked, while the heart frequently escapes. In children, on the other hand, the heart and pericardium may be repeatedly attacked with little or no obvious affection of the joints. He did not consider it proved that the joint affection invariably precedes cardiac lesions. He would be glad to know if a bacterial examination was made in Dr. O'Connor's cases.

Dr. S. VERE PEARSON had been struck by the number of patients who suffered from acute or subacute arthritis of a doubtful origin. The difficulty at present is to say which cases are suitable for surgical treatment. He considered the exploring syringe useful for withdrawing fluid from the joints for bacterial investigation. He could see little advantage in arthrotomy for acute rheumatism. The type of the disease differed according to locality, and perhaps in Buenos Ayres was more amenable to surgical than to salicylate treatment. He did not believe the heart lesion to be secondary to the arthritis, for there is evidence to show that the endocarditis is present simultaneously with the active synovitis.

Mr. PHELPS replied that in Dr. O'Connor's cases bacteriological examination had unfortunately not been properly carried out.

Mr. LOCKHART MUMMERY had found records of joint lesions after measles and pneumonia, and in some cases of influenza bacteria had been found in the joints. Staphylococci had been found in the majority of septic joints, sometimes associated with other organisms. Aspiration he hardly thought worth while, as an anæsthetic would be required, and the joint might as well be opened. A bacteriological examination of fluid withdrawn from the joint would take time, and prevent the good result of early operation—if the result were waited for.

LARYNGOLOGICAL SOCIETY OF LONDON.
MEETING HELD MARCH 6TH, 1903.

DR. P. MCBRIDE, the President, in the Chair.

DR. A. BRONNER showed a microscopic specimen of columnar-celled carcinoma of the naso-pharynx from a case which had been under observation for four and a half years.

Sir FELIX SEMON remarked that it was a well-known experience that malignant disease in the nose and naso-pharynx usually pursued a slow course.

Dr. W. H. KELSON showed (1) a man showing dislocation of the bones of nose due to polypi, and (2) bleeding polypus in a girl, with microscopic section.

Dr. H. TILLEY showed a case illustrating the result of operative treatment of adhesion of the soft palate to the posterior pharyngeal wall in tertiary syphilis.

Mr. F. J. STEWARD showed a case of clonic contraction of the palate, adductors of the vocal cords and certain other muscles. The patient had a staggering, reeling gait and slightly increased knee and patellar reflexes, but no other signs indicative of lesion of the nervous system.

Sir FELIX SEMON considered the gait was not typically tabetic, and suggested the probability of cerebellar tumour.

Mr. CRESSWELL BABER showed (1) a tumour of vestibule from a woman, æt. 26, with microscopic section, and (2) a tongue depressor for exposing the tonsil.

Dr. D. VINRACE showed a case of lupus (?) of nose and face in a woman, æt. about 60.

The case was discussed by Drs. Fitzgerald Powell, Wm. Hill, Dundas Grant, and Mr. F. H. Westmacott.

The PRESIDENT showed a case of anosmia in a man, æt. 39, who had lost the sense of smell in the beginning of 1901, with a view of obtaining opinions as to diagnosis and also for suggestions as to treatment. The principal feature of interest in the case was the intermittent character of the anosmia.

The case was discussed by Mr. Baber, Drs. de Havilland Hall, D. Grant, J. Donelan, L. H. Pegler, and P. Watson Williams.

Dr. H. L. LACK showed various microscopic specimens and the case of a man (shown at the January meeting) who was suffering from spastic aphonia affecting the speaking, but not the singing voice. He had now completely recovered his power of speech.

Dr. T. DONELAN showed a case of perforation of the nasal septum (? trauma or syphilis).

THE OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

GENERAL MEETING HELD MARCH 2ND, 1903.

DR. URBAN PRITCHARD in the Chair.

RESUMED discussion on
TUBERCULOSIS OF THE EAR, NOSE, AND NASO-PHARYNX.
(See MEDICAL PRESS, February 25th, 1903, pages 192-3.)

Mr. RICHARD LAKE described two cases in which, although there was well-marked tuberculous disease of the tympanum and aural accessory centres, yet the pus which flowed down the Eustachian tube had not infected the larynx. He thought that cases of tubercle of the middle ear coming on during pulmonary tuberculosis were far commoner in this country than on the Continent. He would not advise grafting after operating upon a mastoid for tuberculous disease because of the risk of shutting in tubercular granulations.

Dr. DUNDAS GRANT quoted a case showing how insidious may be the origin of tuberculous disease of the middle ear, even in a very robust-looking individual. The case was probably one of direct infection from a female suffering from advanced tuberculosis of the lungs. He warned against the idea that all cases of sudden discharge not preceded by pain were of tuberculous origin. He favoured operating by stages in the case of advanced tuberculous ear disease occurring in an otherwise tuberculous subject.

Mr. C. H. FAGGE thought that many of the large sequestra which had been brought before the Society were tuberculous.

Replying to the discussion, Dr. Wingrave said that the difficulty of finding tubercle bacilli in aural discharges was often due to the thoroughness of local treatment. He discussed the origin of their acid-fast property. He had only found tuberculous lesions in 1% of many adenoid growths which he had examined, but tubercle bacilli were present in greater proportion on the surface of these growths. Strong evidence of direct infection of the middle ear by way of the Eustachian tube was also adduced. The extensive mastoid necrosis in children was not surprising owing to the late development of the air cells in that process, while the proclivity of the stapes to tuberculous disease was possibly due to its peculiar development round the stapedial artery and its later ossification compared with that of the other ossicles. Cases were quoted showing the excellent results following combined local and constitutional treatment.

In reply, Dr. JOBSON HORNE still maintained that the absence of pain in many tuberculous cases of ear disease was due to the chemical action of micro-organisms. Mr. Ballance had also upheld the view that in primary tuberculosis of the ear it was better to remove the infected glands first, and later, having thus localised the disease, to attack the bone lesion. Dr. Whitehead had shown from his hospital statistics that in the primary cases, death was commonly due to meningitis. Dr. Horne, referring to bovine tuberculosis as a cause of bone tuberculosis in man, said that he thought it would eventually be shown that the danger of infection arose solely from already infected human beings. He thought it would be unwise to depend on the sense of smell in the diagnosis of tuberculous ear lesions, however characteristic the factor of the pus might be in these cases.

Dr. MILLIGAN, referring to the question of tuberculous infection of adenoids and their influence upon tuberculosis of the ear, said that an adenoid vegetation might act merely as a culture bed without itself becoming tuberculous at all, and the infection might then pass on to other organs. He thought tuberculous cases should be sent to the southern, as opposed to the northern or eastern, seaside resorts. The discussion had shown that primary tuberculous disease of the ear was more common than had been supposed; and hence the primary focus of the disease should be removed and the whole question of operation should be determined by the general condition of the patient.

Dr. MILLIGAN thought that the finding of tubercle bacilli was of especial value in reference to prognosis in aural tuberculosis. He also advised grafting in tuberculous cases because the disease did not often invade the bone deeply, and it was quite possible to eradicate it in the majority of cases. In his experience the stapes was seldom thrown off as a sequestrum in non-tuberculous cases, the reverse being the case in tuberculous disease.

Dr. C. H. Fagge, Mr. A. H. Cheatle, Dr. Wm. Milligan, Dr. Horne, and Dr. J. Kerr-Love showed other specimens, micro-photographs and skiagrams of tuberculous disease of the middle ear, and the meeting adjourned.

SOCIETY OF ANÆSTHETISTS.

MEETING HELD MARCH 6TH, 1903.

MR. WALTER TYRRELL, President, in the Chair.

MR. A. VERNON HARCOURT, F.R.S., read a paper on his new Chloroform Regulator, which will be found on page 265.

The PRESIDENT, in introducing Mr. Vernon Harcourt, referred to the report of a paper read by the author before the Royal Society on the "Percentage Dosage of Chloroform." Since then he had been invited to become a member of the committee of the British Medical Association on the Dosage of Chloroform, and

had asked that committee to allow him to show his apparatus, and read a paper on the "Percentage Dosage of Chloroform" before the Society of Anæsthetists.

In opening the discussion, the PRESIDENT recalled that half a century ago Dr. Snow had invented an inhaler with two orifices through which the inspiration was made; through one of these the inspired air passed over chloroform, and the other was an inlet for pure air, and by slowly diminishing the size of the latter, more and more of the inspired air passed over the chloroform until the desired anæsthesia was produced. This is exactly what Mr. Harcourt's apparatus did, but nobody before has been able to show approximately what percentage of chloroform was being inhaled at any given moment. Mr. Glover had given them a percentage of chloroform, but without any accurate means of regulating it. Junker's inhaler, with its many modifications (made mostly by members of this Society), and various other methods, all tended towards the desired end of regulating the quantity of vapour inhaled, but it was only now that they had learned what the percentage really was. He gave notes of a few cases in which he had used the instrument. He said that a child, æt. 8 years and 3 months, had been satisfactorily anæsthetised for an elbow operation and glands of the neck without ever exceeding 0.5 per cent. of chloroform. He had had several adult cases, including iridectomy for glaucoma, removal of breast, appendicectomy, &c., which had not required more than 1 per cent., and in no case had any patient of his required the maximum amount or 2 per cent. In one case pallor and failing pulse occurred while using 1.4 per cent., which is an instance of what cannot be too strongly insisted on, viz., that a percentage only sufficient to produce anæsthesia is dangerous to a certain number of individuals. The most striking thing about the administrations was the greatly diminished amount of excitement, in fact, in several cases this was entirely absent.

DR. DUDLEY BUXTON said they had before them that night an actual dosimeter of chloroform. In the apparatus before them they had certainly a means by which they might accurately and definitely know percentages of chloroform. There was one idea they, as practical men, had to dispute, *i.e.*, that a 2 per cent. of chloroform was capable of carrying them through all exigencies. Affairs such as they had to face to-day in the operating theatre were very different from those of fifty years ago. In those days operations which required a death-like stillness were not performed, and absolute quietness of the patient was neither asked nor expected. Not only were they now asked to render the patient anæsthetic, but to push necrosis to such an extent that vitality was distinctly lowered. They were asked to act on the medulla oblongata, and things had to be pushed thus far in order that the surgeon might carry out his operation. They (the anæsthetists) had to do as they were told. He was quite sure that 2 per cent. would not carry them through all operations. Would it not be possible to alter the apparatus in order to provide a 4 per cent. vapour if such were required? The experience he had had with the apparatus had agreeably surprised him, more particularly as he was somewhat averse to new chloroform-regulating inhalers, as so many had been failures. None of them expected to give chloroform with absolute safety, and most of the apparatuses patented had fallen short in some important detail. With Mr. Vernon Harcourt's he had expected to have moderate success, but the success obtained had exceeded his expectations. It produced a quiet anæsthesia, with little or no struggling; the patients had gone under with a low percentage beginning with .5, sometimes .25 per cent. In a case of abdominal section for gastro-enterostomy, where a deep degree of anæsthesia was required, he was unable to produce it, and the surgeon asked him to get the patient more deeply under, but he had failed. That, perhaps, was owing to want of skill, and he was quite ready to be told that he should have tried longer, but in an ordinary hospital this was impossible unless a higher percentage could be obtained. Short of that, he could speak in the

highest terms of the apparatus. It was necessary to be careful of the position of the bottle, but there was no difficulty in warming it with the hand. Up to the present he had no unpleasant experiences, but on that point it was necessary to say a few words. It would be most deplorable if the public thought, and a patient could say, "give me a 2 per cent. and there will be no danger." In giving chloroform at any percentage there was a certain risk; in fact, although the danger might be lessened by using a low percentage, yet there was no absolute immunity. The real action of chloroform was not yet known. There were so many factors to consider that mere percentage dosing was not sufficient to insure safety; for instance, inspiration might be normal but expiration insufficient, and thus the chloroform would accumulate in the system, and the nervous tissues become more and more soaked. There were so many other factors that it was beyond the power of man to say that salvation was in any percentage.

MR. HARVEY HILLIARD observed that he had used the apparatus, and had been very much struck with the quiet way in which anæsthesia had been induced, beginning with .25 per cent. and working up to 1 per cent., which had been sufficient to produce anæsthesia but not to a sufficiently deep degree, and he had had to push on in his first case (which had been the worst and was an abdominal section) to 2 per cent., but this was insufficient to abolish all rigidity. He was working in a temperature of 75° F., but without the specific gravity bulbs, and to try and get a deeper anæsthesia he warmed the bottle, which had only been half filled, with the hand. A little later, however, the boy showing signs of vomiting there was no time to try and deepen the anæsthesia with this apparatus, so he changed to a Skinner, returning to Mr. Vernon Harcourt's apparatus when things were smoother, but with the same result. He agreed with Dr. Dudley Buxton that 2 per cent. was not sufficient to produce a deep enough anæsthesia in all cases, especially some abdominal operations. Mr. Hilliard thought at first that his difficulty was due to the face-piece not fitting, but made sure that it was, for the valves were acting perfectly. Mr. Hilliard also mentioned other cases nearly similar. Induction was perfect in all his cases, four-sixths of which were abdominal, but 2 per cent. anæsthesia was not sufficient to deepen the anæsthesia to dilatation of the pupil, and in one case without warming the bottle he could not abolish the corneal reflex. One most satisfactory case was that of a woman, on whose fœtus craniotomy was performed; anæsthesia was induced and maintained at 1.5 per cent.; the patient remained under satisfactorily except when the head was being crushed, then, however, there was a little straining, and the chloroform bottle had to be filled up to three-quarters and the hand placed round it; this was sufficient to deepen the anæsthesia. The temperature of the room was 60° F. Acting on his experience with the method, the speaker said he now always filled the bottle three-quarters full. In reply to a question by Mr. Norton, Mr. Harvey Hilliard said induction of anæsthesia took about eight minutes. In his first case eight to ten minutes. He considered a slow induction, gradually working up from a low percentage, was best, the induction then being most quiet.

MR. BELFRAGE thought possibly the face-piece and the apparatus might be connected by means of a flexible tube. This would leave the anæsthetist's hands more free.

MR. EASTES wished to know how much liquid chloroform was required to produce a given amount of vapour.

MR. VERNON HARCOURT replied that one volume of liquid chloroform gave 300 volumes at ordinary temperature and pressure.

MR. EASTES remarked that he constantly used Glover's regulating chloroform inhaler, and found it the best apparatus he had ever used. The great advantage was that the measured maximum percentage of vapour was all measured out beforehand, and this, he thought, was better than making your own percentages as the case proceeded.

Dr. McCARDIE being asked for his experience when experimented on with Mr. Harcourt's inhaler, answered that it was short, but pleasant. At first Mr. Dudley Buxton had given him .5 for five minutes, which had had no effect. After an interval of five minutes he had received 1 per cent. : this was very much stronger, so much so that he had lost consciousness in about one and a half minutes. He believed anæsthesia was so deep that conjunctival reflex was abolished. The anæsthesia produced was sufficient for such tests as pinpricks upon his hands, but he did not know if it would be deep enough for abdominal operations. Two per cent. he considered ought to be deep enough for all ordinary operations and for average anæsthesia. But he thought for experts it would be a great advantage if Mr. Harcourt's apparatus could be made to give up to, say, 4 per cent., but for the ordinary medical man it was perhaps an advantage to have the low percentage beyond which he could not go.

Mr. VERNON HARCOURT, in answer to the various questions and suggestions to which his paper had given rise, said, with regard to that about one hand being always employed in raising the temperature, his experience with the bottle was small. He had seen an operation under Mr. Victor Horsley which lasted a full hour. The assistant seemed to have one hand free the whole time, the other feeling the pulse or round the bottle of chloroform. He considered that in the high temperature of a theatre an occasional application of the hand ought to be enough. Certainly something more simple than applying the hand was desirable if it could be found. Concerning the using of more than 2 per cent. he had carefully watched the stop-cock at an operation. The 2 per cent. limit was never reached. He thought that as the common way of giving chloroform was with a loosely-fitting mask, possibly Mr. Hilliard's difficulty to obtain in cases a sufficiently deep anæsthesia was due to his not fitting the face-piece with sufficient accuracy, although the valves might still be working. If only two-thirds of the whole inspiration passed through the apparatus and one-third round the face-piece that would make a very considerable difference in the dose. It is quite easy to increase the percentage of vapour by increasing the size of the bottle. If the cross-section of the bottle were doubled it would give double the percentage of chloroform vapour. In reply to the suggestions of an india-rubber tube, that would be easy, but he was advised to give it up on the ground that the air in the tube would be re-breathed, and that it was best to make the distance as short as possible. There would be no difficulty, if preferred, to have it made so that it stood on a stand, yet these tubes were liable to kink.

Dr. COPESTAKE, of Derby, then showed his apparatus for administering ether, chloroform, or a mixture, and said that the apparatus remained practically the same as that which he described in the year 1900, the only alteration being the substitution of a glass jar to contain hot water to heat the ether when by evaporation it gets too cold, for the less satisfactory method of warming it by the anæsthetist's hand. He also read notes of some 69 cases he had anæsthetised with the apparatus with very satisfactory results. He claimed for the apparatus that the amount of sickness was less than when ether was given in the ordinary way, that the discomfort was less to the patient, and that the consumption of ether was less.

The PRESIDENT asked if gas were given as a preliminary to the ether, and how long it took to induce an anæsthesia.

Dr. COPESTAKE replied that gas was not given and that induction took from eight to ten minutes.

The PRESIDENT remarked that in London they were always in a hurry, and in hospital practice could not spare ten minutes over the induction of each case.

Mr. HARVEY HILLIARD said that he had seen Dr. Copestake use his apparatus that afternoon in one case, and that the result was entirely satisfactory although induction was long.

The meeting then adjourned.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, March 15th, 1902.

ANOTHER SIGN OF PULMONARY TUBERCULOSIS.

M. FERNET read a paper before the Académie de Médecine on the presence of ganglions in the axilla as a precursory sign of consumption. According to the lung affected the adenopathy was found in right or left axilla, and sometimes in both where the lesions were bilateral.

M. Guérin made an interesting communication on the micro-organism of the air, insisting on the utility of antiseptic sprays in hospital wards, preferring for that purpose oxygen water to every other antiseptic. M. Walther considered that the disinfection of the operating room could be easily effected by vapours of formol, and in order to remove the irritating vapours it sufficed to pour on the ground a little liquid ammoniac.

ÆSTHETIC ABLATION OF OVARIAN CYSTS.

In order to avoid an ugly cicatrix produced by laparotomy executed in the classical way M. Morestin adopted a method in the case of two young patients which gave entire satisfaction.

The patient placed in a slight horizontal position, the operator made a transversal incision on the mons veneris, two and a half inches in length, and over the part covered normally with hair. The skin and cellular tissue being cut through and the upper edge of the pubis brought to view, the upper lip of the incision was dissected from the aponeurosis and raised high enough to render apparent the median white line. At this point the peritoneum was opened and the cyst, pressed forward and downward, bulged in the aperture, whence it was quickly evacuated and finally removed, and the wound closed. Six months after the operation the incision was almost invisible.

According to M. Morestier, the operation was applicable whenever the cyst was mobile or but slightly adherent, as was frequently the case in young patients. There was another advantage derived from the method described, perhaps more important than non-disfiguration, and consisted in the fact that by making the incision in the region of the pubis, the walls of the abdomen were not weakened and eventration was not to be feared.

RICKETS.

Prof. Comby, who is an authority on children's diseases, in speaking on rickets, said that the malady was the natural consequence of prolonged digestive troubles in young children, and was to be met with between the ages of ten months and three years. It first appeared in the articulations, wrist and ankles as a hard osseous swelling, painless, and without any sign of inflammation. They took the form of a bracelet around the joints, and might be considered as precursory signs preceding incurvation but disappearing before that deformity. The incurvations or exaggeration of the natural curves of the bones affected notably the legs; the tibia was bent in different directions, convex in front, flattened at the sides (sword-blade); concavity extreme, with the knees touching each other (genu valgum), and the reverse. The genu valgum was the deformity they most frequently met with. The child rarely walked before two or three years of age.

Rickets of the trunk affected chiefly the sternum, the ribs, and the vertebral column, Lesions of the pelvis were inconstant, but should be borne in mind in the female on account of their effect on gestation. Cephalic rickets consisted in frontal and parietal

bony tumours. The anterior fontanelle widely open in the first months closing late (at two years instead of 15 months) was a very important sign of rickets.

The treatment he employed with the best results was:—

Cod-liver oil, 500 grms. ;
Sal. of lacto-phosphate. of lime 50 p.c., 150 grms. ;
Syrup of lacto-phosphate, 350 grms. ;
Gum adigante, 5 grms. ;
Tincture of cinon., 20 grms. ;
Two to five teaspoonsful a day, or
Oil of sweet almonds, 70 grms. ;
Sugar, 30 grms. ;
Phosphorus, 0.01 grm. ;
Ess. of lemons, 2 drops ;
One teaspoonful a day.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 14th, 1903.

At the Medical Society Hr. Levin related a case of
TUBERCLE OF THE KIDNEY.

It was one of pure tubercle of the kidney and bladder with recovery under treatment. The patient had first complained, five years before, of pain in the region of the right kidney. A year later there was tenesmus, desire to micturate so marked that when the patient first came under the speaker's treatment urine had to be passed every ten minutes. The patient weighed 106 lbs., the urine was cloudy, distinctly acid, and contained 20 per cent. albumin, numerous tubercle bacilli, pus cells, but no casts. The right kidney was very much enlarged, easily felt, and tender on pressure. The left kidney was also enlarged. A cystoscopic examination showed ulceration of the bladder, a large ulcer being at the orifice of the right ureter. The case was therefore one of descending grave tuberculosis of the kidney and bladder. The patient was sent to the Jewish Hospital for possible operation, but the surgeon, James Israel, declined this on account of the albuminous urine, and because the condition of the left kidney was doubtful. The speaker then submitted the patient to a course of hygienic dietetic treatment (he had never suffered from fever) and sent him into the country, ordered excessive feeding, local washing out with sublimate solution and creosotic guaiacol injections. The condition had gradually improved, for six weeks the urine had been almost free from albumin, the tubercle bacilli had disappeared from the urine, and inoculation experiments on animals had had negative results. Cystoscopic examination now showed no pathological changes in the bladder. The patient had only to pass urine every two hours, he weighed 131 lbs. and he felt well. Great care was, of course, still necessary. Spontaneous cure in such cases was rare, and had been doubted altogether by some authors.

Hr. Oestreich showed a preparation of
CEREBRAL SYPHILIS.

The disease lay in the left Sylvian fissure of a man, æt. 30. The diagnosis had been made *intra vitam* in the Third Medical Klinik. In the arterial walls, but especially in the external and middle coats, were greyish-yellow foci. In a narrow spot, in the middle of the course of a vessel, not at dividing point, was a small thrombus, also a patch of softening. In the spinal column, discoloration of the cord, no arterial disease, grey infiltration in the arachnoid.

At the meeting of the 16th ult., Hr. Schaedel, of Badenauheim, gave an address on

CHLORIDE OF BARIUM AS A CARDIAC REMEDY.

He said that formerly this drug had been used as a remedy in cardiac cases in place of digitalis, which had

so many drawbacks, but that it since had been forgotten. Lisfranc had recommended it as exercising a tonic effect on the cardiac muscle and on the vessels. It had then, as was often the case with new remedies, been ordered for all sorts of conditions, and it naturally failed, then it was said to be useless. The speaker had experimented with the drug on himself in a horizontal posture, and after a time had noted the pulse frequently and had measured the blood-pressure. The dose given was 0.01 to 0.025 grm., and even 0.08 grm. After a dose of 0.01 grm. no change was noticed. The drug was always taken as a powder, along with some sugar of milk, twice a day, two hours after food, and the effects noted two hours afterwards. When the dose was 0.02 grm. the blood pressure was considerably increased, and the pulse curve showed marked elevation. A similar effect was produced with a dose of 0.05 grm. There were no other after effects. The drug was then tried on patients in the Rostock Clinic in thirteen cases of various forms of heart disease. Here the dose given was 0.02, 0.03, and 0.05 grm. twice or thrice daily. In the case of a woman with mitral insufficiency, with small rapid pulse and low blood-pressure, the latter was distinctly increased, and the pulse became strong and was not slowed. The same effect was produced in the same way two days later. In a second experiment on the same patient the blood-pressure rose as before, the pulse became strong, and the action of the drug was kept up for three days. In a man, æt. 66, with myo degeneration of the heart, a pulse of 72, arrhythmic, œdema of the lips, cyanosis, albumin in the urine, and collapse, so that speedy death was expected, the action of the chloride of barium was striking. After 0.02 the blood-pressure rose, after 0.05 the pulse slowed and the arrhythmia disappeared, the œdema and the cyanosis also disappeared, the appetite became good and only traces of albumin remained in the urine. This patient, who was given up, recovered so as to be able to leave the hospital. In three patients, of ages between 62 and 68, a similar favourable action was noted. In a tailor, æt. 38, with cardiac asthma, the blood-pressure increased to 150 mm. In a case of aneurysm of the aorta, with a blood-pressure of 105 mm. and a pulse of 100, the latter fell after a dose of 0.03 grm. to 78, and the blood-pressure rose to 120. In a man, æt. 20, with mitral insufficiency, the pulse rate also fell with increase of blood-pressure. In a case of nervous tachycardia the pulse became quite normal after a dose of 0.03 grm. Also in a woman with low blood-pressure from great loss of blood, a large rise in blood-pressure took place. He believes that we have in chloride of barium a cardiac remedy far superior to the uncertain digitalis. In reply to a question from Hr. Fraenkel, he said diuresis was increased, and to a question by Aronson he said no effect on the bowels were noted from the small doses employed. The short time at his command had not permitted him to go into the subject more fully on that occasion.

Austria

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 14th, 1903.

TRANSMISSION OF SYPHILIS.

In further discussing Matzenauer's paper on the transmission of syphilis, Kassowitz said that every mother of a syphilitic child was herself syphilitic, and although no symptoms of the disease may have appeared during the pregnancy, condylomata were frequently observed at a later period. The same might be said when a mother was under specific treatment; a healthy child might be born without any appearance of the disease; thus the immunity of the mother could often be explained by the transmission of the toxin to the child while

the antitoxin product may have acted first on the mother. He was not disposed to disagree with the view of several previous speakers, who held that the early descendants of a syphilitic mother were more severely affected than the subsequent offspring—*i.e.*, the intensity of the poison acts so violently on the generative organs that an abortion is the usual event; the next offspring may be premature, and later the intensity fades away until a healthy child is born. The same is true of the father, who may again induce a fresh infection of the mother and give rise to the same cycle. The peculiarity of this poison is the classical separation of its separate stages or manifestations which gradually diminish in intensity until the disease becomes non-infectious in its tertiary stage, which possibly leads to a great deal of confusion in the carefully observed cases.

Riehl brought forward a female who, thirteen years ago, was infected with syphilis. She had now had six abortions and two healthy children, which he thought might be of interest to those taking part in the discussion that was now going on in this association with so much enthusiasm. One of the healthy children was born before the infection of the mother while her first husband was alive, and the second healthy child by the second husband, who was syphilitic, but the birth was long after she had taken a course of specific treatment. Along with this he showed an eight months child with typical hereditary syphilis in the secondary period—papules and syphilitides. It still had the tertiary remnants, such as saddle nose, &c. This one was born some years before the second healthy child.

GANGRENOUS OPERATION OF THE BOWEL.

Ullman showed tissues taken from a female, who after an abortion had perforation of the uterus, which was followed by gangrene of the mesentery and bowel. Laparotomy was performed, and 16 cms. of mesentery removed, the uterus sewn up, and a large segment of bowel removed.

The parts were then attached to the abdomen till stretching was completed, when a decalcified cylinder was inserted in the bowel and the ends brought together. The patient is now in a fair way to perfect recovery.

Eiselberg said that he had often performed this operation without any decalcified cylinder with excellent results.

Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, March 13th, 1903.

At the recent meeting of the Royal Hungarian Medical Society, Dr. Pollacsek brought forward a case of
TOTAL BLINDNESS CAUSED BY NECROSIS OF THE
SPHENOIDAL BONE.

Diseases of the sphenoidal bone play a very important rôle in regard to sight, the reason being obvious. The optic nerve, encapsuled in the foramen opticum, is covered with a very thin bone-plate. On account of this it can be readily understood that the spreading of purulent inflammations to the optic nerve is very probable, and also that the consecutive atrophy of the optic nerve is mostly unilateral. Mendel—on the ground of the cases found in literature, and also those under treatment—states that every case of unilateral atrophy of the optic nerve, which is not brought about by tumours, is undoubtedly produced by the purulent inflammations of the sphenoidal sinus. Bilateral atrophy is of a rarer occurrence, and we assume that it is the

consequence of the pathological change, very extensive, (purulent destroying processes, taking place in the nasal cavity) of both sphenoidal cavities. The primary cause is mostly syphilis.

The patient, æt. 30, suffered from considerable headache for two years, this being specially localised in the occipital region. Four years ago he was afflicted with a nose trouble. Small bone particles have escaped from his nose, and later on, after one year's illness, during which he underwent an anti-syphilitic cure, the bridge of his nose became sunken. Three years ago his sight began to get bad, and it grew steadily worse, so that at last he became totally blind. On this account he went to the ophthalmological clinic, where the following condition was found:—*Synechiæ posteriores oculi dextri, maculæ corneæ, atrophía nervi optici e neuritide oculi utriusque.* Assuming the possibility of a rhinogenic origin, Dr. Pollacsek examined the patient very carefully, in order to detect any rhinological disease. The nasal mucous membrane was yellowish, odourless, covered with dry crusts, the septum—excepting a small piece of it—being entirely wanting. Also the turbinals had been partly destroyed. After cleansing the nose on the right side, at the opening of the sphenoidal duct a little fresh pus was seen. The sound passed went into a small cavity, the size of a hazel-nut. The sound burrowed very easily into the median soft bone-wall of this cavity.

Similar soft bone has been felt also on the left side. In this case the destruction of the bones had spread on the rostrum and body of the sphenoidal bone directly from the septum, and afterwards, causing perineuritis; it had led to atrophy of the optic nerve. Taking into consideration the case being a long-standing one, treatment did not afford much hope as to a quick improvement, as in acute cases. Operative interference is, however, more open to question because if nothing be done we are menaced by complications which can easily occur in the cavernous sinus and on the cerebral membranes.

SIX RECOVERED CASES OF ECTOPIC GESTATION.

Dr. Kubinyi related six cases and showed preparations of ectopic pregnancy. Up to this date, ninety-eight cases of extra-uterine gestation have been treated in the Second Obstetrical Clinic. In the course of last week five cases have been the subject of operation. In two, laparotomy has been necessary by reason of internal hæmorrhage. In the other three cases he had to deal with the consecutive symptoms of rupture of the oviduct. The recovery of all these patients was entirely undisturbed.

A NEW METHOD OF DETECTING THE TUBERCLE BACILLUS IN PLEURITIC EXUDATIONS.

Dr. Zimmermann says that the methods which are employed to ascertain the existence of tubercle bacilli in pleuritic exudations are in some respects wanting. To this it is due that in 50 per cent. of the cases we are unable to arrive at positive results. The reason of this is found in the fact that the number of bacilli contained in pleuritic exudations is comparatively small. In order to be able to cultivate tubercle bacilli from serous pleuritic exudations, we need a nutritive soil of large surface suitable for cultivating the bacilli. The best nutritive soil consists of potatoes mixed with 5 per cent. glycerine solution. But even this is of no avail in recognising the tubercle bacilli from pleuritic exudations, on account of the small extent of the surface within the test-tube, and on account of the small quantity of fluid we can pour over the nutritive soil. We can increase the surface of the soil by cutting long, thin pieces of potato. Five-tenths of a cubic

centimetre of the serous pleuritic exudation, drawn off by means of the needle, is likely to contain one or two bacilli, which will reach the surface of the potatoes. The nutritive soil, prepared according to the above, principle, gave them in all the three cases experimented on, positive results. The potato plates are laid on glass tubes within a glass box prepared correspondingly. The boxes are filled up to the lower surface of the nutritive soil with 5 per cent. glycerinated water, being previously sterilised in an autoclave at 120° C. The whole fluid (5-10 cms.) should be squeezed upon this plate. If the fluid inoculated on the plate contains only one virulent Koch bacillus, it will surely grow there, and on the twenty-first to twenty-third day we can easily recognise the tubercle bacilli in the shape of a colony.

The only disadvantage of this method is its long duration, but its advantage is its simplicity, and the fact that in comparison with the animal experiments the tubercle bacilli can be recognised even when they have lost their virulence.

The President of the Royal Hungarian Society of Pharmacists proposed to the committee the writing of a memorandum to the University College of Physicians of Budapest, requesting the committee to give issue to a decree wherein physicians are warned against writing illegibly. This became necessary on ground of a very sad fact, viz., a boy had brought to a chemist a prescription which contained among others the following: P. cascari. But the writing was so bad that the chemist mistook it for pil. corrosivæ, with the result that the patient, after taking them, succumbed. Otherwise, the chemist had taken every precaution; and he labelled the pills "Poison." The unfortunate chemist was, however, sentenced to two years' imprisonment for his carelessness.

This is a very instructive lesson in favour of doctors taking more care in writing prescriptions.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

INTESTINAL OBSTRUCTION SECONDARY TO PYO-SALPINX.—MR. BATTLE operated on a married woman, æt. about 35, who had been admitted a week previously with symptoms of intestinal obstruction of some four or five days' duration. The symptoms were well marked: vomiting, abdominal pain, with peristalsis, constipation, and distension. The patient had refused to have anything done on admission, and it was only the continuance of pain, although some of her other symptoms were relieved by treatment, that induced her to consent. The abdomen was less distended than when she was admitted, and her condition was somewhat improved, although she looked very ill and had a rapid pulse. When the peritoneum had been opened a large coil of small intestine was found extending towards the pelvis, where it was evidently fixed, as it could not be drawn up, and returning coils were found to be collapsed. In the pelvis was what appeared to be a large uterus, but the right side of this enlargement appeared to fluctuate and was softened, so that the suspicion that it was a pyo-salpinx adherent to the uterus was come to. Posteriorly, also, there appeared to be a kind of sulcus which increased the impression of its nature. The intestines were packed away with gauze plugs and abdominal sponges, and the pyo-salpinx was removed. The pus was yellow and offensive, and escaped from a tear in the enveloping wall during removal; but with con-

siderable difficulty the whole was cleared from the pelvis, and the right side of the uterus ligatured and cut away. After careful cleansing of the parts and changing of sponges, the cause of the intestinal obstruction was investigated; this was due to the fact that a coil of small intestine had become adherent to the back of the pyo-salpinx and then taken an abrupt turn forward, so that it was acutely kinked at that point; it was necessary to separate this from the margin of the cavity that had contained the pyo-salpinx, and although the point of immediate attachment had been much diminished in size, it was not apparently altered in structure, the bowel beyond was empty and small. A second coil was also adherent over a greater extent, but had not been kinked or obstructed in any way, still it took some force to separate it, and the peritoneum was considerably changed where the adhesions had been. The amount of shock resulting from the operation was at first very severe, and it was necessary to give a saline infusion. The glass tube which had been introduced into the pelvis was retained for three days and then removed, as the discharge was without odour and small in quantity, and a stitch which had been inserted at the operation was now tied so as to close the tube opening. The progress was not marked by any rise of temperature, and all symptoms of obstruction ceased. Mr. Battle said that the obstruction was due to an unusual cause; that one hardly expected to find such urgent symptoms dependent upon a disease which was evidently itself of a chronic character. He pointed out that the operation required in the patient's then condition was necessarily very severe, but the woman had to face the risk of removal of the pyo-salpinx and the after freeing of the intestine, as the latter alone might have caused a leakage from the pyo-salpinx at the point of separation, and this must have been followed by a fatal septic peritonitis. In many cases of removal of a pyo-salpinx, especially when the adhesions are dense, he said, the shock is severe, although the patient is in a good condition and ready for the operation; in the present case the woman was already weakened and very ill as the result of some days' intestinal obstruction. The result of the operation was satisfactory, and the patient left the hospital three weeks after operation.

The Medical Act Amendment Bill.

A BILL with this title has been introduced by Sir John Tuke, which is practically the same as that introduced last year. Its object is to extend the penal powers of the General Medical Council and to enable licensing and diploma-conferring authorities to withdraw the diploma of any practitioner whose name has been erased from the *Medical Register*. The Bill is fourth on the list for Friday, April 24th.

Typhus Fever in Glasgow.

SEVERAL cases of typhus fever have occurred in Glasgow, the victims being children inhabiting filthy tenements in the Bridgetown district. The occurrence of this disease at the present day is a reproach to the municipal administration of the locality, and it is assuredly high time that the municipality of Glasgow awakened to a sense of their grave responsibility in the matter.

A Pasteur Institute for India.

THANKS to the munificence of Mr. Henry Phipps, a Pasteur Institute is to be founded in Southern India in order that the inhabitants may enjoy the same benefits as those which have been conferred by the Punjab Institute.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25 Os. 0d.; Half Page 22 10s. 0d.; Quarter Page, 21 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books &c.—Seven lines or under (70 words), 4s. 6d. per insertion 6d. per line beyond.

WEDNESDAY, MARCH 18, 1903.

A PROPHYLACTIC AND CURATIVE SERUM FOR TYPHOID FEVER.

THE Press, lay and medical of the present day is periodically flooded with specious reports of the discovery of preventive and curative sera. Were a tithe of these alleged discoveries founded on fact the era of infectious diseases would be rapidly approaching its close. Unfortunately for the human race, for we cannot admit that the sacrifice of life due to these diseases is a useful phase of the selection of the fittest, the majority of the remedial sera are found wanting so soon as they are weighed in the balance of experience. In spite of repeated discouragements, however, enough good work has been done in this direction—*e.g.*, small-pox, diphtheria, tetanus, and possibly streptococcal infection, to justify the hope that we are on the right track and that products will ultimately be evolved from the laboratories of the world capable of conferring immunity or, what is of infinitely greater importance, of staying the destructive course of the acute infectious diseases which at present deprive the world of such an incalculable number of promising lives. It were greatly to be desired that those who are engaged in this department of research would withhold publicity until their results are commensurate with their hopes. Science would gain in the long run and public confidence in laboratory and clinical research would not be subjected to the oft-repeated strain of disappointment. These remarks are prompted by the paper presented by Lord Lister, on behalf of Dr. Macfadyen, of the Jenner Institute, to the Royal Society, in which the discovery is announced of a serum endowed with marked prophylactic and curative powers in respect of typhoid fever. Coming as it does close upon the very equivocal success of Professor Wright's anti-typhoid serum

a feeling of qualified scepticism is with difficulty resisted. The reputation of Dr. Macfadyen, however, is such that we feel justified in accepting the facts upon which the paper is based, the more so because we may be sure that his conclusions have been carefully scrutinised before being endorsed by Lord Lister and admitted to the honour of a public lecture at the Royal Society. The method of preparation is entirely novel, and is based on the assumption that the virus of the typhoid bacillus is contained in its intracellular juices. These are isolated from the organism itself by a highly ingenious application of natural forces only recently placed at the disposal of the investigator. The bacilli are crushed in liquid air which offers an absolutely neutral medium while providing an exceedingly low temperature incompatible with the occurrence of any secondary changes in the product during the process of manipulation. The intense cold, which has no effect on the vitality of the bacteria, renders possible the process of porphyrisation, and after the latter the bacteria are no longer capable of active life. We are thus placed in possession of a substance containing the active contents of the bacteria apart from the continued vitality of the latter. This substance has been proved by experiments on animals to be powerfully antitoxic and bactericidal, that is to say, it is not only inimical to the living typhoid bacillus but it is also destructive of the virus which it generates in the animal organism. The experiments upon which these conclusions are founded admit of no doubt whatever on this point, but—and the "but" is important—the ultimate test, that of clinical proof on human beings, apparently remains to be applied. Although there is nothing in the information so far rendered accessible to justify the assumption that the effects of the serum have already been tried on the human being, it is highly probable that such has been the case, and we shall await with extreme interest the results that cannot fail to be forthcoming within the near future.

HOSPITAL DECENTRALISATION.

THE determination of the authorities of St. Bartholomew's Hospital to extend their existing premises will naturally rouse a good deal of interest for some time to come in the centralisation of medical charities. For our own part we doubt the wisdom of a policy that locks up in bricks and mortar and in City land of fabulous value a huge sum of money that would suffice to build a suburban hospital on a palatial scale. The St. Bartholomew's authorities, however, think otherwise, and it remains to be seen what view the charitable public will take of the situation. There is little doubt that the money will be forthcoming, even in the times of financial depression that are now being registered by a high income tax and depressed Consols. At the same time it is clear that the gain of St. Bartholomew's will be the loss of other medical charities. The almsgiving capacity of the community stands at a sufficiently steady average to insure that result.

For that matter it would be difficult to find a more striking illustration of the wastefulness begotten of the selfish competition that exists between the hospitals. The question still remains to be answered whether in the case of St. Bartholomew's commensurate advantages will be secured by so great an outlay, especially as the institution stands in the centre of a diminished and still diminishing resident population. The fact is beyond dispute that our great central hospitals are all left more or less derelict by the steady exodus of Londoners from the central districts to the suburbs. In spite of this obvious and vital change of environment, however, some of the hospitals are at the present moment extending their premises and crowding a sick population upon the acreage in a proportion that runs counter to the elementary propositions of sanitary science. It is not surprising to find that other central hospital boards are beginning to turn an introspective eye upon their own position. During the past week it has been announced that St. George's is seriously contemplating the question of removal. In that case we have a large general hospital planted on a costly site in one of the wealthiest districts of London. The area covered by the hospital buildings is so cramped that it is impossible to provide the necessary accommodation for patients and medical and nursing staffs required for the 356 beds which it contains. The acquisition of fresh ground for extension is out of the question, even were it desirable. Owing to its environment there is practically no poor population, and the only excuse, so far as the needs of the district are concerned, is to be found in the large number of domestic servants who reside in the houses of the wealthy. According to the views of some persons, well-to-do employers should be called upon to pay for their sick or disabled servants, rather than hand them over to a public charity. It is true that a certain number of accidents come into St. George's, just as they would come into any hospital in any part of any great city. As we have already pointed out, the removal of a great hospital does not necessarily mean that a sufficient building could not be left behind for the reception of accidents and of acute sickness. We do not for a moment doubt that the field of usefulness of St. George's Hospital could be immensely widened and multiplied by its removal to a suburb, such as Clapham Junction, where hospital accommodation is urgently needed by a large working population. Of late years the critical spirit of the times has shown a determination to thresh out the economic relations of the medical charities to the community at large. There is no other point for a moment comparable with that of hospital centralisation in its far-reaching importance. Those institutions that are wise in their own generations will do well to approach this question in a spirit of anxious and impartial inquiry, and to keep before them the crucial fact that the medical charities owe their existence to the desire of humane persons to alleviate the sufferings of their poorer brethren in the manner

most advantageous, not only to the bestower but also to the recipient of charitable relief.

UNIVERSITY EDUCATION IN IRELAND.

THE long-expected report of the Royal Commission on University Education has at last been issued, and the suspense which existed in many minds has been removed. The Commission has laboured hard to accomplish the task that was set before it. It has sat for many days in different parts of Great Britain and Ireland, and has heard some hundreds of witnesses; it has produced a report which is sixty-seven pages in length, and which contains nineteen general conclusions and recommendations signed by eleven out of the twelve members which constituted the Commission, and, finally, it finishes its labour with a note by the chairman, Lord Robertson, in which he states that, to put it briefly, the scheme prepared by the Commission is an admirable one, provided that it is not adopted. Truly a Hibernian ending to a Hibernian Commission. We cannot here enter into the scheme proposed by the Commission. It is already before our readers in the columns of the daily papers, and our space is limited. There are, however, a few questions which may be asked. What is the cause of such a report, a report which carries on the face of it evidence that it is not meant to be taken seriously? What will be its result? A Commission is appointed to report on a complex subject; it knows its recommendations will not be acted upon; the only statesmanlike solution of the question is tabooed, and the result is a scheme "the best adapted to the complicated situation to which it is applied," but which cannot be recommended for adoption. And yet Lord Robertson's reservation is a very proper one. Can anyone doubt what would be the condition of Ireland in thirty years if the scheme of the Commission were adopted—anyone, that is, who is familiar with the country? Ireland would be divided into two parts by a hard line. The northern and the smaller part would be painted orange on the map, and the southern and the larger would be painted green. The inhabitants of the one, already separated from the other by religion, would then be trebly separated by the absence of every bond that goes to unite communities. There are surely enough bars to the union of north and south in existence without making a greater one, and paying for it with the money of the nation. Still the report is not wholly bad. It contains a paragraph in one of the numerous dissentient notes which, if impressed on the minds of its readers, would go far to save the work of the Commission from complete inutility. The words of Dr. Starkie Resident Commissioner of National Education, are the one redeeming feature of the report: "In my opinion, the national welfare imperatively demands that, during their most formative years, Irishmen should associate together, either in a common college, or, if that is impracticable, less intimately in a common university." Dr. Starkie apparently recognises what so many able men cannot—that what Ireland wishes for is not always

what Ireland requires, and he has the courage to state his opinion. There is no doubt that at present there is a very widely-spread demand for a denominational university. There is even less doubt that the fulfilment of that demand would be fatal to the best interests of the country. The only hope for its future prosperity lies in the co-operation and union of its inhabitants, but co-operation of the kind the Royal Commission terms a federal university is not included in the category. The country is a small one, and distances are every day becoming shorter. What is required is to bring the youth of Ireland together into a national and undenominational university in which the fullest protection is afforded to their several religious convictions, and in which all creeds are upon the same footing, and so to give the country at last an opportunity of getting on speaking terms with itself. Dublin University is the national university of the country in name, and while the present report is being pigeon-holed, it will have an unrivalled opportunity of making itself so in fact. It must, however, if such is to be the case, make concessions. It must look ahead and see what is best for the country, and it must endeavour to afford the Government a just and proper reason for refusing a denominational university, for refusing it, not because one or other denomination wants it, but because undenominational education and the free intercourse of young Irishmen "during their most formative years" are required in the interests of the country. The adoption by the Government of a hand-to-mouth policy has been the cause of many of the past and present ills of Ireland. Is there any hope that such a policy may be discarded in the present case, and one adopted which will lead to the establishment of higher education on the basis of what is statesmanlike and provident, and not on a tottering foundation of expediency?

Notes on Current Topics.

Amateur Physicians.

It is very necessary to sharply distinguish between the motives and methods of the selfish quack and the sympathetic "amateur physician," and Dr. W. S. Colman, in his essay on "Three Distinguished Amateur Physicians," after dealing with the "touching" of the Merry Monarch, Charles II., for the cure of "scrofula" or "King's evil" and the "stroking" of Valentine Greatrakes, the country gentleman and magistrate of Waterford, indicates the efforts of John Wesley in bringing "the healing art" to many sufferers in the eighteenth century. Wesley was a man of wonderful gifts, limitless energy, and wide culture. He was not only a magnificent organiser and an acute controversialist, but a man of deep religious feeling, full of sympathy and tenderness for all sufferers and destitute. "Marriage, dress, diet, and the sanitary arrangements of his community were matters of his constant vigilance, together with care of the poor, a system of loans for the struggling

and provision for the orphans." Wesley was an indefatigable traveller, covering over 250,000 miles in the fifty years of his ministry, and until he was seventy, entirely on horseback. He was therefore intimately acquainted with the ignorance and superstition of the people in all medical and hygienic matters. He clearly saw that much of the medical practice of the day was empirical and often lacking in precision and common sense. His practical mind, therefore, could not rest until he had compiled his "Primitive Physick, or an easy and Natural Method of Curing most Diseases," which to his surprise had at once an enormous sale and yielded handsome profits, which he devoted entirely to charity. The work ran through no less than thirty-six editions, the last appearing as late as 1840. There is much, as might be expected, in this book which at the present day arouses amusement and excites our astonishment at the temerity of the author, but it is clear that in many ways Wesley had a clear grasp of the importance of sanitation, and there can be but little doubt that he considered hygienic conditions quite as important as drug treatment. In our just condemnation of charlatanism and quackery in all its many and varied forms, it is well that we should remember to accord due regard to such "amateur physicians" who in honesty and humility have in days of mediæval medicine sought to furnish help to the helpless.

The Diagnosis of Typhoid Fever.

THE diagnosis of typhoid fever at as early a moment as possible in the course of the disease is a matter of extreme practical importance, but though many pathologists and clinical physicians have endeavoured to find a simple method of making it, it cannot be said that as yet success has crowned their efforts. The much adopted Widal reaction has never been regarded as affording a certain proof, and moreover it rarely furnishes any positive evidence before the second week of the disease. The latest authority to declare its insufficiency is Professor Koch, in his address on the means of suppressing typhoid fever at the Kaiser Wilhelms Academy. Professor Koch disapproves of the Widal method for the reason we have given, and he also condemns all methods which follow the principle of using a medium that delays the growth of the typhoid organisms until after the colonies of *Bacillus coli communis* have attained a vigorous growth. As a result of his research on the subject, he considers the method which has been elaborated by Drigalski and Conradi to be the best. The principle of this is that, instead of retarding the growth of typhoid colonies, their growth is accelerated by means of a culture medium which has a restraining effect upon the large number of intestinal bacteria other than those belonging to the coli group. It then remains to distinguish between the typhoid and coli organisms, and for this purpose the nutrient medium is tinged with litmus, which gives an easily recognised colour distinction

between the strongly acid-forming colonies of coli and those of the *Bacillus typhosus*. The last step in the test consists in confirming the presence of typhoid colonies by the serum agglutination test. Professor Koch considers that he can give a reliable diagnosis by this means in from twelve to twenty-four hours, and thus recognise the presence of typhoid organisms on the second day of the disease.

Psychical Research and Psychological Derangement.

MUCH attention has recently been directed to that section of the realm of the unknown into which so-called "psychical research" students, "spiritualists," and investigators of the perplexities of psychology have sought to throw out experimental "connections." The recent work of Mr. Podmore, the posthumous volumes of Mr. Myers, the address of Sir Oliver Lodge, numberless essays in current periodical literature, revelations in our law courts, and even advertisements in the daily papers and public streets, only faintly indicate the widespread interest and, as we think, at least for some personalities, the dangerous entanglements of a fascination which is not without many serious elements of danger to those of unstable mind and with ill-balanced emotions and mental tendencies which may readily lead to actual psychological derangement. It is useless for medical men to ridicule and scoff at these "recreations" or "researches" as mere manifestations of superstition and idle dealings with "spooks." It is for them to make themselves acquainted with the influences at work in the minds and lives of those who are or may be their patients, and by a recognition of the trend of psychological researches seek to restrain those coming under their direction or seeking their advice from pursuing studies in an unworthy or irrational fashion or confusing the study of physiological and psychological processes with pathological manifestations. Medical men will do well to understand that in the prevailing fashion for so-called "psychical research" there are many elements of danger which a clear understanding and wise discretion may do much to avert.

The Question of Nomenclature.

AT first sight questions of nomenclature may appear to savour of over-niceness, but, to quote from an interesting editorial on the subject in the current number of the *Polyclinic*, names useful, and, indeed, necessary as servants, once bestowed, are apt to become our masters, and thus to acquire undue authority and influence, hence the necessity for selecting them with care. It is a sound general rule that a name should indicate facts and should not imply adhesion to a theory. Failure to conform to this ideal has been responsible for much confusion of thought and for the perpetuation of many erroneous ideas. We have but too often had to protest against a tendency, which still obtains in certain quarters, to dub new remedies with names supposed to be descriptive of their principal therapeutical indications, a practice which cannot fail to be productive of inconvenience

later on when their properties have been more fully investigated. That a name should be as descriptive of facts as possible is an unquestionable advantage; hence the absurdity of using the names of discoverers in this connection, since this gives no clue to the nature or properties of the thing. The worst of it is that even the collapse of a theory does not always entail the disappearance of the name based upon it, for once fixed in the vocabulary it acquires the sanction of custom and tradition, and may survive to confuse and mislead succeeding generations.

The Physiological Action of Boracic Acid.

THE physiological action of boracic acid and its salts is a subject upon which we are urgently in need of precise information in view of their extensive employment as preservatives in articles of food. Dr. Merkel, of Nuremberg, has just published the results of a series of observations undertaken by him on the internal administration of the acid. He gave from fifteen to thirty grains in aqueous solution to a number of patients suffering from slight ailments for periods varying from two to eight days, and he obtained unequivocal evidence of gastro-intestinal irritation. The symptoms were excessive formation of gas in the stomach and intestines with eructations, colic, epigastric pain, and diarrhoea. Invalids proved much more sensitive to its influence than healthy individuals, the latter being able to take moderate doses of the acid without manifest inconvenience. The moral is that boracic acid is not suitable for use as a preservative in articles of food intended for consumption by invalids or by the young; and it is particularly objectionable in milk, since it has to be used in comparatively large quantities, and the adulterated article is likely to be taken by those persons in whom it is likely to cause more or less distressing digestive disturbances.

Conditions Simulating Appendicitis.

IN these days when every practitioner is on the look-out for symptoms of appendicitis, the fact that the symptoms of the latter may be simulated by lesions of very different origin is a matter of considerable interest. The paper on this subject read by Mr. Eve at a recent meeting of the Medical Society of London is, on the whole, rather reassuring than otherwise. He was able, it is true, to refer to five cases of tuberculosis of the cæcum in which the symptoms closely simulated those of appendicitis, and it is evident that malignant disease in this situation might also mislead even an experienced observer. More to the point, because of more frequent occurrence, is the difficulty in some instances of distinguishing between affections of the kidney and gall-bladder, to say nothing of right ovarian mischief, salpingitis, and extra-uterine pregnancy. The fact remains that surgeons themselves often are unable to make a precise diagnosis until they have recourse to an exploratory incision, and the incision is usually made in such a situation as to admit of dealing with one or other of the alternative conditions. The

question which presents itself to the surgeon, indeed, is less whether to operate but when to operate, the precise nature of the lesion being of less importance in regard to the treatment than the inconvenience to which it gives rise and the risk which it entails.

The Dangers of Cheap Thermometers.

FROM the columns of a contemporary we learn that New York has been suffering of late from an epidemic of cheap thermometers which has destroyed hospital records and led to many errors in diagnosis and treatment. The officials of a prominent hospital, whose name is not given, have discovered that the thermometers in use in the wards vary so much as to render valueless the temperature charts which the nurses have made. The physicians have been brought to a rude recognition of the fact that many patients whom they had supposed to have been pyretic had a normal temperature, whilst others had been discharged as cured with temperatures that were far from normal. In some cases variations from the accurate registry of as much as 2.5° F. were found in the thermometers, a variation which might be fraught with the most serious consequences. Our contemporary is distinctly hard upon the hospital authorities, and says that the present intolerable state of things is the inevitable fruit of a policy which endeavours to divorce economy and efficiency. Reliable instruments cost money and cannot be obtained at the cheap rates at which so-called clinical thermometers are frequently sold. The same condition of affairs as existent in New York is probably also in existence in this country. We should greatly like to hear the result of a general testing of thermometers throughout one of our large hospitals, particularly in one in which the nurses are allowed to buy their own instruments. It is not necessary to insist upon the abolition of all cheap thermometers. All that is necessary is to make it the duty of some official of the hospital to hold a monthly inspection of thermometers, comparing them with a standard, and ruthlessly destroying all that are found to possess an error of more than one or, at most, two-fifths of a degree.

Physiological Aberrations in Athletes

THE close observation of long-distance runners, and, in general, of persons addicted to exhausting physical feats, is a study replete with interest and instruction. Such observation enables us to ascertain the immediate and ultimate effects upon the organism, and upon the circulation in particular, of intense physical strain. Judging from the results tabulated by Drs. Blake and Larrabee in a recent communication (a) marked differences were observed in the effects—in this instance after a twenty-four mile run. Although the pulse rate was invariably increased in frequency the increase was very often small, but although the mouth temperature was sometimes above, sometimes

(a) *Boston Medical and Surgical Journal*, February 19th.

below, that of the rectum was always above normal, the difference between the two being often very great, in one instance as much as 7° F. The secretion of urine is lessened, albumin was always present, and the excretion of both urea and chlorides was reduced for the ensuing twenty-four hours. The most marked and constant feature was a fall of arterial tension, but opinions are divided as to the mechanism by which this is brought about. It may conceivably be due to loss of fluid by sweating, or, on the other hand, it may represent an attempt on the part of the nerve centre to relieve the work of the heart by increasing the calibre of the arterioles, the latter view being confirmed by the state of the peripheral circulation as seen in the skin. It is obvious, moreover, that heart fatigue must play a part in bringing about the reduction of tension, it being least marked in those who are in best form. Evidence of cardiac dilatation was observed in a large proportion of the runners, but it was usually ephemeral, hypertrophy being much more common in professional athletes.

Local Therapeutics.

THEORETICALLY when we are called upon to treat disease localised in a particular structure, such as a joint, it would be advantageous to administer the remedy *sur place*, that is to say, in, or in the immediate vicinity of, the part. A drug given by the mouth passes into the blood and only an infinitesimal part thereof can reach the organ at which, so to speak, it is aimed. It follows—or it would follow if the premises were sound—that a much smaller quantity of the drug would suffice to determine the required effect and that the organism as a whole would be spared the perturbation associated with the introduction into a general blood current of a substance foreign to its normal composition. The principle may hold good in a limited class of cases, as, for instance, in the salicylate treatment of a rheumatic affection of one large joint, but its application must necessarily be limited by the fact that although the manifestation may be local the local lesion is, as a rule, merely the expression of a constitutional impairment. Even rheumatism of a large joint is not in reality a purely local disease, since it owes its origin to the existence of what, for convenience, we may term the rheumatic diathesis. Whether mercury could act more energetically if injected in the neighbourhood of a gumma than if given by the mouth is open to question, but it may possibly do so, and there can be no objection to the attempt to influence local manifestations by local measures. Dr. Bouchard, indeed, claims to have obtained marked success by dealing in this way with rheumatic and syphilitic manifestations, and it may be worth while to bear the suggestion in mind in suitable cases.

The Working Life of High-Grade Students.

THERE is a general idea that the most brilliant student does not always prove subsequently to be the most useful and prosperous worker. Pro-

essor E. G. Dexter has sought to submit the problem, as far as it concerns the American student, to serious statistical investigation. His method is, perhaps, open to objections, but his conclusions go to show that the high-grade college man maintains his status in after life. Generally speaking, as regards the medical student, we are of opinion that, as Sir James Paget used to show, what a student was in college days such he usually proved as a practitioner. The worker remained a worker, the loafer continued to shirk. But not a few exceptions are met with, perhaps one of the most striking being that of the great Darwin, whose undergraduate days certainly gave no promise of the rich and strenuous years of painstaking labour and tireless observation. We should be glad to see an analysis made of the medical students who have passed through our British Universities and Metropolitan schools during the past forty years.

Sight-Restoring Pretenders.

ALTHOUGH it is not the "silly season," the readers of the daily Press have been entertained during the past week with much cheap copy on the subject of the alleged discovery by a French professor of a means of making the blind see. Such statements may be treated with the contempt which one is justified in expressing towards those who lay claim to have discovered the secret of perpetual motion. Sight, that is to say, sight with definition of objects, is obviously unattainable except by the aid of a highly-complicated and, unfortunately, exceedingly delicate apparatus, such as we find in the visual organ of man and animals. It may be possible to restore vision when only the parts concerned in the transmission of stimuli are concerned, but when the receptive apparatus or optic nerve has become useless the restoration of useful vision is impossible. Stimulation of certain cerebral areas may conceivably give rise to the sensation of light, but this is the utmost that can be hoped for.

Cerebral Hydatid Cysts.

OF cerebral troubles amenable to surgical treatment one of the most difficult to deal with, and one of the latest to be successfully operated on, is hydatid cyst of the cerebrum. When, in 1890, Dr. Graham and Mr. Grubbe diagnosed in a lad, *æt.* 16, such a cyst, and successfully removed it, they reflected credit on Australian surgery and on the art in general. Fortunately, the case was a favourable one for operative interference. The tumour consisted of a single hydatid cyst which, on opening the dura mater, bulged out and was easily removed. All cases are not, however, so favourable for operation, and in the unfavourable ones Drs. Rennie and Crago recommend that the cyst be removed in two operations, after the method they adopted in October, 1900, in a very unpromising case of a man, *æt.* 29, in New South Wales. The cyst was located in the ascending convolution of the right cerebral hemisphere. Four ounces and a half of fluid were drawn off by a fine trocar, the wound was then closed. Ten days afterwards

Dr. Crago opened the wound afresh and excised the cyst. We think the method recommended, which in the case referred to was attended with success, offers a better chance to the patient in severe cases than the usual one of completing the operation at one sitting, particularly if, as in this case, the cyst be tapped by puncturing it through the dura mater, as Dr. Crago did. When we remember that hydatid cysts have, as Dr. Davies Thompson has shown, penetrated the bone and projected through the cranial bones and been removed by incising the scalp, it seems strange that it did not occur to any surgeon prior to 1890 to trephine the skull and excise them.

Death under Nitrous Oxide.

DEATH so seldom occurs under the influence of nitrous oxide gas that Dr. Maughan deserves the thanks of his professional brethren for bringing his case of death under the influence of the anæsthetic before the Society of Anæsthetists. A young nervous woman was given nitrous oxide gas to facilitate the removal of a tonsil, she being in an easy chair, partly undressed, with a prop between her teeth. Anæsthesia was quickly induced to the stage of loss of light reflex, two breaths of air having been given with the gas. At this point the face-piece was removed, but at the same moment the patient was observed to have stopped breathing. Howard's method of artificial respiration was resorted to, and the operation of laryngo-tracheotomy performed without success. As we read the case we believe the girl died from fright, which paralysed her vaso-motor nervous system, and she bled to death into her veins. In this respect fright and shock are identical in their effects, and that fatal results may follow is common knowledge. In a well-known case a very nervous patient believed the anæsthetic was being administered when he was breathing pure air. After a few gasps he stopped breathing, and in spite of every effort could not be resuscitated. Surgeons must recognise that the patient who dreads an operation is even a worse subject for anæsthesia than the drunkard. Death under anæsthesia brings the most useful class of drugs into popular disfavour, and every death makes the next patient more nervous. For these reasons, if for none other, the utmost care should be taken to safeguard the patient from fright, and unless the operation is urgently necessary, to postpone it until the patient has acquired confidence in his powers of living through the ordeal.

Sterilisation by Cooking.

It is probably only by the process of evolution that man has taken to cooking his food. Primeval man was necessarily in his first days an eater of roots and fruits and of the raw flesh of animals killed in the chase. The practice of cooking meat was most likely acquired at an early period of his cleavage from the rest of the mammals, if we may judge from the evidence of burnt bones in the deep stalactite floors of some of the caves which contain the earliest traces known to us of primeval man.

The conclusion that cooking made meat more valuable to the eater was most likely arrived at by slow degrees, and in the first instance was probably no less fortuitous than the discovery of the virtues of roast pig by the Chinese observer made famous to all succeeding time by the pen of Charles Lamb. Modern science has now put the stamp of scientific approval on the cooking instincts of early man. The exposure of food to a high temperature for a sufficiently long time, says the bacteriologist of to-day, destroys evil-working bacteria, whether the latter be residents or simply visitors. The most recent illustration is yet fresh in the mind of the man in the street, namely, the disastrous nature of imperfectly cooked cockles. Experiment has shown that cockles from contaminated sources are rendered sterile by boiling for three and a half minutes, whereas they contain numerous living and harmful organisms after being boiled for one minute only. The ordinary cooking of the cockles is entirely misleading, as it consists merely of plunging a mass of the shell-fish into boiling water. Similar principles apply to whitebait, mussels, oysters, and other estuary fishery foods.

Further Experience with Diphtheria Antitoxin.

In spite of the early criticisms of the curative value of diphtheria antitoxin the returns from all parts of the world are practically unanimous in confirming its claim to be regarded as the most effectual, indeed, the only trustworthy, agent in averting the lethal consequences of this erst terrible disease. The recently issued report of the Metropolitan Asylums Board shows that the mortality from this disease in the Boards' hospitals which, on the introduction of the antitoxin treatment in 1895 fell from 29.6 to 22.5 per cent., has been still further reduced, since in 1901, on nearly double the number of patients, the proportion of deaths was only 12.5 per cent. The laryngeal cases, taken separately, yielded a mortality of 21.1 per cent., but although comparatively high the figures show a startling reduction on pre-antitoxin days. The most useful lesson to be deduced from the report is that furnished by the comparative statistics in respect of the date of commencement of the antitoxin injections. At the Brook Hospital in 723 cases patients were treated with antitoxin during 1901, with a mortality of 10.79 per cent. In 38 it was possible to commence the treatment on the first day and of these none died; in 170 cases it was begun on the second day with a mortality of 4.1 per cent.; in 192 cases on the third day with 12.4 per cent. of deaths; while in 186 cases it was only begun on the fifth and subsequent days and the mortality attained the maximum figure of 16.6 per cent. It is unnecessary to dilate upon the importance of these figures, especially in view of the fact that at this hospital there has not been a single death among the patients injected on the first day of the disease for five years past. The lesson that appears to be inculcated by these returns is that it is unwise to await bacteriological confirmation of the diagnosis,

but to inject the serum forthwith in every case which clinically appears to be diphtheria. The treatment in itself is harmless if properly carried out and the risk is notably enhanced by every day's delay.

The XIVth International Congress of Medicine, Madrid.

MR. D'ARCY POWER, the Hon Sec., points out that it is of the utmost importance that members of the Congress who intend to visit Spain next month should comply with the requirements of the railway companies in regard to the issue of tickets at reduced rates. Each passenger must be provided with a letter of invitation signed personally by the President of the Congress, and he must send this letter of invitation, with his card of membership (*a*) to Messrs. Cook and Son, Ludgate Circus E.C., and they will make all the necessary arrangements through to the destination; (*b*) to Mons. Sartiaux, Ingenieur en Chef de l'Exploitation, Chemin de Fer du Nord, Paris. Mons. Sartiaux will endorse the letter of invitation, and on its return tickets can be obtained at a reduced rate at Charing Cross or Victoria to Paris. Passengers must re-book in Paris at the Orleans station, and again present their letter of invitation, and it is probable that they must book again at Irun. No letters of invitation have yet been received by members in England so far as is known, and it is desirable, therefore, that each member should write to the Secretary General at Madrid—Dr. Fernandez-Caro, asking that one shall be sent to him as soon as possible. In the eyes of the railway companies the letter of introduction is a much more important document than the card of membership, and unless it is presented properly *vis-à-vis*, no reduction of fare will be granted. Members who wish to travel from Paris by the Sud Express Luxe should book their places beforehand. Sleeping-car places by the night express from Paris should also be engaged beforehand by writing to The Continental Inquiry Office, S.E. and C.R., Victoria Station, S.W. The supplement for place on the First-class fare is rather more than £2.

Exploratory Incision in Gastric Ulcer.

THE treatment of extremely severe and chronic cases of ulcer of the stomach lays a severe tax upon the skill and the patience of the medical attendant. When hæmatemesis has occurred, and all remedies have failed to check the recurrence of pain upon movement and the digestion of moderately soft diet, then the question of an exploratory incision should be considered. If dilatation be present there should be no hesitation in urging the operation, as in that case the removal of cicatricial contractions in the neighbourhood of the pylorus may effect a speedy and brilliant cure. The incision may reveal non-malignant stricture of the pylorus, or an ulcer that may be excised or stitched up in a fold of the outer coat of the stomach. The risk attending a properly performed exploratory incision is so slight—modern surgery has reduced it to something like 5 per cent.—that there need

be no hesitation in advising a patient to submit to the operation, especially when his condition and outlook are deplorable and obstinate to other measures.

Anti-Tuberculous Sera.

THE air is full of claims to priority in the discovery of a serum for the cure of tuberculosis, but the serum itself is still, scientifically speaking *in nubibus*. Dr. Tizzoni, of Bologna (Italy), and Dr. Marmorek, of Vienna, both proclaim their success in the production of a serum which is destructive of the bacillus of tuberculosis. We are not at present in a position to criticise their respective claims, but it is worthy of note that Dr. von Behring, who has succeeded in rendering calves immune to the disease by repeated inoculations, hesitated to apply his method to human beings, warned no doubt by past failures. He, however, advocates the feeding of children, especially those of tuberculous antecedents, on milk from cows which have been inoculated and whose blood is therefore rich in antitoxins. He believes that such children may thereby be rendered proof against tuberculous infection, but he is careful to disclaim the pretension to have discovered a means of protecting or curing adults.

Proposed Sale of the Manchester Royal Infirmary.

DURING past years we have on many occasions drawn attention to the ineffectual efforts which, from time to time, have been made to replace the mediæval Royal Infirmary at Manchester by a hospital worthy of the city and adequate for the needs of its sufferers. Nothing, however, has hitherto been done. At last the City Council, we understand, has offered £400,000 for the present site, and since the old Board of Management has recently been in great measure replaced by the appointment of many progressive citizens, it may be hoped that something will be accomplished without further delay.

Advanced Teaching of Physiology in London.

IN time, it is to be hoped, London University will be a living reality. There are signs that in the near future adequate equipment for the teaching of the fundamental sciences on which effectual medical knowledge must be built up will be provided in or near the Imperial Institute. Already a beginning has been made, and the physiological laboratory and lecture room, illustrations of which appear in the current issue of *Nature*, afford a promise and foretaste of what is in store. Meanwhile, however, London University is only "in making," but we trust the period of development will be expedited.

Accommodation for Post-Mortem Examinations.

IN virtue of the adage "out of sight out of mind," the provision made for carrying out post-mortem examinations in most towns, and even in many districts of the metropolis, is woefully inadequate, not to say disgraceful. The matter is one to which

we have for many years called attention, and little by little improvements are being made. On grounds of both public decency and technical efficiency it is incumbent on well-ordered authorities to provide proper accommodation for the derelict dead and to place at the disposal of practitioners a place in which the necessary facilities for making these examinations are available.

PERSONAL.

SIR JOHN WILLIAMS has retired from practice and is leaving London shortly to take up his residence in Wales.

THE President of the Local Government Board has appointed Mr. Henry Monteith as his honorary assistant private secretary.

SURGEON-LIEUTENANT-COLONEL MATTHEW BAINES, V.D.; Mr. Reginald Harrison, F.R.C.S., and Dr. F. M. Sandwith have been appointed Knights of Grace of the Order of St. John of Jerusalem.

THE Prime Minister has been nominated to the Presidency of the British Association for the advancement of Science at its Cambridge meeting in 1904. It is proposed to hold the gathering for 1905 in South Africa.

PROFESSOR CLIFFORD ALLBUTT, of Cambridge, will give the opening address introductory to the summer Post-graduate Course of Lectures and Demonstrations in connection with the Mount Vernon Hospital for Consumption and Diseases of the Chest.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

OUTBREAK OF TYPHOID.—It was reported at a meeting of the Lisburn Urban Council last week that there was an outbreak of typhoid fever at Stoneyford. No further details have been published, but it is said that there are six cases of typhoid in the catchment area of the Stoneyford reservoir, from which a large part of Belfast is supplied with water. Only a few weeks ago in this column I alluded to the report of the Belfast Water Commissioners, in which it was stated that several farms on the Stoneyford catchment area had been purchased, and from which it was inferred that as far as that part of our supply went we were safe from risk of typhoid. This news is therefore somewhat disconcerting, and it is to be hoped that the Water Commissioners will lose no time in taking vigorous action in the matter.

RISKS OF FIRE.—The authorities of the Belfast District Asylum have decided to take the very wise precaution of having their premises examined by the head of the Belfast Fire Brigade, who will report as to the present means for dealing with an outbreak of fire, and what further means, if any, should be provided.

ACTION AGAINST A BELFAST MEDICAL MAN.—The members of our profession are pleased, and the gossip-mongers deeply disappointed, at the news that the action for breach of promise of marriage brought by a nurse against a well-known Belfast practitioner, who is also a Professor in Queen's College, has been withdrawn. The action has been referred to several times in the daily papers in connection with an application made by the defendant for a change of venue. None of his friends or colleagues, however, believed for a moment

that he had made the statements attributed to him by the nurse and all will be pleased at the collapse of an annoying and costly action.

Correspondence.

DARWIN AND VIVISECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Is there not a good deal to be said on the scientific side of vivisection? You seem to admit this in your leaderette on the above subject.

Apart altogether from emotion and sentiment take the question of the condition of the vivisected animals in experiments on the vaso motor mechanism. In a paper published in the *Journal of Physiology* some thirteen years back on "Plethysmographic Studies," by Messrs. Sewall and Sandford, the writers, say, "It is well, before transferring to human physiology the conclusions arrived at from manipulations of the lower animals in the laboratory, to consider, as far as possible, what might have been the special effect of the conditions of the experiment upon the results obtained."

We are all aware that drugs affect more or less profoundly the whole vaso-motor mechanism, and Dittmar has shown that he found in his experiments that the feeblest stimulative of the sensory nerves—even when so slight as not to be felt by the animals—caused elevation of the blood-pressure.

If you operate on your animals without anaesthetics, or if you do so under the completest and most approved system for the prevention of pain, we have an abnormal state of affairs that must be a very poor guide—in some cases at least—to the indications of normal physiological conditions.

I am, Sir, yours truly,
EDWARD BENROE, M.R.C.S., L.R.C.P. Ed.

** [This argument does not carry us very far. We have to deal with precisely similar conditions of artificially heightened arterial tension in the human being, and although no one pretends that the results can be applied in their integrity to other species of animals than the one experimented upon, any suggestive or other useful deductions may be, and have been, drawn from such experiments and observations.—ED.]

TUBERCULOSIS AND COW'S MILK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The repetition by Dr. Nathan Raw of his opinion that tabes mesenterica is due to the ingestion of infected cow's milk—although he accepts Koch's doctrine that bovine tuberculosis is not communicable to the human subject—compels me again to draw attention to this subject.

Dr. Raw takes up the peculiar ground that "tabes mesenterica and other tuberculous affections," occurring in children, "are probably bovine tuberculosis conveyed by milk, and are not in any way related to human tuberculosis, although the bacillus of Koch is found in them all." This argument appears to me to be self-destructive.

The late Sir R. Thorne-Thorne, while admitting that tuberculosis had diminished to the extent of 50 per cent. among adults in the last quarter of a century, stated that it still claimed a large percentage of the mortality among children, and he founded upon this the argument that this incidence of the disease was due to the fact that children consumed such a large amount of milk—were fed with milk as their chief diet. Now the hard fact is just the very opposite; for it is generally recognised that tabes mesenterica occurs chiefly, if not entirely, among the children of the poor and indigent, who seldom or never have milk as an article of diet properly so-called. But lest it should be thought that, in this statement, I am drawing upon my imagination, like the author just referred to, I beg to call attention to a table published by Mr. R. Henry Rew in the "Journal of the Royal Statistical Society" in June, 1892. In that table Mr. Rew shows that the amount of milk consumed by the various classes of the community is in direct proportion to their purchasing powers, and

in inverse proportion to the incidence of the disease—that is, that the greater proportion of milk consumed the less is the incidence of tuberculosis and *vice versa*. Reduced to figures the extreme proportions come out as follows—viz., West End of London, 34 gallons per head per annum; East End of London, 3 gallons. As Mr. Rew points out, this reveals, incidentally, a significant fact in connection with the dietary of the poor. This is, indeed, a very significant fact, and I should like to know what Dr. Raw thinks of it. Even he tells us of the "pennyworth" of milk bought by poor people, probably for the whole household. To my unsophisticated mind it points clearly to the conclusion that the want of cow's milk is the determining factor, as far as milk is concerned. Otherwise we must assume that the milk consumed in such small quantities is of a different character from that consumed by the well-to-do population—a wholly unwarrantable assumption. In the face of these facts, which go to support Koch's doctrine, I am at a loss to understand how the doctrine of infection by milk can be sustained. Here I would remind Dr. Raw that there is not on record—and I have the authority of Professor Koch for the statement—a single instance which goes to sustain even a suspicion of infection by milk.

It may help Dr. Raw to arrive at a more legitimate conclusion if I also remind him that the injection into the peritoneum of the pus of a psaos abscess or caries—which has not yet been shown to contain the tubercle bacillus—produces the most virulent tuberculous peritonitis characterised by an abundance of tubercle bacilli. Whence, then, have come these bacilli? The more legitimate conclusion, therefore, is that we must look to the amount and character of the food ingested—as food—and not to the presence of bacilli in it, for the determining factor.

I am, Sir, yours truly,
GEO. GRANVILLE BANTOCK.

London, March 14th, 1903.

THE SEMI-TOTAL PLEDGE ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I be allowed to acknowledge the courteous recognition in your columns by the Hon. Secretary of this Association of the mistake in their pledge form on the subject of "total abstinence," to which I called attention in a previous number?

As the declaration now stands it is, I apprehend, one with which no thoughtful mind can find fault, and I think the Association will receive the hearty congratulations of the medical profession on its recent start on the crusade against intemperance. This may, however, appear to the lay mind as a new faith, yet I think I am correct in saying our profession has recognised the soundness of their principle well-nigh from all time. The Association also can embark on its campaign with the conviction and perfect assurance that, whatever the sum total of its achievements in the near or distant future, their efforts can be productive of nothing but good. On the other hand, although the "total abstinence" section of the community have held the field for generations unmolested, they have not consulted the profession as a body on the question of total abstinence as a purely hygienic question, which has, on the contrary, been handled by them often with very discouraging results ever since the scheme was embryonic in conception. What has probably brought the fatal practice of "nipping" between meals into vogue is the increasing struggle for existence among all classes, and those of feeble will power resort to this method of stimulation under the mistaken idea of recruiting exhausted strength, a practice which we know too well can only end, sooner or later, in collapse, and, if my hypothesis be a correct one, it only shows the accuracy of aim the Association has in meeting this difficulty. The doctrine of this Association, viz., "moderation in all things," especially as applied to alcohol, cannot only be truthfully brought home to the rising generation, but can, moreover, be laid down as a dogma and principle in hygiene even in an infant-school,

and it is one, I venture to assert, which secures the general appreciation of our profession.

I am, sir, yours truly,

CLEMENT H. SERS,

Queen's Road, Peckham, S.E., March 12th, 1903.

Literature.

MEDICINE FOR THE MIND. (a)

THIS little brochure may be described as excellent in design and unique in construction, and although no author's name appears on the title-page, and he is content with modestly signing his preface with the initials R. H. B., the diseases are so accurately diagnosed and the remedies withal so judicious of application, that he need not fear adverse criticism should he venture at some future time to attach his name thereto. Needless to say that drugs do not enter into the composition of medicine herein prescribed. It is rather a book of self-help in those many common failings and lapses from perfection in character, to which all are more or less prone, and to which the Baconian precept that "every defect of the mind may have a special recipe" might be applied. The author first describes some "ills of the mind," such as conceit, selfishness, slander, vacillation, despondency, &c., followed by brief practical quotations from ancient and modern philosophers by way of remedies, and he must indeed be a dullard who cannot apply them for his own particular mental affliction. He then gives some general rules for healthy mental life on the principle that it is well to cure but better to prevent a distemper; finally, showing what a solace we may find in Nature, in gardening, art, music, reading, and the like. We have read the little book from cover to cover, its compilation is evidence of great industry, careful thought, and diligent reading of the best authors, and we can only wish that its teaching might become universal, as the world would be better for its adoption.

THE DIAGNOSIS AND TREATMENT OF CONSUMPTION. (b)

DR. ARTHUR LATHAM has been well advised in collecting the various papers dealing with pulmonary tuberculosis, which he has written during the last few years, and issuing them in so convenient and attractive a form as that presented by the book before us. The work is certainly one which is likely to fulfil the author's wish that it may prove "of service as a practical guide to the diagnosis and treatment of pulmonary consumption." The volume is manifestly intended for the busy practitioner and intelligent layman rather than the chest specialist. It is necessarily perhaps somewhat dogmatic in its methods of expression, but the presentation of the subjects dealt with is clear and incisive, and the style is not lacking in a certain amount of literary distinction. The work is divided into chapters which, however, vary much in length and value. The pathological considerations are all too meagre, chief stress throughout being laid on clinical features. Sharp distinction is made between the acute and chronic forms of pulmonary consumption. The former are discussed under (1) the broncho-pneumonic, (2) the lobar pneumonic, and (3) acute miliary forms; while the latter are classified as (1) the fibro-caseous or ordinary form, and (2) the fibroid form. Considerable attention is given to the evidences which should allow of early recognition of the disease. Careful directions are given for the use of Koch's old tuberculin as a diagnostic agent. Dr. Latham is of opinion that tuberculin may prove of much value in assisting the early detection of tuberculosis, and endeavours to show that if rationally employed is free from risk. A very suggestive and practical chapter is devoted to the avoidance of reinfection. Perhaps

(a) "Medicine for the Mind, from the Storehouse of the World's Greatest Thinkers." London: St. Martin's Press, 1903. Price 2s. 3d.

(b)—"The Diagnosis and Modern Treatment of Pulmonary Consumption, with Reference to the Early Recognition, and the Permanent Arrest of the Disease." By Arthur Latham, M.A., M.D. Oxon., M.A. Cantab., Assistant Physician at the Brompton Hospital for Consumption and Diseases of the Chest, &c. Pp. 215. London: Baillière, Tindall & Cox. Price 5s., 1903.

the most interesting portion of the work is that which deals with the principles of the open-air method of treatment as carried out in a sanatorium, and also employed in a private house. Dr. Latham's views will not meet with universal approval, but he nevertheless presents a desirable ideal in a particularly attractive form. And some of his rather too dogmatic assertions will at all events do much to arouse interest and stimulate thought and inquiry. A special section deals with some of the much lauded methods and preparations of recent years such as tuberculin, potassium cantharidate, formic aldehyde, creasote, and urea. One of the most useful chapters to the general practitioner is that dealing with the treatment of special symptoms. This little work should do much to arouse all to the great importance of securing early recognition of the disease and the necessity of providing adequate hygienic treatment in the first stages of the pathological process. We cordially commend Dr. Latham's monograph to the attention of all practitioners.

OBSTINATE HICCOUGH. (a)

WE cannot but admire the industry of the author, who collected and brought together so many cases of hiccough. The symptom is in our opinion common to many widely different pathological conditions, and calls for treatment of the exciting cause. It occurs at all ages from the cradle to the grave, and not unfrequently in aged drunkards it presages death. It is, however, so distressing a symptom when it persists that the profession cannot but be grateful to Dr. Knuthsen for telling us all that is known of it, both of its pathology and its therapeutics. The author classifies the causes as inflammatory, irritative, specific, and neurotic; with this we find no fault, and it will hold its ground until we have fuller information on the subject. As a book of reference Dr. Knuthsen's book fills a useful place in the physician's library, and will doubtless often prove helpful.

THE CLINICAL SOCIETY'S TRANSACTIONS. (a)

WE notice with much pleasure that the Council of this Clinical Society has decided to recommend a revision of the rules of the Society, which prohibits the publication elsewhere of all papers read before the Society. The early publication of new facts is equally in the interests of the medical profession at large and of individual authors. The present volume contains thirty original papers and a large number of reports on the clinical cases exhibited before the Society. In all respects the present volume is fully equal to the best of its predecessors. It is difficult to select from so many interesting papers one to illustrate their excellence. Consequently we select a few dealing with unusual pathological conditions and offering difficulties in diagnosis. Of these some of the more unusual are Mr. Clarke's note on "A Painful Condition of the Twelfth Pair of Ribs"; Mr. Bryant's paper on "Displaced Strangulated Femoral Hernia"; the series of papers on "Operations on the Fifth Nerve"; and Mr. Arthur E. Barker's paper, "Cerebellar Abscess, with Sudden Paralysis of the Respiratory Centres." We know no more useful volume for the physician, and surgeon who desires to keep abreast with the progress of medicine.

YEAR-BOOK OF PHARMACY. (a)

IN the present volume of the "Year-Book of Pharmacy," the medical practitioner will find much interesting matter concerning the practical application of the discoveries of physiological chemistry—discoveries which have led to important results. Of these, one of

(a)—"Obstinate Hiccough: its Pathology and Treatment." By L. F. B. Knuthsen, M.D. Edin. London: J. & A. Churchill, 1902.

(b)—"Transactions of the Clinical Society of London." Vol. XXXV. London: Longmans, 1902.

(c)—"Year-Book of Pharmacy, containing Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foreign Journals from July 1st, 1901, to June 30th, 1902; with the Transactions of the British Pharmaceutical Conference, August, 1902." London: J. & A. Churchill, 1902.

the most interesting is the isolation of adrenalin by Jokichi Takamine, to which he has added a highly instructive, though brief account of its physiological effects. Hardly less important is the separation of the proteolytic enzyme of the thymus gland, by F. Kutscher. The discovery of erapsin by O. Cohnheim is well calculated to modify our views on intestinal digestion, and to modify our dietetic treatment of typhoid fever. We have merely touched the fringe of the wealth of information of this excellent year-book, which we heartily commend to both students and practitioners.

Literary Notes and Gossip.

MOUNTAINEERING has for long proved a favourite pursuit with many members of the learned professions, and not a few medical men have found in the irresistible fascination of the Alps a force which has renewed physical vigour and re-created the powers for mental research. To such Mrs Aubrey Le Blond's new work, "True Tales of Mountain Adventure," will appeal with a peculiar attraction.

MR. ARTHUR SHERWELL, whose work as joint author of "The Temperance Problem and Social Reform" gained for him recognition as a serious student of sociological questions, has recently issued a valuable brochure on "The Drink Peril in Scotland," which seems to indicate that while drunkenness is fortunately diminishing in England, inebriety is seriously increasing among dwellers north of the Tweed. We think Scotchmen would do well to confirm or correct Mr. Sherwell's contentions, for the subject raised has far-reaching hygienic and medical aspects as well as economic and moral considerations.

THE last issue of the *Caledonian Medical Journal*, the representative organ of the society of that name, contains contributions of interest to a wide circle of the profession. The first place has been given to a long and interesting article on the late Rudolph Virchow, physician and scientist, embodying a sketch of his life and citations of his many works and treatises. The other contributions published are entitled "Impressions of a Visit to a German Medical School," "The Requisites of Vision Testing," and "Sprains and their Treatment." This society has now 200 members, and is gradually becoming a more potent influence in the medical world. It is interesting to note a large percentage of its members specialise in mental diseases. Membership is limited to medical graduates of a university who have Celtic blood in their veins, and its aims are the diffusion among its members of professional knowledge.

THE late Sir Walter Besant had the ambition to be the historian of London in the nineteenth century just as Stow had been in the sixteenth, and certainly the work (although in its full design incomplete) which he accomplished places all lovers of the Empire's Metropolis under a lasting debt of gratitude. In the posthumous work recently issued, "London in the Eighteenth Century," which in itself is a monumental volume worthy of its author, and reminding us only too clearly of our loss by his all too early removal, there is much of peculiar interest to medical men. We may refer in particular to the attractive sketch of the condition and position of the members of the healing art in the eighteenth century and the revelation of the extensive quackery which prevailed at that period. A chapter is devoted to "Bedlam," and there are valuable studies relating to the duration of life, food and drink, and other matters connected with the health of the people. Comparisons are not always odious. The twentieth century is brighter than the eighteenth—at least, in things medical.
